-MXR300-32
-MXR300-64
-MXR500-128
-MXR500-256

SAFETY PRECAUTIONS

(Read these precautions before using this product.)

Before using Mitsubishi Electric programmable automation controllers, please read the manuals for the products used and the relevant manuals carefully and pay full attention to safety to handle the products correctly. If products are used in a different way from that specified by manufacturers, the protection function of the products may not work properly.

In this manual, the safety precautions are classified into two levels: "⚠WARNING" and "⚠CAUTION".

⚠ **WARNING**	Indicates that incorrect handling may cause hazardous conditions, resulting in death or severe injury.
⚠ **CAUTION**	Indicates that incorrect handling may cause hazardous conditions, resulting in minor or moderate injury or property damage.

Under some circumstances, failure to observe the precautions given under "⚠CAUTION" may lead to serious consequences.

Observe the precautions of both levels because they are important for personal and system safety.

Make sure that the end users read this manual and then keep the manual in a safe place for future reference.

[Design Precautions]

⚠ WARNING

- Configure safety circuits external to the programmable controller to ensure that the entire system operates safely even when a fault occurs in the external power supply or the programmable controller. Failure to do so may result in an accident due to an incorrect output or malfunction.
  (1) Emergency stop circuits, protection circuits, and protective interlock circuits for conflicting operations (such as forward/reverse rotations or upper/lower limit positioning) must be configured external to the programmable controller.
  (2) When the programmable controller detects an abnormal condition, it stops the operation and all outputs are:
    • Turned off if the overcurrent or overvoltage protection of the power supply module is activated.
    • Held or turned off according to the parameter setting if the self-diagnostic function of the controller detects an error such as a watchdog timer error.
  (3) All outputs may be turned on if an error occurs in a part, such as an I/O control part, where the controller cannot detect any error. To ensure safety operation in such a case, provide a safety mechanism or a fail-safe circuit external to the programmable controller. For a fail-safe circuit example, refer to "General Safety Requirements" in the MELSEC iQ-R Module Configuration Manual.
  (4) Outputs may remain on or off due to a failure of a component such as a relay and transistor in an output circuit. Configure an external circuit for monitoring output signals that could cause a serious accident.
- In an output circuit, when a load current exceeding the rated current or an overcurrent caused by a load short-circuit flows for a long time, it may cause smoke and fire. To prevent this, configure an external safety circuit, such as a fuse.
- Configure a circuit so that the programmable controller is turned on first and then the external power supply. If the external power supply is turned on first, an accident may occur due to an incorrect output or malfunction.
- Configure a circuit so that the external power supply is turned off first and then the programmable controller. If the programmable controller is turned off first, an accident may occur due to an incorrect output or malfunction.
- For the operating status of each station after a communication failure, refer to manuals for the network used. For the manuals, please consult your local Mitsubishi representative. Failure to do so may result in an accident due to an incorrect output or malfunction.
- When connecting an external device with a controller or intelligent function module to modify data of a running programmable controller, configure an interlock circuit in the program to ensure that the entire system will always operate safely. For other forms of control (such as program modification, parameter change, forced output, or operating status change) of a running programmable controller, read the relevant manuals carefully and ensure that the operation is safe before proceeding. Improper operation may damage machines or cause accidents.

[Design Precautions]

⚠ WARNING

- Especially, when a remote programmable controller is controlled by an external device, immediate action cannot be taken if a problem occurs in the programmable controller due to a communication failure. To prevent this, configure an interlock circuit in the program, and determine corrective actions to be taken between the external device and programmable controller in case of a communication failure.
- Do not write any data to the "system area" and "write-protect area" of the buffer memory in the module. Also, do not use any "use prohibited" signals as an output signal from the controller to each module. Doing so may cause malfunction of the programmable controller system. For the "system area", "write-protect area", and the "use prohibited" signals, refer to the user's manual for the module used.
- If a communication cable is disconnected, the network may be unstable, resulting in a communication failure of multiple stations. Configure an interlock circuit in the program to ensure that the entire system will always operate safely even if communications fail. Incorrect output or malfunction due to a communication failure may result in an accident.
- To ensure that the entire system operates safely, configure interlock circuits external to the programmable controller. Failure to do so may result in an accident due to an incorrect output or malfunction.
  (1) OPR (Homing) is controlled by two kinds of data: an OPR direction and an OPR speed. Deceleration is performed when the proximity dog signal turns on. If an incorrect OPR direction is set, motion control may continue without deceleration.
  (2) When the controller detects an error, the operation decelerates and stops or suddenly stops, depending on the parameter settings. Set the parameters to meet the specifications of the system used.
- If safety standards (such as robot safety rules) apply to the system using the controller, drive unit, and servo motor, ensure that the safety standards are satisfied.
- Configure a safety circuit external to the module or drive unit if the abnormal operation of the controller or drive unit differs from the safety directive operation in the system.

[Design Precautions]

⚠ CAUTION

- Do not install the control lines or communication cables together with the main circuit lines or power cables. Doing so may result in malfunction due to electromagnetic interference. Keep a distance of 100mm or more between those cables.
- During control of an inductive load such as a lamp, heater, or solenoid valve, a large current (approximately ten times greater than normal) may flow when the output is turned from off to on. Therefore, use a module that has a sufficient current rating.
- After the programmable controller is powered on or is reset, the time taken for the controller to enter the RUN status varies depending on the system configuration, parameter settings, and/or program size. Design circuits so that the entire system will always operate safely, regardless of the time.
- Do not power off the programmable controller or reset the controller while the settings are being written. Doing so will make the data in the flash ROM and SD memory card undefined. The values need to be set in the buffer memory and written to the flash ROM and SD memory card again. Doing so also may cause malfunction or failure of the module.
- When changing the operating status of the controller from external devices (such as the remote RUN/STOP functions), select "Do Not Open by Program" for "Opening Method" of "Module Parameter". If "Open by Program" is selected, an execution of the remote STOP function causes the communication line to close. Consequently, the controller cannot reopen the line, and external devices cannot execute the remote RUN function.
- The base unit and modules mounted on the base unit must be powered by a power supply that complies with Safety Extra-Low Voltage (SELV) and Limited Energy Circuit (LIM) or one that complies with UL 1310 Class 2.

[Security Precautions]

⚠ WARNING

- To maintain the security (confidentiality, integrity, and availability) of the programmable controller and the system against unauthorized access, denial-of-service (DoS) attacks, computer viruses, and other cyberattacks from external devices via the network, take appropriate measures such as firewalls, virtual private networks (VPNs), and antivirus solutions.

[Installation Precautions]

⚠ WARNING

- Shut off the external power supply (all phases) used in the system before mounting or removing the module. Failure to do so may result in electric shock or cause the module to fail or malfunction.

[Installation Precautions]

⚠ CAUTION

- Use the programmable controller in an environment that meets Page 208 GENERAL SPECIFICATIONS in this manual. Failure to do so may result in electric shock, fire, malfunction, or damage to or deterioration of the product.
- To mount a module, place the concave part(s) located at the bottom onto the guide(s) of the base unit, and push in the module until the hook(s) located at the top snaps into place. Incorrect interconnection may cause malfunction, failure, or drop of the module.
- To mount a module with no module fixing hook, place the concave part(s) located at the bottom onto the guide(s) of the base unit, push in the module, and fix it with screw(s). Incorrect interconnection may cause malfunction, failure, or drop of the module.
- When using the programmable controller in an environment of frequent vibrations, fix the module with a screw.
- Tighten the screws within the specified torque range. Undertightening can cause drop of the component or wire, short circuit, or malfunction. Overtightening can damage the screw and/or module, resulting in drop, short circuit, or malfunction. For the specified torque range, refer to the MELSEC iQ-R Module Configuration Manual.
- When using an extension cable, connect it to the extension cable connector of the base unit securely. Check the connection for looseness. Poor contact may cause malfunction.
- When using an SD memory card, fully insert it into the SD memory card slot. Check that it is inserted completely. Poor contact may cause malfunction.
- Beware that the module could be very hot while power is on and immediately after power-off.
- Do not directly touch any conductive parts and electronic components of the module, SD memory card, or connector. Doing so can cause malfunction or failure of the module.

[Wiring Precautions]

⚠ WARNING

- Shut off the external power supply (all phases) used in the system before installation and wiring. Failure to do so may result in electric shock or cause the module to fail or malfunction.
- After installation and wiring, attach a blank cover module (RG60) to each empty slot before powering on the system for operation. Also, attach an extension connector protective cover[*1] to each unused extension cable connector as necessary. Directly touching any conductive parts of the connectors while power is on may result in electric shock.
  *1 For details, please consult your local Mitsubishi Electric representative.

[Wiring Precautions]

⚠ CAUTION

- Individually ground the FG and LG terminals of the programmable controller with a ground resistance of 100 ohms or less. Failure to do so may result in electric shock or malfunction.
- Use applicable solderless terminals and tighten them within the specified torque range. If any spade solderless terminal is used, it may be disconnected when the terminal screw comes loose, resulting in failure.
- Check the rated voltage and terminal layout before wiring to the module, and connect the cables correctly. Connecting a power supply with a different voltage rating or incorrect wiring may cause fire or failure.
- Connectors for external devices must be crimped or pressed with the tool specified by the manufacturer, or must be correctly soldered.
- Securely connect the connector to the module. Poor contact may cause malfunction.
- Do not install the control lines or communication cables together with the main circuit lines or power cables. Doing so may result in malfunction due to noise. Keep a distance of 100mm or more between those cables.
- Place the cables in a duct or clamp them. If not, dangling cables may swing or inadvertently be pulled, resulting in malfunction or damage to modules or cables.
  In addition, the weight of the cables may put stress on modules in an environment of strong vibrations and shocks.
  Do not clamp the extension cables with the jacket stripped. Doing so may change the characteristics of the cables, resulting in malfunction.
- Check the interface type and correctly connect the cable. Incorrect wiring (connecting the cable to an incorrect interface) may cause failure of the module and external device.
- Tighten the terminal screws or connector screws within the specified torque range. Undertightening can cause drop of the screw, short circuit, fire, or malfunction. Overtightening can damage the screw and/or module, resulting in drop, short circuit, or malfunction.
- When disconnecting the cable from the module, do not pull the cable by the cable part. For the cable with connector, hold the connector part of the cable. For the cable connected to the terminal block, loosen the terminal screw. Pulling the cable connected to the module may result in malfunction or damage to the module or cable.
- Prevent foreign matter such as dust or wire chips from entering the module. Such foreign matter can cause a fire, failure, or malfunction.
- When a protective film is attached to the top of the module, remove it before system operation. If not, inadequate heat dissipation of the module may cause a fire, failure, or malfunction.
- Programmable controllers must be installed in control panels. Connect the main power supply to the power supply module in the control panel through a relay terminal block. Wiring and replacement of a power supply module must be performed by qualified maintenance personnel with knowledge of protection against electric shock. For wiring, refer to the MELSEC iQ-R Module Configuration Manual.
- For Ethernet cables to be used in the system, select the ones that meet the specifications in the user's manual for the module used. If not, normal data transmission is not guaranteed.

[Startup and Maintenance Precautions]

⚠ WARNING

- Do not touch any terminal while power is on. Doing so will cause electric shock or malfunction.
- Correctly connect the battery connector. Do not charge, disassemble, heat, short-circuit, solder, or throw the battery into the fire. Also, do not expose it to liquid or strong shock. Doing so will cause the battery to produce heat, explode, ignite, or leak, resulting in injury and fire.
- Shut off the external power supply (all phases) used in the system before cleaning the module or retightening the terminal screws, connector screws, or module fixing screws. Failure to do so may result in electric shock.

[Startup and Maintenance Precautions]

⚠ CAUTION

- When connecting an external device with a controller or intelligent function module to modify data of a running programmable controller, configure an interlock circuit in the program to ensure that the entire system will always operate safely. For other forms of control (such as program modification, parameter change, forced output, or operating status change) of a running programmable controller, read the relevant manuals carefully and ensure that the operation is safe before proceeding. Improper operation may damage machines or cause accidents.
- Especially, when a remote programmable controller is controlled by an external device, immediate action cannot be taken if a problem occurs in the programmable controller due to a communication failure. To prevent this, configure an interlock circuit in the program, and determine corrective actions to be taken between the external device and controller in case of a communication failure.
- Do not disassemble or modify the modules. Doing so may cause failure, malfunction, injury, or a fire.
- Use any radio communication device such as a cellular phone or PHS (Personal Handy-phone System) 25cm or more away in all directions from the programmable controller. Failure to do so may cause malfunction.
- Shut off the external power supply (all phases) used in the system before mounting or removing the module. Failure to do so may cause the module to fail or malfunction.
- Tighten the screws within the specified torque range. Undertightening can cause drop of the component or wire, short circuit, or malfunction. Overtightening can damage the screw and/or module, resulting in drop, short circuit, or malfunction.
- After the first use of the product, do not perform each of the following operations more than 50 times (IEC 61131-2/JIS B 3502 compliant).
  Exceeding the limit may cause malfunction.
  - Mounting/removing the module to/from the base unit
  - Mounting/removing the terminal block to/from the module
  - Connecting/disconnecting the extension cable to/from the base unit
- After the first use of the product, do not insert/remove the SD memory card to/from the controller more than 500 times. Exceeding the limit may cause malfunction.
- Do not touch the metal terminals on the back side of the SD memory card. Doing so may cause malfunction or failure of the module.
- Do not drop or apply shock to the battery to be installed in the module. Doing so may damage the battery, causing the battery fluid to leak inside the battery. If the battery is dropped or any shock is applied to it, dispose of it without using.

[Startup and Maintenance Precautions]

⚠ CAUTION

- Startup and maintenance of a control panel must be performed by qualified maintenance personnel with knowledge of protection against electric shock. Lock the control panel so that only qualified maintenance personnel can operate it.
- Before handling the module, touch a conducting object such as a grounded metal to discharge the static electricity from the human body. Wearing a grounded antistatic wrist strap is recommended. Failure to discharge the static electricity may cause the module to fail or malfunction.
- Use a clean and dry cloth to wipe off dirt on the module.
- Before starting the operation, check if the brake function operates correctly.
- Before testing the operation, set a low speed value for the speed limit parameter so that the operation can be stopped immediately upon occurrence of a hazardous condition.
- Confirm and adjust the program and each parameter before operation. Unpredictable movements may occur depending on the machine.
- When using the absolute position system, on starting up, and when the module or absolute position motor has been replaced, always perform a homing.
- After maintenance and inspections are completed, check that the positions detected in the absolute position detection are correct.

[Operating Precautions]

⚠ CAUTION

- When changing data and operating status, and modifying program of the running programmable controller from an external device such as a personal computer connected to an intelligent function module, read relevant manuals carefully and ensure the safety before operation. Incorrect change or modification may cause system malfunction, damage to the machines, or accidents.
- Do not power off the programmable controller or reset the controller while the setting values in the buffer memory are being written to the flash ROM in the module. Doing so will make the data in the flash ROM and SD memory card undefined. The values need to be set in the buffer memory and written to the flash ROM and SD memory card again. Doing so also may cause malfunction or failure of the module.
- Do not go near the machine during test operations or during operations such as teaching. Doing so may lead to injuries.
- When the reference axis speed specification is used in interpolation operation, the speed of the partner axis (2nd, 3rd, or 4th axis) may exceed the set speed and ultimately the speed limit value.

[Computer Connection Precautions]

⚠ CAUTION

- When connecting a personal computer to a module having a USB interface, observe the following precautions as well as the instructions described in the manual for the personal computer used. Failure to do so may cause the module to fail.
  (1) When the personal computer is AC-powered
  When the personal computer has a 3-pin AC plug or an AC plug with a grounding wire, connect the plug to a grounding receptacle or ground the grounding wire. Ground the personal computer and the module with a ground resistance of 100 ohms or less.
  When the personal computer has a 2-pin AC plug without a grounding wire, connect the computer to the module by following the procedure below. For power supplied to the personal computer and the module, using the same power source is recommended.
  1. Unplug the personal computer from the AC receptacle.
  2. Check that the personal computer is unplugged. Then, connect the personal computer to the module with a USB cable.
  3. Plug the personal computer into the AC receptacle.
  (2) When the personal computer is battery-powered
  The personal computer can be connected to the module without taking specific measures.

[Disposal Precautions]

⚠ CAUTION

- When disposing of this product, treat it as industrial waste.
- When disposing of batteries, separate them from other wastes according to the local regulations. For details on battery regulations in EU member states, refer to the MELSEC iQ-R Module Configuration Manual.

[Transportation Precautions]

⚠ CAUTION

- When transporting lithium batteries, follow the transportation regulations. For details on the regulated models, refer to the MELSEC iQ-R Module Configuration Manual.
- The halogens (such as fluorine, chlorine, bromine, and iodine), which are contained in a fumigant used for disinfection and pest control of wood packaging materials, may cause failure of the product. Prevent the entry of fumigant residues into the product or consider other methods (such as heat treatment) instead of fumigation. The disinfection and pest control measures must be applied to unprocessed raw wood.

INTRODUCTION

Thank you for purchasing the Mitsubishi Electric programmable automation controllers.
This manual describes the procedures before operation, specifications, functions, devices, parameters, and troubleshooting of the relevant products listed below.
Before using this product, please read this manual and the relevant manuals carefully and develop familiarity with the functions and performance of the controller to handle the product correctly.
When applying the program examples provided in this manual to an actual system, ensure the applicability and confirm that it will not cause system control problems.
Note that the menu names and operating procedures may differ depending on an operating system in use and its version. When reading this manual, replace the names and procedures with the applicable ones as necessary.
Please make sure that the end users read this manual.

Point

The MELSEC MX Controller MX-R Model is used in combination with the MELSEC iQ-R series modules. This manual describes detailed information on the MELSEC MX Controller MX-R Model. For details on the MELSEC iQ-R series modules, refer to their user's manuals.

Relevant products

- MXR300-16, MXR300-32, MXR300-64
- MXR500-128, MXR500-256

Structure of this manual

This section describes the MELSEC MX Controller MX-R Model in the following structures.

- PART 1 to PART 3 describe the contents to be read first.
- PART 4 to PART 6 describe the contents to be referred to when constructing a system.
- PART 7 to PART 15 describe the contents such as the functions and operations of this module.
- PART 16 and PART 17 describe the contents of the required measures for maintenance and troubleshooting.

Item	Description
PART 1 OVERVIEW	What can be achieved with this module
PART 2 PART NAMES	External appearance and LED indications
PART 3 PROCEDURES BEFORE OPERATION	Procedures before operation such as installation, wiring, and the basic parameter settings. The procedure for the program creation is also included.
PART 4 SYSTEM CONFIGURATION	Modules and software that can be used. For the system configuration of the network, refer to Part 5 (COMMUNICATION WITH DEVICES).
PART 5 COMMUNICATION WITH DEVICES	A system configuration of CC-Link IE TSN and Ethernet. Their setting methods are also included.
PART 6 SPECIFICATIONS	General specifications and performance specifications. The motion control and CC-Link IE TSN specifications are also included.
PART 7 CONTROLLER OPERATION	Sequence control scans, program execution, and memory configuration. CC-Link IE TSN communication cycle and motion operation are also included.
PART 8 DEVICES, LABELS, AND CONSTANTS	Devices and labels. A setting method for a device that is required to be set in advance and backup power (latch) for a device is also included.
PART 9 FUNCTIONS	Function overview of the motion control, CC-Link IE TSN, Ethernet, data collection, and security. For details on these functions, refer to each part.
PART 10 MOTION CONTROL	The settings, functions, operation cycle, and each control for performing the motion control
PART 11 CC-Link IE TSN	The cyclic transmission, transient transmission, and other functions of CC-Link IE TSN. For the system configuration and setting procedures to connect with CC-Link IE TSN, refer to "COMMUNICATION WITH DEVICES".
PART 12 Ethernet	Each communication using Ethernet. For the system configuration and setting procedures to connect with Ethernet (SLMP, communication protocol, FTP, OPC UA, and others), refer to "COMMUNICATION WITH DEVICES".
PART 13 DATA COLLECTION	How to collect device values at a specified interval or at a desired timing
PART 14 SECURITY	How to prevent unauthorized access and data outflow
PART 15 ONLINE OPERATION	Online change, remote operation, and monitor performed from the engineering tool
PART 16 MAINTENANCE AND INSPECTION	Daily inspection and periodic inspection. Backup for the various data and firmware update methods
PART 17 TROUBLESHOOTING	Troubleshooting procedure. Error codes and event codes are also included.

17.2 Memory Capacity . . . 330
17.3 File Size Unit in Memory . . . 330
17.4 Number of Storable Files . . . 330
17.5 Number of Storage Folders . . . 331
17.6 Drive Number Definition for Memory . . . 331
17.7 Memory Operation . . . 332
Initialization and value clear . . . 332
17.8 Memory Access Control . . . 334
17.9 Target Memory for All Information Initialization . . . 334
17.10 Files . . . 335
File/folder specifications . . . 335
File types and storage memory . . . 336
File operation available . . . 340
17.11 Specifying Path for Motion Control . . . 342
Drive configuration . . . 342
Specifying path . . . 342
Working folder . . . 344
Precautions . . . 344

PART 8 DEVICES, LABELS, AND CONSTANTS

CHAPTER 18 DEVICES AND CONSTANTS 346

18.1 Device List . . . 346
18.2 Device Setting . . . 347
Range of use of device points . . . 348
18.3 User Device . . . 349
Input (X) . . . 349
Output (Y) . . . 350
Internal relay (M) . . . 350
Latch relay (L) . . . 350
Link relay (B) . . . 350
Annunciator (F) . . . 351
Link special relay (SB) . . . 353
Edge relay (V) . . . 354
Timer . . . 356
Counter . . . 365
Data register (D) . . . 368
Link register (W) . . . 368
Link special register (SW) . . . 368
18.4 System Device . . . 369
Function device (FX/FY/FD) . . . 369
Special relay (SM) . . . 370
Special register (SD) . . . 370

18.5 Link Direct Device . . . 371
Specification method . . . 371
Specification range . . . 371
Difference from link refresh . . . 372
How to access CC-Link IE TSN link device . . . 372
18.6 Module Access Device . . . 373
Buffer memory specification method . . . 374
How to access CC-Link IE TSN link device . . . 374
Precautions . . . 374
18.7 CPU Buffer Memory Access Device . . . 375
Buffer memory specification method . . . 375
How to access CC-Link IE TSN link device . . . 375
18.8 Index Register (Z/LZ) . . . 376
16-bit index modification . . . 376
32-bit index modification . . . 376
Device for which index modification can be performed . . . 377
Index register setting . . . 377
Combination of index modification . . . 378
Precautions . . . 379
18.9 File Register (R/ZR) . . . 380
Specification method . . . 380
Setting file registers . . . 381
Clearing file registers . . . 382
18.10 Refresh Data Register (RD) . . . 382
Refresh memory setting . . . 383
18.11 Nesting (N) . . . 384
18.12 Pointer (P) . . . 385
Global pointer . . . 385
Local pointer . . . 386
Pointer setting . . . 387
18.13 Interrupt Pointer (I) . . . 388
Interrupt factors of the interrupt pointer numbers . . . 388
Priority for the interrupt pointer numbers and interrupt factors . . . 389
18.14 Network No. Specification Device (J) . . . 390
18.15 I/O No. Specification Device (U) . . . 390
18.16 Global Device . . . 390
18.17 Local Device . . . 390
18.18 Device Indirect Specification . . . 395
18.19 Constants . . . 396
Decimal constant (K) . . . 396
Hexadecimal constant (H) . . . 396
Real constant (E) . . . 396
Character string constant . . . 397
Notation of constants . . . 397

CHAPTER 19 LABELS 399

19.1 Global Labels . . . 400
Module label . . . 400
19.2 Local Labels . . . 400
19.3 Classes . . . 401

19.4 Data Types . . . 402
19.5 Arrays . . . 406
19.6 Structures . . . 410
19.7 Label Access Setting from External Device . . . 412
Configuration procedure . . . 414
Global label assignment information . . . 414
Auto-tracking when the label assignment is changed . . . 414
19.8 Precautions . . . 415

CHAPTER 20 LATCH FUNCTION 418

20.1 Device/Label Latch . . . 418
Types of latch . . . 418
Applicable devices and labels . . . 418
Setting latch on devices . . . 419
Setting latch on labels . . . 422
Clearing latch range data . . . 422
Number of points that can be latched . . . 423
When SD memory card is specified . . . 424
Related special relay/special register areas . . . 424
Precautions . . . 425

CHAPTER 21 DEVICE/LABEL INITIAL VALUE SETTINGS 426

21.1 Setting Device/Label Initial Values . . . 426
Setting device initial values . . . 426
Setting initial label values . . . 428
21.2 Applicable Devices/Labels . . . 431
21.3 Device/Label Initialization After Writing . . . 431
21.4 Device/Label Initial Value Reflection After Device/Label Clear Operation Is Executed . . . 431
21.5 Precautions . . . 432

PART 9 FUNCTIONS

CHAPTER 22 FUNCTION LIST 434

22.1 Motion Control . . . 434
22.2 CC-Link IE TSN . . . 437
22.3 Ethernet . . . 438
22.4 Data Collection . . . 439
22.5 Security . . . 439

PART 10 MOTION CONTROL

CHAPTER 23 AXIS SETTING 443

23.1 Axis . . . 443
Relevant variable . . . 443
Maximum number of controlled axes . . . 444
Required settings for axes . . . 444
Axis variables . . . 444
Axis variable initialization timing . . . 445
How to specify in a user program . . . 446

Axis status . . . 446
Precautions . . . 448
23.2 Axis Type . . . 449
Relevant variables . . . 449
Real drive axis . . . 453
Real encoder axis . . . 455
Virtual drive axis . . . 461
Virtual encoder axis . . . 461
Virtual linked axis . . . 465
23.3 Axis Assignment . . . 466
Relevant variables . . . 468
Object data settings . . . 469
PDO mapping setting . . . 470
Setting procedure . . . 470
Memory usage . . . 471
Object data list . . . 472
Motion system function and object data . . . 477
Precautions . . . 477
23.4 Axes Group . . . 478
Relevant variables . . . 478
Relevant FBs . . . 479
Settings required for axes group . . . 479
Axes group variables . . . 479
Axes group variable initialization timing . . . 480
How to specify in a user program . . . 480
Axes group status . . . 480
Axes group enabled . . . 482
Axes group disabled . . . 484
Precautions . . . 486
23.5 Axes Group Assignment . . . 487
Relevant variables . . . 487
Setting with engineering tool . . . 488
Precautions . . . 489

CHAPTER 24 AXIS MANAGEMENT FUNCTIONS 490

24.1 Units . . . 490
Relevant variables . . . 490
Setting methods . . . 491
Precautions . . . 495
24.2 Positioning Range . . . 496
Relevant variables . . . 496
Set position . . . 497
Combination with other functions . . . 498
Precautions . . . 498
24.3 Velocity Range . . . 499
Relevant variables . . . 499
Velocity command range . . . 500
Precautions . . . 500
24.4 Servo ON/OFF . . . 501
Relevant variables . . . 501

Relevant FBs . . . 501
Control details . . . 502
Precautions . . . 503
24.5 Follow Up . . . 504
Relevant variables . . . 505
Disabling follow up . . . 506
Precautions . . . 509
24.6 Absolute Position Control . . . 510
Relevant variables . . . 511
Current position restoration . . . 512
Absolute position data backup . . . 515
Current position restoration for each axis type . . . 517
Required object data . . . 521
Precautions . . . 521

CHAPTER 25 OPERATION CYCLE 522

25.1 Relevant Variables . . . 522
25.2 Motion Operation Cycle Setting . . . 524
25.3 Operation Cycle Assignment . . . 527
25.4 Motion Operation Processing Time Monitor . . . 528
Relevant Variables . . . 528
Control details . . . 528
Precautions . . . 529
25.5 Specifications of Modules on CC-Link IE TSN Configuration Controlled by the Motion System . . . 530
25.6 Send/Receive Data Refresh of Network Connected Devices . . . 531
25.7 Send/Receive Data Refresh of I/O Modules and Intelligent Function Modules . . . 534
25.8 Operation Cycle Coexistence . . . 535
25.9 Precautions for Programming . . . 542

CHAPTER 26 START AND STOP 543

26.1 Start . . . 543
Relevant variables . . . 543
Starting conditions . . . 545
26.2 Retrigger/Continuous Update . . . 546
26.3 Multiple Start (Buffer Mode) . . . 547
Relevant variables . . . 551
Multiple start during single axis operation . . . 552
Multiple start during multiple axes operation . . . 561
Options of buffering FB . . . 569
Near pass . . . 570
Combination with retrigger/continuous update . . . 571
Precautions . . . 576
26.4 Stop . . . 578
Relevant variables . . . 579
Relevant FBs . . . 583
Stop cause lists . . . 584
Types of stop processes . . . 586
Order of priority for stop process . . . 590
Overrun at stop cause occurrence . . . 591
Stop during single axis operation . . . 592

Stop during axes group operation . . . 600
Precautions . . . 608
26.5 Forced Stop . . . 609
Relevant variables . . . 610
Operation at the forced stop occurrence . . . 613
Operation at the forced stop release . . . 615
Check method . . . 616
Precautions . . . 616

CHAPTER 27 HOMING 617

27.1 Overview . . . 617
Relevant variables . . . 618
Relevant FB . . . 618
Homing request . . . 619
Driver homing method . . . 620
Data set homing method . . . 623
Precautions . . . 624
27.2 Operation Setting for Incompletion of Homing . . . 625
Relevant variables . . . 625
FBs that can be started when homing is incomplete . . . 626
Homing request clear . . . 626
Precautions . . . 626

CHAPTER 28 AXIS CONTROL FUNCTIONS 627

28.1 Single Axis Positioning Control . . . 627
Relevant FBs . . . 627
Absolute value positioning control . . . 627
Relative value positioning control . . . 628
28.2 Single Axis Speed Control . . . 629
Relevant FBs . . . 629
Control details . . . 629
BufferMode . . . 630
Required object data . . . 630
28.3 Single Axis Manual Control . . . 631
Relevant variables . . . 631
Relevant FB . . . 631
Types of manual control . . . 631
JOG operation . . . 632
28.4 Multiple Axes Positioning Control . . . 636
Relevant variables . . . 636
Relevant FB . . . 636
Multiple axes positioning control types . . . 637
Operation in multiple axes positioning control . . . 637
Positioning speed in multiple axes positioning control . . . 638
Command unit in the multiple axes positioning control . . . 645
Acceleration/deceleration processing . . . 648
State transition in the multiple axes positioning control . . . 648
Linear interpolation control . . . 649
Circular interpolation control . . . 655
Required object data . . . 664

28.5 Multiple Axes Positioning Data Operation 665
Overall block diagram 666
Relevant variable 666
Relevant FB 666
Control details 667
Positioning data setting 668
Auxiliary function 693
Precautions 708

CHAPTER 29 DIRECT CONTROL 710

29.1 Absolute Position Follow-up Control 712
Relevant variables 712
Relevant FB 712
Control details 713
Relevant object data 714
Precautions 714
29.2 Velocity Control 715
Relevant variables 715
Relevant FB 715
Control details 715
Buffer mode (BufferMode) 717
Relevant object data 725
Precautions 725
29.3 Torque Control 726
Relevant variables 726
Relevant FB 726
Control details 727
Buffer mode (BufferMode) 731
Relevant object data 741
Precautions 741
29.4 Pressure Control 742
Relevant variable 742
Relevant FB 742
Overall block diagram 743
Control details 744
Pressure ramp function 747
Velocity limit acceleration/deceleration processing function 748
Pressure control process 749
Limit position / final position (forward end position) 750
Multiple start (buffer mode) 754
Precautions 757
29.5 Precautions on Direct Control 759

CHAPTER 30 MOTION CYCLIC CONTROL 760

30.1 Motion Cyclic Positioning Control 761
Relevant variables 761
Relevant FB 762
Control details 763
Relevant object data 766
Precautions 766

Program example . . . 767
30.2 Motion Cyclic Velocity Control . . . 768
Relevant variables . . . 768
Relevant FBs . . . 769
Control details . . . 770
Relevant object data . . . 772
Precautions . . . 772
Program example . . . 773
30.3 Motion Cyclic Torque Control . . . 774
Relevant variables . . . 774
Relevant FB . . . 774
Control details . . . 775
Relevant object data . . . 777
Precautions . . . 777
Program example . . . 778
30.4 Precautions on Motion Cyclic Control . . . 779

CHAPTER 31 SYNCHRONOUS CONTROL 780

31.1 Overview of Single Axis Synchronous Control FBs . . . 780
31.2 Axis Configuration . . . 781
31.3 Master Axis Data Source Selection . . . 782
31.4 Stop Operation . . . 783
31.5 Required Object Data . . . 783
31.6 Restrictions . . . 784
31.7 Cam Operation . . . 784
Relevant variable . . . 784
Relevant FB . . . 784
Control details . . . 785
Precautions . . . 815
31.8 Gear Operation . . . 816
Relevant FB . . . 816
Control details . . . 816
Precautions . . . 818
31.9 Addition/Subtraction Positioning . . . 819
Relevant FB . . . 819
Control details . . . 819
31.10 Precautions . . . 821

CHAPTER 32 OPERATION PROFILE DATA FUNCTION 824

32.1 Operation Profile Data . . . 824
Overall block diagram . . . 824
Relevant variables . . . 825
Relevant FBs . . . 825
Operation profile data types . . . 826
Creating operation profile data . . . 861
Operating operation profile data . . . 863
Control of operation profile data . . . 869
Start mode . . . 869
Sub function of operation profile data . . . 871
Precautions . . . 874

32.2 Operation Profile Data Format . . . 875
Operation profile data details. . . . 875
Notation for each setting format . . . 888

CHAPTER 33 ADVANCED SYNCHRONOUS CONTROL 889

33.1 Overview of Advanced Synchronous Control . . . 889
Relevant variables . . . 890
Relevant FBs . . . 894
33.2 Control Details for Advanced Synchronous Control . . . 895
Procedure for executing advanced synchronous control. . . . 896
Starting/stopping for advanced synchronous control. . . . 900
Advanced synchronous control precautions . . . 906
33.3 Input Axis Function . . . 911
Input axis initialization timing . . . 913
Input axis position command unit . . . 913
Input axis positioning range . . . 913
Input axis relevant variables . . . 914
Precautions . . . 919
33.4 Output Axis Function . . . 920
Output axis initialization timing . . . 921
Output axis positioning range . . . 921
Output axis relevant variables . . . 922
Main shaft module . . . 924
Auxiliary shaft module . . . 935
Clutch . . . 947
Speed change gear . . . 960
Output axis module . . . 964
Cam function . . . 972
Synchronous control change function . . . 985
Precautions . . . 989
33.5 Synchronous Control Initial Position . . . 990
Backup data management for advanced synchronous control . . . 991
Restoration method for current position after composite main shaft gear, current position per cycle after main shaft gear, and current position per cycle after auxiliary shaft gear at start of synchronous control . . . 992
Cam axis position at synchronous control start . . . 995
Synchronous control analysis mode . . . 1003
Variables related to synchronous control initial position . . . 1005
Precautions . . . 1008
33.6 Cam Position Calculation Function . . . 1009
Control details . . . 1009
Precautions . . . 1015
33.7 Application Function . . . 1016
Phase compensation function . . . 1016
33.8 Example Programs . . . 1019
Flying shear . . . 1019
Filling machine . . . 1029

CHAPTER 34 FUNCTIONS RELATED TO POSITION 1054

34.1 Current Position Change Function . . . 1054
Relevant FB . . . 1054

Current position change 1055
Cancel 1058
34.2 Command In-position 1059
Relevant variables 1059
Command in-position range check 1060
34.3 Software Stroke Limit 1061
Relevant variables 1061
Definition of movable range 1062
Specifications of the software stroke limit check 1068
Precautions 1068
34.4 Hardware Stroke Limit 1069
Relevant variables 1070
Hardware stroke limit check details 1073
Returning from outside the hardware stroke limit range 1074
Checking whether the hardware stroke limit is enabled/disabled 1075
Precautions 1075

CHAPTER 35 FUNCTIONS RELATED TO VELOCITY 1078

35.1 Acceleration/Deceleration Processing Function 1078
Relevant variables 1080
Acceleration/deceleration method 1084
Acceleration/deceleration waveform adjustment when specifying jerk 1092
Operation when specifying acceleration/deceleration 0 1094
Acceleration limit value/deceleration limit value 1096
Jerk limit value 1097
Limit of acceleration time/deceleration time 1098
Automatic deceleration 1099
Changing control of jerk acceleration/deceleration 1100
Acceleration/deceleration method and multiple start 1106
Velocity bias 1108
Precautions 1110
35.2 Velocity Limit 1112
Relevant variables 1112
How to set the velocity limit function 1112
Operation when the velocity limit value is exceeded 1113
Operation Setting at Velocity Limit Value Exceeded 1115
35.3 Override Function 1116
Relevant variables 1117
Relevant FBs 1118
How to change control data 1118
Precautions 1123

CHAPTER 36 FUNCTIONS RELATED TO TORQUE 1124

36.1 Torque Limit 1124
Relevant variables 1124
Object data settings 1125
Torque limit value setting range 1125
Torque limit maximum value setting range 1126
Precautions 1126

36.2 Torque Limit Value Change Function 1127
Relevant variables 1127
Relevant FB 1127
How to change control data 1128

CHAPTER 37 COMPENSATION FUNCTION 1129

37.1 Relevant Variables 1129
37.2 Driver Unit Conversion Function 1130
Control details 1131
Precautions 1132

CHAPTER 38 COMMAND FILTER 1133

38.1 Relevant FBs 1133
38.2 Smoothing Filter 1134
Program example 1135
Precautions on smoothing filter 1136
Required object data 1136
38.3 Moving Direction Restriction Filter 1137
Program example 1137
Required object data 1137
38.4 Speed Limit Filter 1138
Program example 1138
Required object data 1138
38.5 Backlash Compensation Filter 1139
Procedure to enable the backlash compensation filter 1142
Program example 1142
Precautions on backlash compensation filter 1145
Required object data 1145
38.6 Precautions on Command Filter 1145

CHAPTER 39 INPUT VARIABLE CHANGE IN EXECUTION 1146

39.1 Relevant Variables 1146
39.2 Target Position/Movement Distance Change 1147
Target position change 1147
Movement distance change 1148
The deceleration distance is not kept by the target position/movement distance change 1149
When an operation is reversed by changing the target position/movement distance 1150
39.3 Command Velocity Change 1151
Command velocity sign inversion during speed control 1151
Combination with override 1151
Operation during interpolation control 1152
39.4 Acceleration/Deceleration and Acceleration/Deceleration Time Change 1153
39.5 Precautions 1153

CHAPTER 40 EXTERNAL SIGNAL SELECTION 1154

40.1 Overall Block Diagram 1154
40.2 Relevant Variables 1155
40.3 SIGNAL_SELECT Structure 1156
40.4 TARGET_REF Structure 1158
40.5 External Signal High-Accuracy Input 1164

40.6 External Signal High-Accuracy Output . . . 1164
40.7 Precautions . . . 1165

CHAPTER 41 TOUCH PROBE 1166

41.1 Overall Block Diagram . . . 1166
41.2 Relevant FBs . . . 1166
41.3 Touch Probe Enabled . . . 1167
Control details . . . 1167
Precautions . . . 1171
41.4 Touch Probe Disabled . . . 1172
Control details . . . 1172
41.5 Precautions . . . 1174

CHAPTER 42 DIGITAL CAM SWITCH 1175

42.1 Overall Block Diagram . . . 1175
42.2 Relevant Variables . . . 1176
42.3 Relevant FB . . . 1176
42.4 Control Details . . . 1177
Switch settings . . . 1179
Time compensation . . . 1182
Signal output timing . . . 1183
42.5 Precautions . . . 1185

CHAPTER 43 AXIS EMULATION 1186

43.1 Relevant Variables . . . 1187
43.2 Setting Procedure . . . 1187
43.3 Operation During Emulate Function . . . 1187
43.4 Specifications of the Emulated Device Station . . . 1188
Feedback data specifications . . . 1188
43.5 Precautions . . . 1189

CHAPTER 44 AXIS CONTROL WAIT 1190

44.1 Overall Block Diagram . . . 1190
44.2 Relevant Variables . . . 1190
44.3 Relevant FBs . . . 1191
44.4 Axis Control Start Wait . . . 1191
Timing chart . . . 1192
Execution permission signal . . . 1196
44.5 Axis Group Control Start Wait . . . 1197
Timing chart . . . 1198
Execution permission signal . . . 1199
44.6 Program Example . . . 1200
44.7 Precautions . . . 1202

CHAPTER 45 PROGRAM EXAMPLES 1203

45.1 Project Structure . . . 1203
Program name . . . 1203
45.2 PLC READY (Program Name: ServoON_Jog) . . . 1204
45.3 Servo ON (Program Name: ServoON_Jog) . . . 1204
45.4 JOG Operation (Program Name: ServoON_Jog) . . . 1205

45.5 Homing (Program Name: Homing) . . . 1209
45.6 Single Axis Positioning Control (Program Name: Positioning) . . . 1211
45.7 Single Axis Continuous Positioning (Program Name: ContinuousPositioning) . . . 1213
45.8 Interpolation Control (Program Name: LinearInterpolation) . . . 1217
Procedure for interpolation control . . . 1217
Enabling/disabling an axes group . . . 1217
Interpolation control . . . 1217
Program example for linear interpolation . . . 1218
45.9 Synchronous Control (Program Name: Synchronous) . . . 1223
Procedures for executing synchronous control . . . 1223
Operation profile data . . . 1224
Single axis synchronous control FBs . . . 1226
Axes configuration . . . 1226
Program example for synchronous control . . . 1227
45.10 Error Reset (Program Name: ErrorReset) . . . 1232

PART 11 CC-Link IE TSN

CHAPTER 46 CYCLIC TRANSMISSION 1234

46.1 Communications Using RX, RY, RWr, and RWw . . . 1235
46.2 Link Refresh . . . 1236
Setting method . . . 1237
Transmission delay time shortening method . . . 1239
46.3 Direct Access to Link Devices . . . 1241
46.4 Cyclic Data Assurance . . . 1244
46.5 I/O Maintenance Settings . . . 1247
Output settings during STOP or error . . . 1248
Data link error station setting . . . 1250
46.6 CANopen Communications . . . 1251
PDO communication using cyclic transmission . . . 1251
SDO communication using transient transmission . . . 1253

CHAPTER 47 TRANSIENT TRANSMISSION 1254

47.1 Communications Using the SLMP . . . 1254
47.2 Routing . . . 1255
Dynamic routing setting . . . 1255
Routing setting . . . 1255

CHAPTER 48 OTHERS 1257

48.1 Reserved Station Setting . . . 1257
48.2 Error Invalid Station Setting . . . 1257
48.3 Time Synchronization . . . 1257

PART 12 Ethernet

CHAPTER 49 SLMP COMMUNICATION 1260

49.1 Applications . . . 1260
49.2 Difference Between Ports for CC-Link IE TSN and Ports for Ethernet . . . 1261
49.3 Communication Structure . . . 1261

49.4 Data Communication Procedures 1262
49.5 List of Valid Commands 1264

CHAPTER 50 SIMPLE CPU COMMUNICATION FUNCTION 1266

50.1 Setting Method. 1269
Setting for each communication destination 1270
Encrypted communication settings 1278
Import/export of settings 1279
Executing simple CPU communication 1281
50.2 Checking the Simple CPU Communication Status 1287
How to check using the buffer memory 1287
Checking with "simple CPU communication diagnostics" 1289
50.3 Precautions 1289

CHAPTER 51 PREDEFINED PROTOCOL COMMUNICATIONS 1291

51.1 Applicable Connections 1292
51.2 Data Communication Procedures 1293
51.3 Protocol Communication Type. 1300
51.4 Packet Elements 1301
51.5 Execution Conditions of Predefined Protocol Communications 1307
51.6 Example of Predefined Protocol Communications 1308

CHAPTER 52 SOCKET COMMUNICATIONS 1318

52.1 Setting Method. 1320
52.2 Dedicated Instructions 1321
52.3 Applicable Connections 1321
52.4 Communication Structure 1322
52.5 Communications Using TCP 1323
52.6 Communications Using UDP 1326
52.7 Broadcast Communications. 1326
52.8 Precautions 1327
52.9 Communication Example 1328
Socket communication example 1328
Communication example of re-open processing 1342

CHAPTER 53 FTP FUNCTIONS 1345

53.1 FTP Server 1345
Supported communication modes 1346
FTP server settings 1347
Data communication procedures 1349
Files that can be transferred with FTP. 1352
FTP commands 1353
Precautions 1361
53.2 FTP Client. 1367
Encrypted communication settings 1368
Transferable files 1375
FTP client settings 1375
Procedure for executing the file transfer function (FTP client) 1376
Precautions 1378

CHAPTER 54 WEB SERVER FUNCTION 1379

54.1 Web Server Function Specifications 1381
54.2 System Configuration 1382
54.3 Operation Method/Procedure 1383
Downloading the system Web page library 1383
Module parameter setting 1384
Writing the system Web page 1387
How to access the Web server 1388
Logon/logoff 1389
54.4 Function Details 1390
Detailed Module Information (Module Information) 1391
Device Monitor 1392
Watch 1394
CPU Diagnostics 1395
Event history 1396
Program monitor 1397
User Web page 1399
System Web page update 1399
Display update interval 1399
Language switcher 1400
54.5 User Web Page 1401
Accessing User Web Page 1402
54.6 Error message 1403
54.7 PRECAUTIONS 1404

CHAPTER 55 OPC UA COMMUNICATION FUNCTION 1405

55.1 OPC UA Communication Function 1405
Specifications 1406
Procedure of OPC UA server startup 1415
OPC UA server startup/stop 1421
OPC UA server function list 1424
Precautions 1427

CHAPTER 56 OTHERS 1430

56.1 Network Setting Change Function 1430
IP address of the controller 1431
How to use 1432
Checking the IP address 1435
Checking the operating status 1435
Precautions 1436
56.2 DNS Client Function 1437
DNS settings 1437
56.3 Discard Received Data at CPU STOP 1438
Setting method 1438
Precautions 1438

PART 13 DATA COLLECTION

CHAPTER 57 DATA LOGGING FUNCTION 1440

57.1 Data Logging Procedure . . . 1441
57.2 Specifications . . . 1442
57.3 Data to Be Collected . . . 1444
Number of data points . . . 1444
Data type and output format . . . 1444
Data to be collected . . . 1446
57.4 Data Collection Conditions . . . 1448
Each scan . . . 1448
Time specification . . . 1448
Condition specification . . . 1449
Network communication cycle synchronization . . . 1451
After the execution of specified program . . . 1452
57.5 Logging Types . . . 1453
Operating procedure for continuous logging . . . 1453
Operating procedure for trigger logging . . . 1454
57.6 Data Logging File . . . 1460
Storage format of data logging files . . . 1460
Binary file output format . . . 1461
Unicode text file output type . . . 1465
CSV file output format (Shift-JIS) . . . 1471
CSV file output format (Unicode) . . . 1477
JSON file output format . . . 1483
Output content details . . . 1497
57.7 States of the Data Logging Function . . . 1499
Data logging states . . . 1499
57.8 Steps Until the Collected Data Is Saved . . . 1500
Internal buffer . . . 1501
Switching to a storage file . . . 1503
57.9 Missing Data . . . 1509
Conditions under which missing data occurs . . . 1509
57.10 Data Logging File Transfer to Data Memory . . . 1510
57.11 Logging Start Condition Setting . . . 1511
57.12 Auto Logging . . . 1512
57.13 SD Memory Card Replacement . . . 1517
57.14 SD Memory Card Life When the Data Logging Function Is Used . . . 1519
57.15 Special Relay and Special Register Areas Used by the Data Logging Function . . . 1520
57.16 Precautions to Take When Using the Data Logging Function . . . 1521

CHAPTER 58 SEQUENCE SCAN SYNCHRONIZATION SAMPLING FUNCTION 1531

PART 14 SECURITY

CHAPTER 59 LIST OF SECURITY FUNCTIONS 1534

CHAPTER 60 PROTECTION OF INFORMATION ASSETS IN THE CONTROLLER 1536
60.1 User Authentication Function 1536
User authentication 1537
Management information (user management information and user group management information) 1538
User group 1539
Access to the controller 1542
How to operate the user authentication function 1544
Restrictions on using the user authentication function 1552
Precautions 1554
60.2 File Tamper Check Setting 1555
Target files 1555
60.3 All Information Initialization of Controller 1556
Setting method 1556
LED indicator 1557
CHAPTER 61 PROTECTION OF THE NETWORK CONNECTED TO THE CONTROLLER 1558
61.1 Encrypted Communication Function 1558
Digital certificate 1559
"Certificate Management" window 1564
Operation procedure for the encrypted communication 1571
Certificate expiration check 1580
Closing connections for encrypted communication 1580
Precautions 1581
61.2 IP Filter Function 1582
Setting procedure 1582
Operation 1584
Precautions 1584
61.3 Default Open Port Usage Setting Function 1585
Setting method 1585
61.4 Band Limit Function Against DoS Attacks 1588
Setting method 1588
Precautions 1590
CHAPTER 62 PROTECTION OF CONTROLLER OPERATION 1591
62.1 Operation Settings 1591
PART 15 ONLINE OPERATION
CHAPTER 63 WRITING DATA TO THE CONTROLLER 1594
63.1 Writing Data to the Programmable Controller 1594
63.2 Online Change 1594
Convert + Online change 1594
File batch online change 1598
63.3 Precautions 1599
CHAPTER 64 REMOTE OPERATION 1606
64.1 Remote RUN/STOP 1606
Executing method 1606

Operation at device/label memory clear 1607
Precautions 1607
64.2 Remote PAUSE 1608
Executing method 1608
64.3 Setting RUN-PAUSE Contacts 1609
64.4 Remote RESET 1610
Remote reset setting 1610
Executing method 1610

CHAPTER 65 MONITOR FUNCTION 1611

65.1 Performance Monitor 1611
65.2 Real-time Monitor 1612
65.3 Position Data History 1613

PART 16 MAINTENANCE AND INSPECTION

CHAPTER 66 MAINTENANCE FUNCTION LIST 1616

CHAPTER 67 DAILY INSPECTION 1618

CHAPTER 68 PERIODIC INSPECTION 1620

68.1 Battery Replacement Procedure 1621

CHAPTER 69 CONTROLLER DATA BACKUP/RESTORATION FUNCTION 1622

69.1 Backup 1630
Backup using engineering tool 1632
Backup processing triggered by turning on SM1351 1633
Automatic backup using engineering tool 1634
Automatic backup using SD944 1636
Precautions 1639
69.2 Restoration. 1643
Automatic restoration using engineering tool 1644
Automatic restoration using SD955 1646
Checking restoration errors 1646
Precautions 1647

CHAPTER 70 SOFTWARE UPDATE OF THE CONTROLLER 1650

70.1 Firmware Update Function 1650
70.2 Add-on Function 1663
Add-on type 1663
Memory specifications 1663
Operating procedure 1664
Safe mode 1668
Label list 1669
Precautions 1670

PART 17 TROUBLESHOOTING

CHAPTER 71 TROUBLESHOOTING FUNCTION LIST 1672

CHAPTER 72 TROUBLESHOOTING PROCEDURE 1674

72.1 Troubleshooting with LED Indicators . . . 1674
When the READY LED or PROGRAM RUN LED turns off . . . 1674
When the ERROR LED turns on or is flashing . . . 1675
When the D LINK LED turns off or is flashing . . . 1676
When the L ER LED turns on . . . 1677
When the LINK LED turns off . . . 1678
When the dot matrix LED is alternately repeating the station number display and ERR display . . . 1679
When S-ERR is displayed on the dot matrix LED . . . 1679

72.2 Checking the Module Status . . . 1680
System monitor . . . 1680
Module diagnostics . . . 1681
Event history . . . 1683

72.3 Checking Status of Motion Function . . . 1684
Checking errors and warnings . . . 1684
Error and warning reset . . . 1686

72.4 Checking the Network Status . . . 1697
CC-Link IE TSN/CC-Link IE Field diagnostics . . . 1697
Ethernet diagnostics . . . 1707
OPC UA server diagnostics . . . 1712
Communication test . . . 1713
Station information list . . . 1714
Remote operation . . . 1715
Monitoring link special relay (SB) and link special register (SW) . . . 1716

CHAPTER 73 TROUBLESHOOTING BY SYMPTOM 1717

73.1 Programmable Controller Function Troubleshooting . . . 1717
When data cannot be written to the controller . . . 1717
When data cannot be read from the controller . . . 1717
When the operating status of the controller cannot be changed . . . 1717

73.2 CC-Link IE TSN Troubleshooting . . . 1718
When cyclic transmission failed . . . 1718
When transient transmission failed . . . 1721
When a station is disconnected from the network . . . 1723
When a station is repeatedly disconnected and reconnected . . . 1723
When communications are unstable . . . 1725
When communications using the SLMP cannot be performed . . . 1725
When communications with Ethernet devices failed . . . 1726
When communications for the link device failed although the data link is normal . . . 1726
When the network map or selected station communication status monitor is not displayed correctly . . . 1727
When communications cannot be performed with the external device while the default open port is used . . . 1727
When CC-Link IE TSN Class A device does not perform data link . . . 1728
When invalid information is displayed in the event history or detailed information of the module diagnostics window . . . 1730
When a synchronous communication error is detected in a device station . . . 1730

73.3 Ethernet Troubleshooting . . . 1731
When communications cannot be performed with the external device . . . 1731
When communications cannot be performed with the external device during encrypted communication . . . 1732
When communications cannot be performed with the external device while the default open port is used . . . 1732
When a message sent from the external device cannot be received frequently . . . 1732

When communications using the Ethernet port are slow . . . 1733
When direct connection to the engineering tool is not possible. . . . 1733
When the CPU module or CC-Link IE TSN-equipped module search on the network cannot be performed . . . 1733
When communications using the SLMP cannot be performed . . . 1734
When communications using the predefined protocol cannot be performed. . . . 1734
When socket communications cannot be performed. . . . 1735
When access using the file transfer function (FTP server) cannot be performed . . . 1735
When access using the file transfer function (FTP client) cannot be performed . . . 1736
When using the Web server function. . . . 1737
When the simple CPU communication function is used . . . 1739
When communications cannot be performed with the OPC UA server . . . 1740
When the time setting function (SNTP client) cannot be performed normally . . . 1741
When the access cannot be allowed/denied correctly by the IP filter . . . 1741
73.4 Motion Function Troubleshooting . . . 1742
When Servo ON failed. . . . 1742
When a motor does not rotate . . . 1742
When motion control cannot be used . . . 1742

CHAPTER 74 RAS FUNCTIONS RELATED TO TROUBLESHOOTING 1743

74.1 RAS Functions of Programmable Controller . . . 1743
Scan monitoring function . . . 1743
Self-diagnostic function . . . 1745
Error clear . . . 1751
Event history function . . . 1754
74.2 CC-Link IE TSN RAS Functions . . . 1767
Device station disconnection . . . 1767
Automatic return . . . 1767
Master station duplication detection . . . 1767
IP address duplication detection . . . 1768
Module communication test. . . . 1769
LED display of data link faulty station . . . 1770
74.3 Ethernet RAS Functions . . . 1771
Timer settings for data communication . . . 1771
Ethernet communication load monitor function . . . 1775
IP address duplication detection . . . 1775

CHAPTER 75 ERROR CODES 1776

75.1 Error Code System . . . 1776
75.2 How to Clear Errors. . . . 1777
75.3 Codes of Errors Detected by Self-diagnostic Function (1000H to 3FFFH) . . . 1778
75.4 Error Codes Returned to Request Source During Communications (4000H to 4FFFH). . . . 1850
75.5 Codes of Errors Detected by Other Than the Self-diagnostic Function (C000H to DFFFH). . . . 1871

CHAPTER 76 EVENT LIST 1887

76.1 How to Read the Event List . . . 1887
76.2 System (00000H to 03FFFH) . . . 1890
76.3 Security (10000H to 1FFFFH) . . . 1906
76.4 Operation (20000H to 2FFFFH). . . . 1907

CHAPTER 77 RESPONSE CODE (SDO ABORT CODE) 1912

CHAPTER 78 FTP SERVER FUNCTION REPLY LIST 1914

APPENDICES 1922

Appendix 1 External Dimensions **1922**
Appendix 2 EMC and Low Voltage Directives **1923**
Measures to comply with the EMC Directive 1923
Measures to comply with the Low Voltage Directive 1929
Appendix 3 General Safety Requirements **1930**
System design circuit examples 1930
Fail-safe measures for controller failure 1934
Appendix 4 Clock Data **1935**
Time setting 1935
SNTP client 1937
Setting time zone 1940
Daylight saving time function 1941
System clock 1944
Appendix 5 I/O Signals **1945**
List of input signals 1945
List of output signals 1945
Details of input signals 1946
Details of output signals 1948
Appendix 6 List of Special Relay (SM) Areas **1949**
Diagnostic information 1950
System information 1952
System clock 1953
Fixed scan function information 1955
Drive information 1956
Instruction related 1957
Latch area 1959
Data logging function 1961
Controller data backup/restoration function 1963
iQ Sensor Solution data backup/restoration function 1964
File transfer function (FTP client) 1966
Event history function 1966
User authentication function 1966
Ethernet function 1967
Add-on function 1967
Appendix 7 List of Special Register (SD) Areas **1968**
Diagnostic information 1969
System information 1986
System clock 1989
Fixed scan function information 1990
Drive information 1992
Instruction related 1994
Latch area 1996
Data logging function 1997
Controller data backup/restoration function 1999
Data backup/restoration function of iQ Sensor Solution 2002

Interrupt pointer mask pattern . . . 2005
Event history function . . . 2005
Program monitor function . . . 2006
User authentication function . . . 2006
Communication enable setting function . . . 2006
Real-time monitor function . . . 2006
FUNCTION LED indication function . . . 2007
Debug function . . . 2007
Ethernet function . . . 2008
Open completion signal function . . . 2010
Open request signal function . . . 2010
Socket communications receive status signal function . . . 2010
Data logging setting function . . . 2011
Label allocating information management function . . . 2012
Appendix 8 List of Link Special Relay (SB) . . . 2013
Appendix 9 List of Link Special Register (SW) . . . 2017
Appendix 10 Buffer Memory . . . 2028
List of buffer memory addresses . . . 2028
Details of buffer memory addresses (CPU function part) . . . 2041
Details of buffer memory addresses (CC-Link IE TSN function part) . . . 2062
Details of buffer memory addresses (motion function part) . . . 2076
Appendix 11 Parameter List . . . 2077
System parameters . . . 2077
CPU parameters . . . 2078
Module parameters . . . 2080
Memory card parameters . . . 2084
Appendix 12 Processing Time of CPU Function Part . . . 2085
Program execution time . . . 2085
END processing time . . . 2088
END processing extension time . . . 2096
Synchronous station refresh execution time . . . 2099
Execution time of data logging function . . . 2100
Controller data backup/restoration function execution time . . . 2105
Real-time monitor execution time . . . 2106
File operation execution time . . . 2107
Firmware update execution time . . . 2109
Appendix 13 CC-Link IE TSN Processing Time . . . 2110
Transmission delay time . . . 2110
Shortening method of the communication cycle interval and cyclic transmission time . . . 2116
Appendix 14 Ethernet Processing Time . . . 2117
Processing time of the simple CPU communication function . . . 2117
Processing time of the Web server function . . . 2119
Processing time of the OPC UA server function . . . 2120
Appendix 15 Service Processing . . . 2122
Target list and operation details of the device/label access service processing setting . . . 2122
Motion service processing . . . 2128
Appendix 16 Connection of CC-Link IE TSN Class B/A Devices . . . 2129
Configuration with CC-Link IE TSN Class B/A devices (Protocol version 2.0/1.0) . . . 2129
Configuration with CC-Link IE TSN Class B/A devices (Protocol version 1.0 only) . . . 2132
Appendix 17 Operation Image and Data Structure of Predefined Protocol . . . 2143
Operation image of each communication type of protocol . . . 2143

Verification operation of receive packet . . . 2148
Example of packet element data . . . 2149
Appendix 18 Connection to Servo Amplifier That Supports CC-Link IE TSN . . . 2152
MR-J5(W)-G (cyclic synchronous mode) connection method . . . 2152
MR-J5(W)-G (other than cyclic synchronous mode) connection method . . . 2161
MR-JET-G connection method . . . 2165
Relevant functions . . . 2165
Precautions . . . 2190
Appendix 19 Port Numbers Used by the System . . . 2191
Ports for CC-Link IE TSN . . . 2191

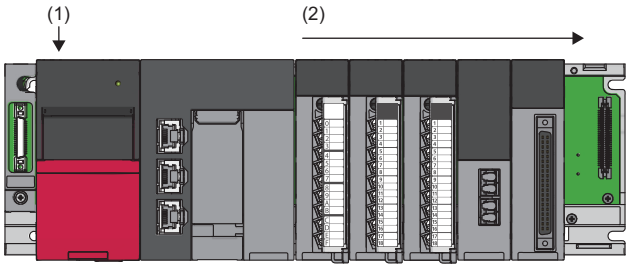
RELEVANT MANUALS

The following manuals and guidelines are relevant to this product.

Manuals



Manual name [Manual number]	Description
MELSEC MX Controller MX-R Model User's Manual [SH-082641ENG] (this manual)	Procedures before operation, specifications, devices, memory, functions, parameters, and troubleshooting of the controller
MELSEC MX Controller MX-R Model Programming Manual [SH-082644ENG]	Program language specifications, controller instructions, standard functions/function blocks, and specifications of motion control function blocks
GX Works3 Operating Manual [SH-081215ENG]	System configuration, parameter settings, and online operations of GX Works3
CPU Module Logging Configuration Tool Version 1 Operating Manual [SH-082478ENG]	System configuration and operation/setting procedures when using CPU Module Logging Configuration Tool
SLMP Reference Manual [SH-080956ENG]	A protocol used to access an SLMP-compatible device from an external device (such as a personal computer or HMI (Human Machine Interface)) or an SLMP-compatible module (such as the Ethernet-equipped module or modules on CC-Link IE TSN)
iQ Sensor Solution Reference Manual [SH-081133ENG]	Operation methods of the online functions for iQ Sensor Solution

Guidelines

Guideline name [Guideline number]	Description
FA SYSTEM SECURITY GUIDELINE -SEPARATE VOLUME [MELSEC]- [BCN-P5999-1474]	Mitsubishi Electric approach to security for the MELSEC series and information for using the MELSEC series safely and securely in an FA system

MELSEC iQ-R series manuals

Since the MELSEC MX Controller MX-R Model is used in combination with the MELSEC iQ-R series modules, refer to the MELSEC iQ-R series manuals.

(1) MELSEC iQ-R series main base unit and power supply module
(2) MELSEC iQ-R series intelligent function modules and I/O modules

Item		Reference manual
(1)	Base unit and power supply module	MELSEC iQ-R Module Configuration Manual [SH-081262ENG]
(2)	Procedures before operation, connections, functions, and troubleshooting of the intelligent function modules and I/O modules	User's manuals for the MELSEC iQ-R series modules
	Dedicated instructions for the intelligent function modules and I/O modules	MELSEC iQ-R Programming Manual (Module Dedicated Instructions) [SH-081976ENG]
	Module FBs for the intelligent function modules and I/O modules	Function block references for the MELSEC iQ-R series modules

TERMS

Unless otherwise specified, this manual uses the following terms.

Term	Description
Actual position	A position obtained by rounding a position address returned by a device with a ring counter. It is affected by a current position change.
Actual pressure	The actual value of pressure
Actual velocity	A value obtained by converting the actual value received from the device on the real axis to the unit of the axis
Axes group variable	An AXES_GROUP type variable instance including parameters and data related to the axes group
Axis	A target to perform the motion control
Axis variable	An AXIS_* type variable instance including parameters and data related to the axis
Axis warning	An error or a warning related to an axis
Basic core	A core that executes a program
Buffer memory	A memory to store data such as setting values and monitored values.
Buffering	Standby status of a motion control FB when multiple start is performed
Buffering FB	A motion control FB that is in a pending status (Busy is TRUE) when multiple start is performed
Cam table	An operation profile data used for cam control (Example) Operation profile data of cam data format or operation profile data of cam data format for rotary cutter
CC-Link IE TSN Class	A group of devices and switching hubs compatible with CC-Link IE TSN, ranked according to the functions and performance by the CC-Link Partner Association. For CC-Link IE TSN Class, refer to the CC-Link IE TSN Installation Manual (BAP-C3007ENG-001) published by the CC-Link Partner Association.
CC-Link IE TSN function part	A part used for Ethernet communications and CC-Link IE TSN communications through the CC-Link IE TSN port (P1, P2)
CC-Link IE TSN Protocol version 1.0	This protocol is used to perform communications by using the time sharing method defined by IEEE 802.1AS or IEEE 1588 for time synchronization.
CC-Link IE TSN Protocol version 2.0	This protocol is used to perform communications by using the time sharing method defined by IEEE 802.1AS and time-managed polling method for time synchronization. Supporting this protocol version mitigates restrictions when "Mixture of CC-Link IE TSN Class B/A or CC-Link IE TSN Class A Only" is set in the system configuration, and increases the number of connectable devices.
Command limit velocity	Set value for limit velocity
Command pressure	Set value for pressure
Commanded limit velocity	A specified value for limit velocity
Commanded position	A command position address that is specified in the motion FB
Commanded pressure	A specified value for pressure
Commanded velocity	Velocity that is specified in the motion FB
Continuous update	Continuous reflection of input values to the control while the ContinuousUpdate input of the motion control FB is TRUE
Core	An operation circuit of the controller. The controller has multiple cores.
CPU function part	A part used for sequence control and Ethernet communications through the Ethernet port (P3)
CPU Module Logging Configuration Tool	Software to configure data logging settings and to manage collected data
Cumulative current position	A command position address that is not rounded by the ring counter. It is affected by a current position change.
Cyclic data transfer processing	Processing of a cyclic transmission from its start to finish, performed by all the stations on a single network. The processing is performed asynchronously with the sequence scan of the CPU function part. The cyclic data transfer processing time varies depending on data volume and the number of transient transmission requests.
Dedicated instruction	An instruction that simplifies programming for using functions of intelligent function modules
Device	A memory of the controller to store data. Devices such as X, Y, M, and D are provided depending on the intended use.
Device station	A station other than a master station: a local station, a remote station
Disconnection	A process of stopping data link for relevant stations if a data link error occurs
Extension core	A core to which functions to be executed can be assigned
External signal high-accuracy input	An input signal linked with the signal detection time of the device station
FB instance	A function block that is inserted to a sequence program
First point of cam table	The meaning is different depending on the interpolation method specification for the cam data • Section interpolation or spline interpolation: Point of Table No.1 • Linear interpolation: Point of No.1

Term	Description
Forward-side position	Data to be sent to the drive unit as object data "Forward-side stop function (2E56H)". The limit position to which an axis can move in the pressure increase direction at feed/dwell, or the last position at pressure release.
Global label	A label that is valid for all the program data when multiple program data are created in the project. There are two types of global label: a module specific label (module label), which is generated automatically by GX Works3, and an optional label, which can be created for any specified device.
Grandmaster	A source device or station to synchronize clocks in the time synchronization via PTP (Precision Time Protocol)
GX LogViewer	Software to display data collected by data logging
GX Works3	The product name of the software package for the MELSEC programmable controllers
Industrial switch (CC-Link IE TSN certified)	A switching hub authorized by CC-Link Partner Association (☞ Page 63 Industrial switch)
Input variable	An input argument of FB
Intelligent function module	A module that has functions other than input and output, such as an A/D converter module and D/A converter module
iQSS	iQ Sensor Solution. Cooperation of sensors, programmable controllers, HMI (Human Machine Interface), and engineering tool to facilitate the start-up or maintenance of sensors. (📖iQ Sensor Solution Reference Manual)
Jerk	Chronological change rate of acceleration or deceleration
Label	A variable consisting of a specified string used in I/O data or internal processing
LB	A link relay of a link device. Bit data sent from each station of the network.
Link device	A device (RX, RY, RWr, RWw, LB, or LW) in the CC-Link IE TSN function part or a network module
Local station	A station that performs cyclic transmission and transient transmission with the master station and other local stations
LW	A link register of a link device. Word data (16-bit data) sent from each station of the network.
Machine feed value	A command position address that is not rounded by the ring counter. It is based on the home position, and it is not affected by a current position change.
Master axis (input) absolute coordinate	Another term for the Master axis absolute coordinate (MasterAbsolute) for input variables of MC_CamTableSelect (Cam Table Selection)
Master station	A station that controls the entire network. This station can perform cyclic transmission and transient transmission with all stations. Only one master station can be used in a network.
Module label	A label that represents one of memory areas (I/O signals and buffer memory areas) specific to each module in a given character string. For the module used, GX Works3 automatically generates this label, which can be used as a global label.
Motion control FB	An FB that is related to motion control. Its name starts with MC_ or MCv_.
Motion FB	A motion control FB that takes an axis or an axes group for the argument and changes the axis status or the axes group status when executed
Motion function part	A part of the controller used for motion control
Motion system	A system that realizes motion control constructed with the CPU function section, CC-Link IE TSN function section, and the motion function section of the controller
MR Configurator2	A product name of the servo setup software
Multicast filter	A filter function that selects whether to send cyclic data of multicast mode received by the own station to the subsequent stations. Setting parameters for this function are not required because the master station automatically sets the parameters according to the system configuration.
Multicast mode	A communication mode used to send cyclic data to multiple stations
Multiple axes interpolation control	Control in which multiple axes work together such as linear interpolation and circular interpolation. Axes to be cooperated are specified in an axes group.
Multiple start	Executing another motion control FB to the same axis to which the other motion control FB is being executed
Object	Data of a device compatible with CANopen
Output variable	An output argument of FB
POU	A unit that configures a program. Units are categorized and provided in accordance with functions. A program that is composed of POUs (program organization units) allows the lower-layer processing, when the program is multi-layered, to be divided into several units by processing and function, enabling the creation of programs based on each unit.
Predefined protocol support function	A function of GX Works3. This function sets protocols appropriate to each external device and reads/writes protocol setting data.
Program block	A group of POUs that configure a program
Real axis	An axis that is linked with a device on the network
Real drive axis	An axis that is linked with a CC-Link IE TSN compatible device that supports csp/csv/cst mode (sequential command) of the CiA402 drive profile

Term	Description
Real encoder axis	An axis that generates a commanded position from the current position of the encoder connected with a device. It is used as the master axis of the single axis synchronous control.
Reconnection	A process of restarting data link for relevant stations when the faulty station recovers from an error
Relay station	A station that relays data link to other station with mounting more than one network modules on one programmable controller.
Remote station	A station that exchanges I/O signals (bit data) and I/O data (word data) with another station by cyclic transmission. This station can perform transient transmission.
Reserved address	An IP address reserved for special purposes, defined by RFC 6890. This IP address cannot be used when the programmable controller is connected via the global IP network.
Routing	A process of selecting paths for communication with other networks. There are two types of routing: dynamic routing that auto-selects the communication routes, and static routing where communication routes are arbitrarily set.
RWr	A remote register of the link device. Word data (16-bit data) input from a device station to the master station. (For some areas in a local station, data are input in the opposite direction.)
RWw	A remote register of the link device. Word data (16-bit data) output from the master station to a device station. (For some areas in a local station, data are output in the opposite direction.)
RX	Remote input of the link device. Bit data input from a device station to the master station. (For some areas in a local station, data are input in the opposite direction.)
RY	Remote output of the link device. Bit data output from the master station to a device station. (For some areas in a local station, data are output in the opposite direction.)
SB	An abbreviation for a link special relay. Bit data that indicates the operating status and data link status of a module on CC-Link IE.
Set position	A commanded position address rounded by the ring counter. It is affected by a current position change.
Set velocity	The current control value that is generated by motion operation
Signal flow	The execution status that the last time an operation of a program or an FB is executed in each step.
Single axis synchronization	A control to output the position information (command) of one Slave (slave axis) that is synchronized with Master (master axis)
Slave axis (output) absolute coordinate	Another term for the Slave axis absolute coordinate (SlaveAbsolute) for input variables of MC_CamTableSelect (Cam Table Selection)
SLMP	A SeamLess Message Protocol. This protocol is used to access an SLMP-compatible device or a programmable controller connected to an SLMP-compatible device from an external device.
Soft LED	An LED that is not mounted as the hardware, but is controlled by software only Check by using the module diagnostics.
SW	An abbreviation for a link special register. Word data that indicates the operating status and data link status of a module on CC-Link IE.
Switching speed	• The set velocity of the on-going motion control FB when Aborting is specified • The command velocity when the on-going motion control FB reached the target position when Blending is specified
System error	An error or a warning not related to an axis. When Axis information (Axis) and Axes Group Information (AxesGroup) of the motion control FBs are not correct, the system error will occur.
Target position	A command position address that is specified in the motion FB
Transient transmission group number	Number that is assigned for transient transmission to any given stations. By specifying a group of stations as transient transmission target, data can be sent to the stations of the same group No.
TSN hub	Notation of industrial switches (CC-Link IE TSN Class B certified) on an engineering tool
Unicast mode	A communication mode used to send cyclic data to one station
Virtual axis	An axis that is not linked with a device on network
Virtual drive axis	A virtual axis that can generate a command virtually
Virtual encoder axis	An axis that generates a commanded position from a variable. It is used as the master axis of the single axis synchronous control.
Virtual linked axis	An axis that connects FBs and transmits commands in the single axis synchronous control

GENERIC TERMS AND ABBREVIATIONS

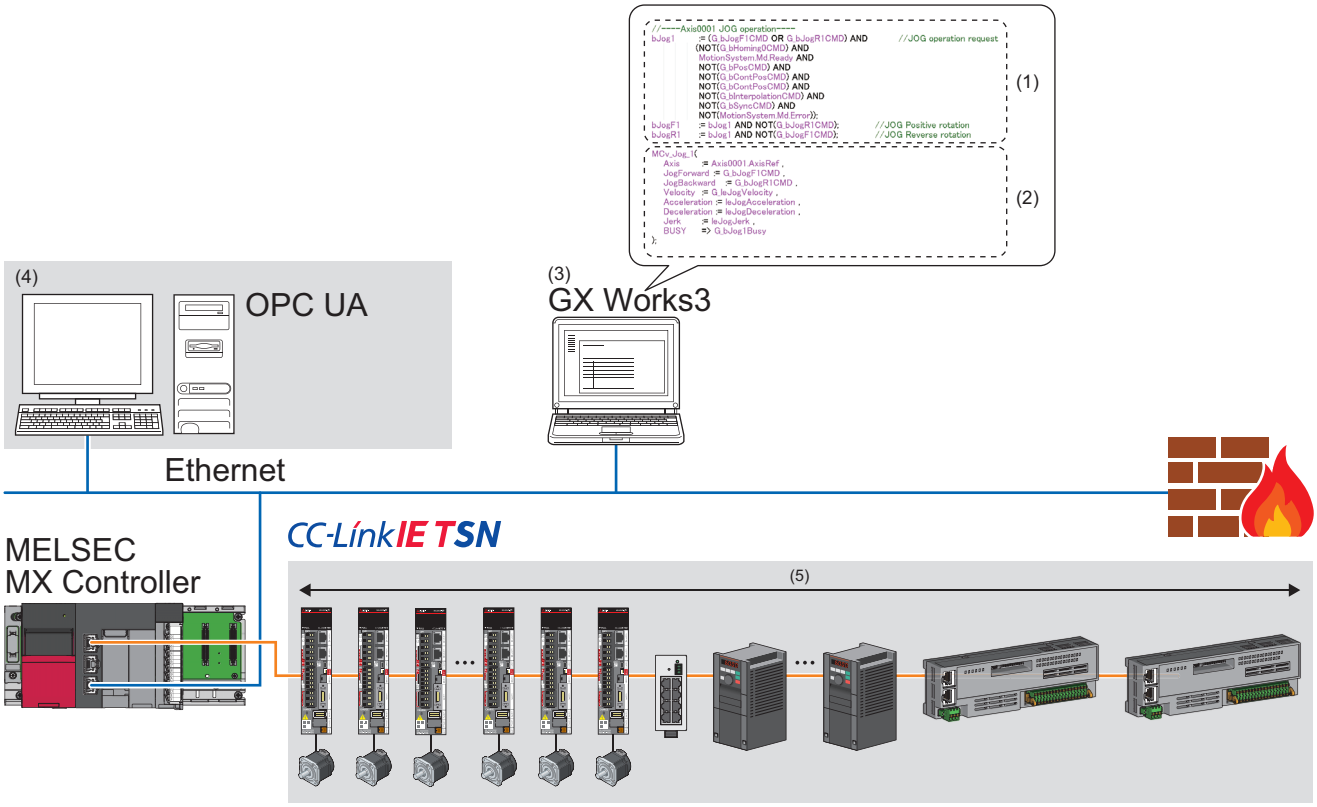
Unless otherwise specified, this manual uses the following generic terms and abbreviations.

Generic term/abbreviation	Description
Base unit	A generic term for main base units and extension base units
CC-Link IE	A generic term for the following items: • CC-Link IE TSN • CC-Link IE Controller Network (MELSEC iQ-R CC-Link IE Controller Network User's Manual (Application)) • CC-Link IE Field Network (MELSEC iQ-R CC-Link IE Field Network User's Manual (Application))
CC-Link IE Controller Network-equipped module	An RJ71GP21-SX CC-Link IE Controller Network module, an RJ71GP21S-SX CC-Link IE Controller Network module, and the following modules when the CC-Link IE Controller Network function is used: • RJ71EN71
CC-Link IE TSN master/local module	RJ71GN11-T2, RJ71GN11-SX, RJ71GN11-EIP (CC-Link IE TSN part)
CC-Link IE TSN-equipped module	A generic term for the RJ71GN11-T2, RJ71GN11-SX, and RJ71GN11-EIP
Controller	A generic term for the MXR300-16, MXR300-32, MXR300-64, MXR500-128, and MXR500-256
csp	An abbreviation for cyclic synchronous position mode (one of the control modes on the drive unit side)
cspr	An abbreviation for cyclic synchronous pressure mode (one of the control modes on the drive unit side)
cst	An abbreviation for cyclic synchronous torque mode (one of the control modes on the drive unit side)
csv	An abbreviation for cyclic synchronous velocity mode (one of the control modes on the drive unit side)
ct	An abbreviation for continuous operation to torque control mode (one of the control modes on the drive unit side)
Data link	A generic term for cyclic transmission and transient transmission
Device supporting iQSS	A device which supports iQ Sensor Solution. iQ Sensor Solution Reference Manual
Drive unit	A generic term for motor drive devices such as a servo amplifier
Engineering tool	A tool used for setting up controllers or servo amplifiers, programming, debugging, and maintenance
Ethernet device	A generic term for the devices supporting IP communication (such as a personal computer, a vision sensor, and a bar code reader)
Ethernet-equipped module	A generic term for the following modules: • Controller (when the Ethernet function is used) • RJ71EN71 (when the Ethernet function is used)
GOT	A generic term for Mitsubishi Electric Graphic Operation Terminal GOT1000 and GOT2000 series
hm	An abbreviation for homing mode (one of the control modes on the drive unit side)
I/O module	An input module, an output module, an I/O combined module, and an interrupt module
ICMP	An abbreviation for Internet Control Message Protocol. This protocol is used to exchange messages of errors in an IP network or other information related to an Ethernet network.
MCFB	An abbreviation for motion control FB
MR-J5(W)-G	A generic term for the MR-J5-_G/MR-J5-_G_-RJ/MR-J5-_G_-LL/MR-J5W_-_G/MR-J5D_-_G_ model servo amplifiers
Operation profile data	A generic term for waveform data used for each control
PDO	An abbreviation for Process Data Object. Aggregation of application objects transferred periodically between multiple CANopen nodes.
Power supply module	A MELSEC iQ-R series power supply module
PTP	An abbreviation for Precision Time Protocol. A predefined protocol for time synchronization between devices on a network.
RJ71GN11	A generic term for the RJ71GN11-T2 and RJ71GN11-SX
SDO	An abbreviation for Service Data Object. A message to access an object entry in the object dictionary of a CANopen node. Data is sent/received between the stations aperiodically.
SLMP	An abbreviation for Seamless Message Protocol. This protocol is used to access an SLMP-compatible device from an external device (such as a personal computer or HMI (Human Machine Interface)) or an SLMP-compatible module (such as the Ethernet-equipped module or modules on CC-Link IE TSN).
Station sub ID number	An ID number of a sensor connected to a CC-Link-compatible communication module

MEMO

PART 1 OVERVIEW

This part consists of the following chapter.



1 MELSEC MX CONTROLLER

1 MELSEC MX CONTROLLER

A MELSEC MX Controller (referred to as the controller in this manual) can achieve the following:

Integration of sequence control, motion control, and network

A system with a network that can execute the sequence control and motion control by a single controller can be constructed.

(1) Sequence control program
(2) Motion control program
(3) Engineering tool
(4) Upper system
(5) Up to 256 axes used for motion control (with multi-axis servo amplifiers)/Up to 253 device stations connected

■Controlling the entire line by a single controller

- Servo amplifiers, inverters, and remote I/O modules can be connected on CC-Link IE TSN.
- The controller can be connected to CC-Link IE TSN and Ethernet simultaneously using three LAN ports.
- Data sharing and linking with the upper system can be performed with OPC UA communications.

■Improving efficiency by a single tool

- Sequence control and motion control can be set and programmed with a single tool.
- The primary judgment at an occurrence of trouble can be quickly determined using each monitor or diagnostic window.

■Protecting information assets by security measures

- The controller complies with the international standard IEC 62443-4-2.
- User authentication and communication encryption can prevent data leakage and unauthorized access.
- Data tampering is detected, and the execution of unauthorized programs is prevented.

Point

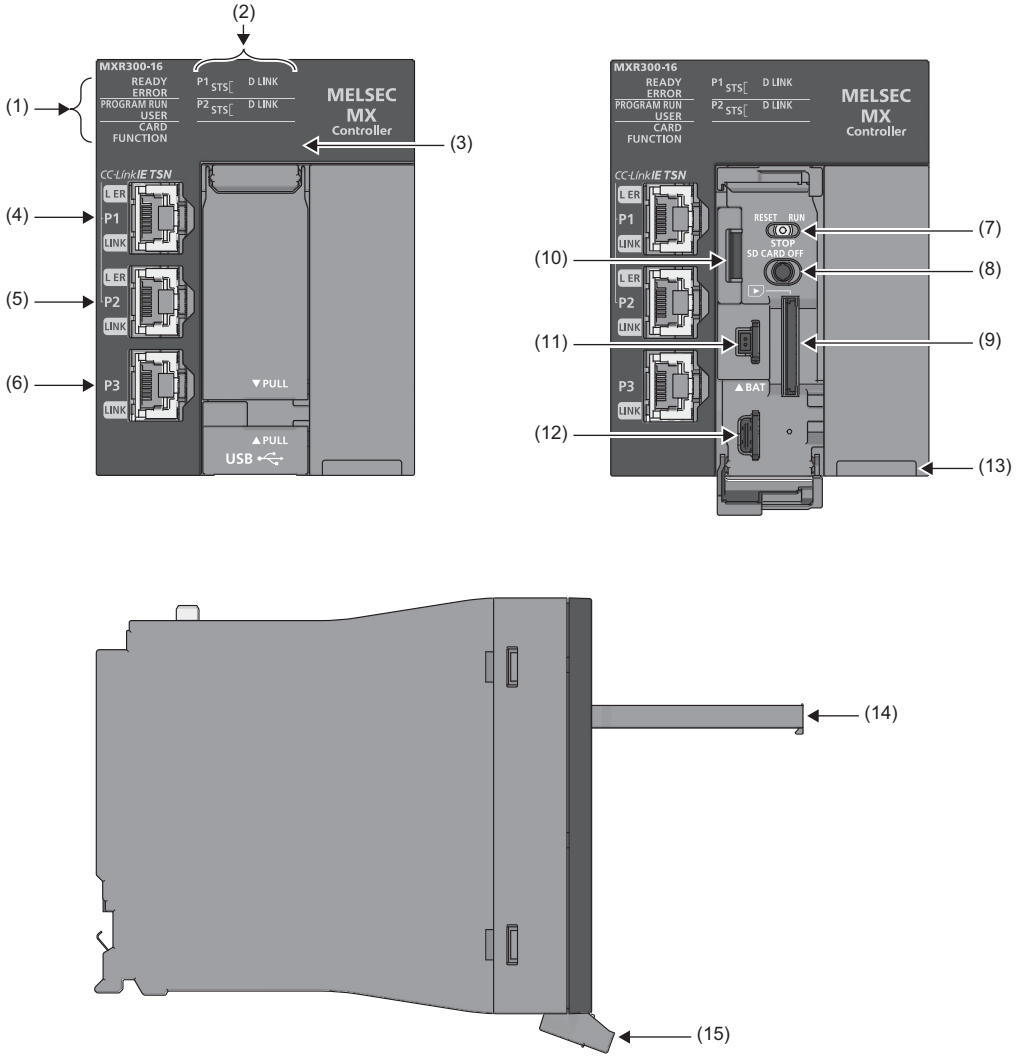
For the pages described in this manual, refer to the following.

☞ Page 11 Structure of this manual

MEMO

MEMO

PART 2 PART NAMES



This part consists of the following chapter.

2 CONTROLLER

2 CONTROLLER

This chapter describes the part names of the controller.

2.1 MX-R Model

No.	Name	Description
(1)	READY LED	Indicates the operating status of the hardware and the error level. (☞ Page 1674 Troubleshooting with LED Indicators) ● READY LED—ERROR LED status • On—off: Normal operation • On—on: Minor error • On—flashing: Moderate error • Flashing (every 1s)—off: Initial processing • Flashing (every 200ms)—on/flashing/off: All information initialization in progress • Off—on/flashing: Major error
	ERROR LED	
	PROGRAM RUN LED	Indicates the operating status of the program. • On: Being executed (RUN state) • Flashing: Being suspended (PAUSE state) • Off: Stopped (STOP state) or stop error
	USER LED	Indicates the status of the annunciator (F). (☞ Page 351 Annunciator (F)) • On: Annunciator ON
	CARD LED	Indicates the status of the SD memory card. • On: SD memory card available • Flashing (every 50ms): Accessing the SD memory card • Slow flashing (every 200ms): Preparing the SD memory card • Off: Card not inserted or can be removed
	FUNCTION LED	Indicates the program restoration information write status. • Flashing: Program restoration information not written
(2)	STS LED	The LED is always off.
	D LINK LED	Indicates the data link status of P1 and P2. The D LINK LED of P2 is always off. • On: Cyclic transmission being performed • Flashing: Cyclic transmission stopped • Off: Disconnected
(3)	Dot matrix LED	Displays the station number set for the controller. Parameter not set: "— — —" Master station: 0 ■When a data link faulty station is detected, or when an error is detected in all stations The station number and ERR are displayed in alternating repetition. ■At error detection Displays S-ERR and the error number. ■In module communication test mode Displays the module communication test result. (☞ Page 1769 Module communication test)
(4)	P1	Port for CC-Link IE TSN. Connect an Ethernet cable. For wiring methods and wiring precautions, refer to the following. (☞ Page 64 Ethernet cable wiring method)
	L ER LED	Indicates the port status. • On: Abnormal data received • Off: Normal data received
	LINK LED	Indicates the link status. • On: Link-up • Flashing: Data being sent or received • Off: Link-down
(5)	P2	Same as P1
	L ER LED	
	LINK LED	
(6)	P3	Port for Ethernet. Connect an Ethernet cable. For wiring methods and wiring precautions, refer to the following. (☞ Page 64 Ethernet cable wiring method)
	LINK LED	Same as P1
(7)	RUN/STOP/RESET switch	A switch for controlling the operating status of the controller • RUN: Executes the program. • STOP: Stops the program. • RESET: Resets the controller. (Keep the switch in the RESET position for approximately one second.) Operate the RUN/STOP/RESET switch with your fingers. To prevent the switch from being damaged, do not use any tool such as a screwdriver.
(8)	SD CARD OFF button	A switch for stopping card access when the SD memory card is removed (☞ Page 57 SD memory card removal procedure)
(9)	SD memory card slot	A slot where an SD memory card is inserted
(10)	Battery compartment	A compartment for storing the body of the battery (FX3U-32BL) when the battery is connected

No.	Name	Description
(11)	Battery connector	A connector for connecting to the battery (FX3U-32BL)
(12)	USB port*1	A port for connecting to a USB-compatible device (Connector type: Type-C)
(13)	Serial number marking	Indicates the serial number (16 digits) of the module.
(14)	Switch cover	A cover for the switch. Open this cover and set the switch. Otherwise, keep the cover closed to prevent entry of foreign matter such as dust.
(15)	USB cover	A cover for the USB port. When not using the USB port, keep the cover closed to prevent entry of foreign matter such as dust.

*1 When a cable is connected to the USB port at all times, clamp the cable to prevent a poor connection, moving, and disconnection by unintentional pulling.

PART 3 PROCEDURES BEFORE OPERATION

This part consists of the following chapters.

3 START-UP PROCEDURE

4 CONNECTION BETWEEN THE PERSONAL COMPUTER AND CONTROLLER

5 PARAMETER SETTINGS

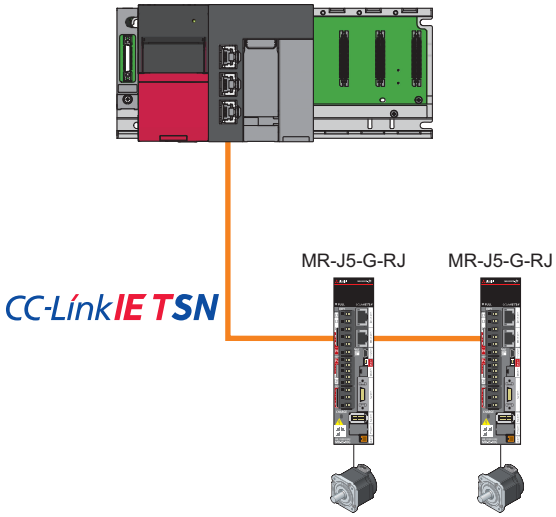
6 PROGRAM EXAMPLES

3 START-UP PROCEDURE

This chapter describes the procedures before operation.

Procedure	Description
1. Installing a battery	Install a battery to the controller.*1 ☞ Page 56 Battery installation procedure
2. Inserting an SD memory card	Insert an SD memory card to the controller as needed. ☞ Page 57 SD memory card installation procedure
3. Mounting modules and connecting cables	Mount the controller on the base unit, and connect cables. ☞ Page 58 Controller installation procedure
4. Powering on the system	Check the following before powering on the system. • A cable is correctly connected to the power supply. • Power supply voltage is within the specified range. • The controller is in the STOP state. • The controller is connected to a personal computer on which the engineering tool has been installed.
5. Starting up the engineering tool	Start up the engineering tool that has been installed on the personal computer connected to the controller.
6. Registering user information (user authentication function)	Register a user name and password used to log in to the project. Then, write the user information to the controller. 📖 GX Works3 Operating Manual
7. Initializing the controller	Initialize the controller using the engineering tool. ☞ Page 70 Initializing the controller
8. Setting parameters	Set parameters using the engineering tool. ☞ Page 71 PARAMETER SETTINGS
9. Creating programs	Create a program using the engineering tool. ☞ Page 97 PROGRAM EXAMPLES
10. Writing to the controller	Write the parameters set and the program created by using the engineering tool to the controller. ☞ Page 111 Conversion and writing of programs
11. Resetting the controller	Restart the system in either of the following ways. • Power off and on the system. • Reset the controller.
12. Checking for errors	Check the status of the READY LED and ERROR LED of the controller. If an error is detected, identify the error using the engineering tool, and eliminate the error cause. ☞ Page 1674 Troubleshooting with LED Indicators
13. Network diagnostics	Using network diagnostics, check if the cables are connected properly and communications are performed normally with the parameters. ☞ Page 1697 Checking the Network Status
14. Parameter setting of a device station	Set parameters of the device station used. 📖Manual for the device station used
15. Test operation	Check whether the created program was executed properly.
16. Executing the program	Set the controller to the RUN state and check that the PROGRAM RUN LED turns on.
17. Monitoring the program	Check that the program operates normally using the engineering tool. ☞ Page 113 Program monitor

*1 The controller does not need a battery for holding data. Use the battery (FX3U-32BL) to save clock data in the event of a long-term (10 days or more) power failure.



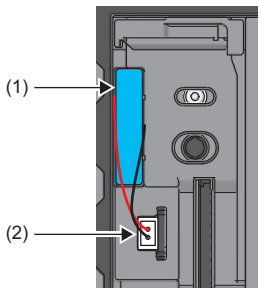
Precautions

When multiple device stations are powered on simultaneously, the startup time of the device stations may vary. In such a case, the networks are connected in turn, resulting in the possibility of the longer time to complete data links at all stations. Starting up the master station after all device stations have started prevents the time required for data links at all stations from increasing.

3.1 Connection Example

A connection example using the following devices is shown.

- Main base unit: R35B
- Power supply module: R61P
- Controller: MXR500-256
- Servo amplifier: MR-J5-G-RJ
- Servo motor (HK-KT series)



3.2 Mounting the Controller

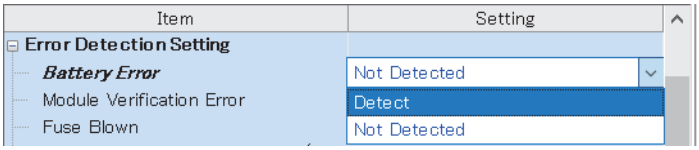
Installing a battery

Battery installation procedure

To use the battery, connect the battery, following the procedure below.

1. Open the switch cover on the front of the controller.
2. Connect the lead connectors to the battery connector (2) in the right orientation. Insert the battery in the battery compartment (1).
3. Close the switch cover on the front of the controller.

Point



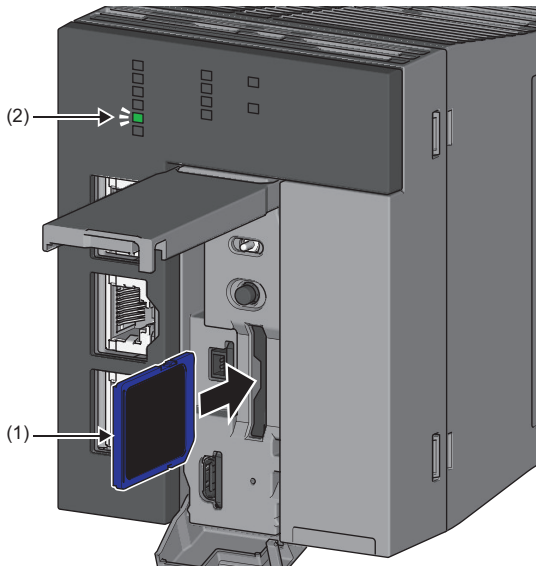
For the battery replacement procedure, refer to the following.

☞ Page 1621 Battery Replacement Procedure

■Battery error detection setting in the engineering tool

The following setting is required to use the battery.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [RAS Setting] ⇨ [Error Detection Setting] ⇨ [Battery Error]



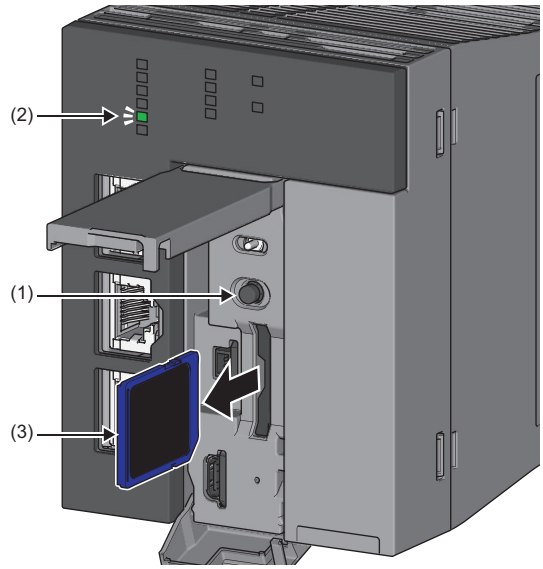
The default is "Not Detected", so change it to "Detect".

Inserting and removing an SD memory card

Insert an SD memory card to the controller as needed.

SD memory card installation procedure

Check the direction and insert an SD memory card, following the procedure below.



1. Insert an SD memory card (1) into the card slot until it clicks with the notched edge in the direction as illustrated. After inserting the card, check that it is inserted completely. Poor contact may cause malfunction.
2. The CARD LED (2) flashes until the SD memory card can be used. When the CARD LED is on, the SD memory card can be used.

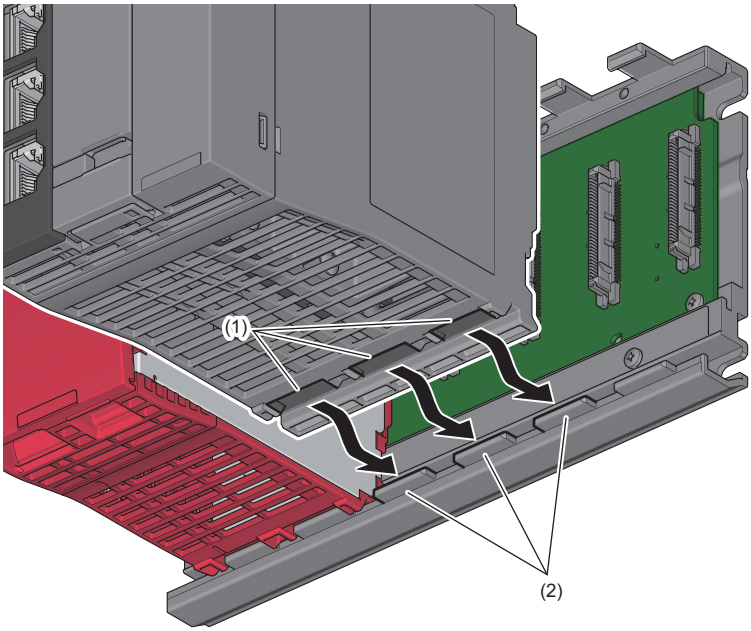
Point

If the CARD LED does not turn on even after the card is inserted, use the engineering tool to check that SM606 (SD memory card forced disable instruction) and SM607 (SD memory card forced disable status flag) are off.

SD memory card removal procedure

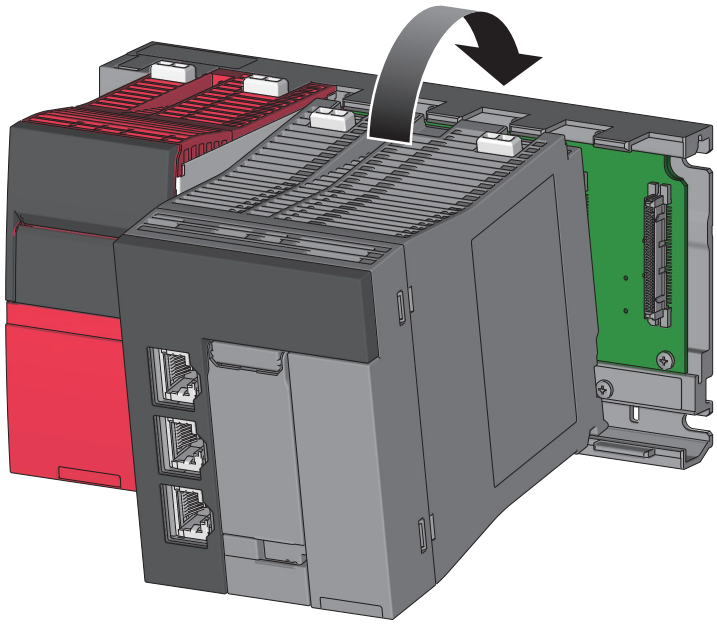
1. Press the SD CARD OFF button (1) for one second or longer to disable access to the SD memory card.*1
2. The CARD LED (2) flashes during the access stop processing, and turns off upon completion of the processing.
3. Push in and release the SD memory card (3), and then pull the card out of the slot.

*1 SM606 (SD memory card forced disable instruction) can also disable access to an SD memory card. For details, refer to the following.
☞ Page 324 How to forcibly disable the SD memory card with a special relay



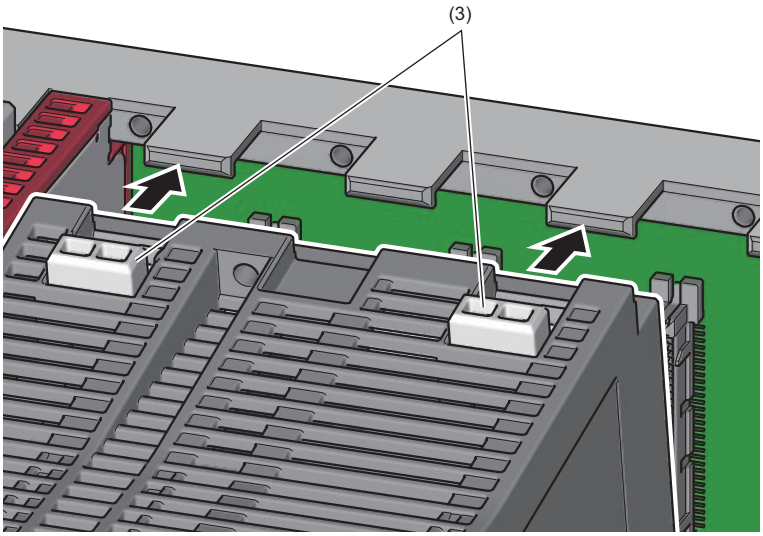
Precautions

- Do not drop or apply strong shock to the controller and SD memory cards.
- Follow the procedure above when inserting or removing the SD memory card while the system is powered on. If not, the data on the SD memory card may corrupt.
- If any function that accesses the SD memory card is being executed when removing the card, the CARD LED turns off after the processing of the function is completed. For this reason, the time required from when the CARD LED flashes slowly until when it turns off differs depending on the function being executed.
- If SM605 (Memory card remove/insert prohibit flag) is on, the CARD LED does not turn off even if the SD CARD OFF button is pressed. If not, turn on SM606 (SD memory card forced disable instruction) to forcibly disable the card.



Mounting/removing the controller on/from a main base unit

This section describes the procedure for mounting/removing the controller on/from the main base unit.
Power off a system when mounting/removing the controller. Attach a blank cover module (RG60) to each connector where no controller is mounted to prevent entry of foreign matter such as dust.



Controller installation procedure

1. If a cap is attached to the module connector of the base unit, remove it.
2. Place the concave part (1) of the controller onto the guide (2) of the base unit.

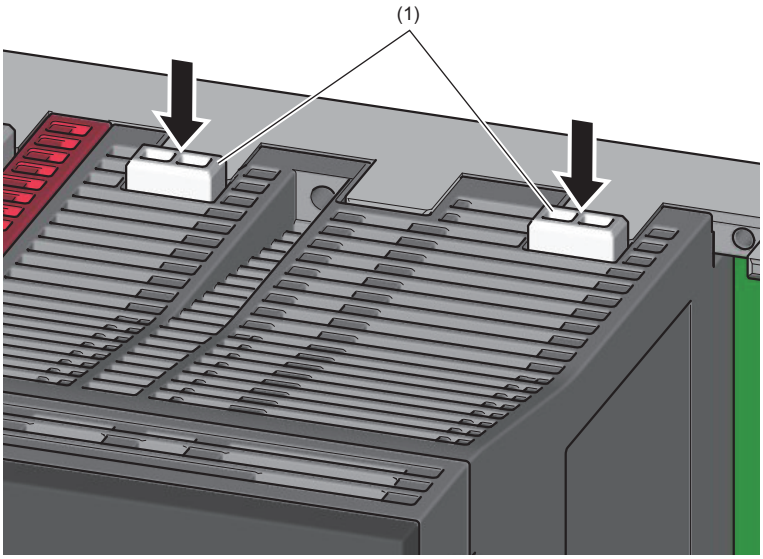
3. Using the guide (2) as a pivot point, push in the controller until the module fixing hook (3) snaps into place.
4. Check that the controller's module fixing hook (3) hangs the base unit and the controller is mounted on the base unit securely.

Point

When using the controller in environments in which it is subject to strong vibrations and shocks, take the following measures:

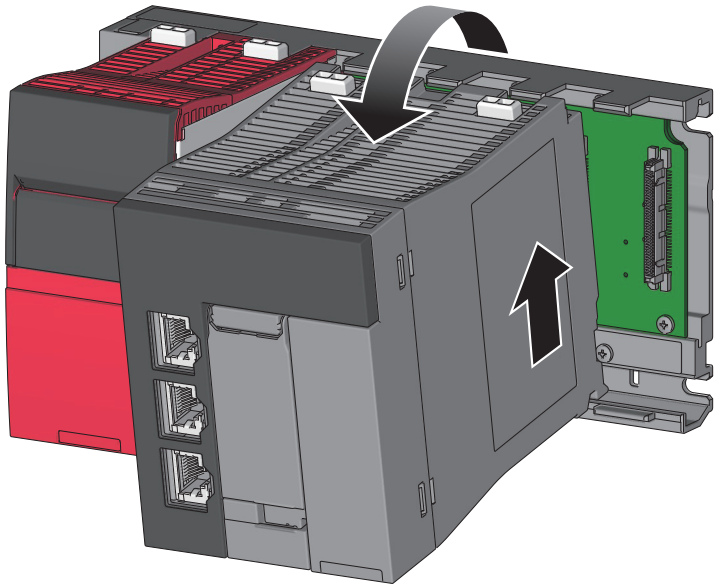
- Fix the controller to the base unit using screws. (Module fixing screw: M3×12 (sold separately))
- Place the cables connected to the controller in a duct or clump them to prevent the weight of the cables from putting stress on the controller.

■Precautions for installation



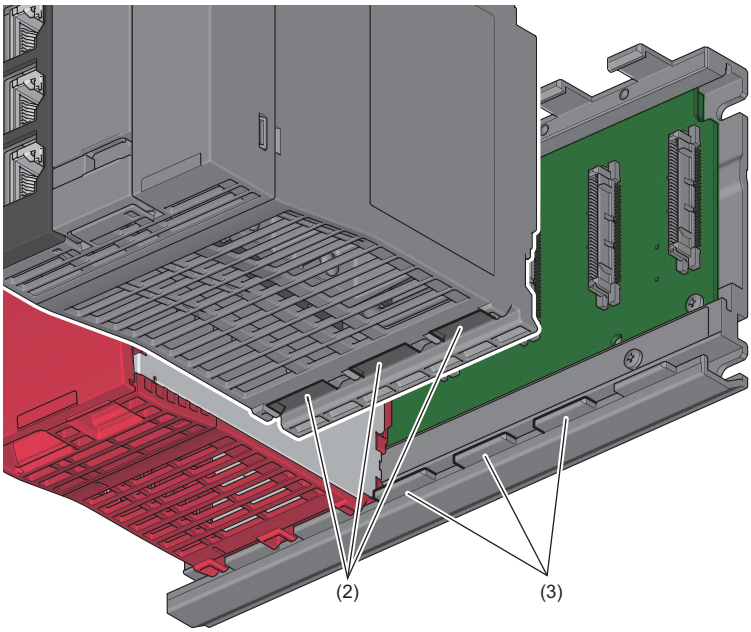
- Correctly place the concave part of the controller onto the guide of a base unit before mounting the controller. Failure to do so may damage the controller.
- When mounting the controller on the base unit in the control panel, keep a certain distance from the control panel for installation. For information on the installation position when a controller is used and the side dimensions for installation on the DIN rail, refer to the following.

Safety Guidelines (IB-0800726)



- When installing devices other than the controller, refer to the following.

MELSEC iQ-R Module Configuration Manual



Controller removal procedure

1. Support the controller with both hands and firmly press the module fixing hooks (1) on the top of the controller with your fingers.

2. Pull the controller straight while pressing the module fixing hooks (1), using the bottom of the controller as a fulcrum.
3. While lifting the controller, remove its concave part (2) from the guide (3) of the base unit.

Point

- When module fixing screws are used, remove the screws first and then the controller. Failure to do so may damage the controller.
- The controller surface temperature may be high immediately after power-off. When the controller is removed, pay attention to the burn injury.

3.3 Wiring

This section describes wiring products, wiring methods, and wiring precautions.

Wiring products

The following describes the devices used for the network.

Ethernet cable

Use an Ethernet cable that meets the following standards.

Communication speed	Ethernet cable	Connector	Type
1Gbps	Category 5e or higher, straight cable (shielded, STP)	RJ45 connector	The following conditioning cables: • IEEE 802.3 (1000BASE-T) • ANSI/TIA/EIA-568-B (Category 5e)
100Mbps	Category 5 or higher, straight cable (shielded, STP)		The following conditioning cables: • IEEE 802.3 (100BASE-TX) • ANSI/TIA/EIA-568-B (Category 5)

Cables for CC-Link IE TSN are available from Mitsubishi Electric System & Service Co., Ltd. (Catalogs for cable are also available.)
In addition, the connector processing of cable length is available for your preference. Please contact your local Mitsubishi representative.

Communication speed	Type	Model (Manufacturer)
1Gbps	Category 5e or higher, straight cable (double shielded, STP)	SC-E5EW series (Mitsubishi Electric System & Service Co., Ltd.)

Point

A communication error may occur due to high-frequency noise from other devices in a given connection environment.
The following are the measures to be taken with the wiring to avoid high-frequency noise influence.
- Use a duplex shield type cable.
- Do not bundle the cable with the main circuit or power cable or do not place it near those lines.
- Place the cable in a duct.

■Hubs

Use hubs that support the transmission speed of communication for use in the Ethernet.

Point

The controller determines whether to use 1000BASE-T/100BASE-TX and the full-duplex/half-duplex communication mode based on the hub. For connection to the hub with no auto-negotiation function, set the half-duplex communication mode on the hub side.

USB cable

Wire with a USB cable whose connector type is Type-C.

Industrial switch

Use the following industrial switches when using CC-Link IE TSN.

- Industrial switch (CC-Link IE TSN Class B certified)*1
- Industrial switch (CC-Link IE TSN Class A certified)

Point

- For the models and usage methods of the industrial switch, refer to the CC-Link Partner Association website (www.cc-link.org).
- Industrial switches can be used for cascade connection, but check the specifications of the industrial switch used.

*1 For the industrial switch (CC-Link IE TSN Class B certified), the NZ2MHG-TSNT☐ (Mitsubishi Electric Corporation) is recommended.

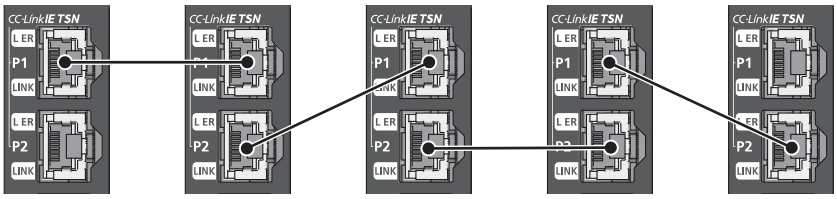
Precautions

Since there are different restrictions for a system configuration using industrial switch (CC-Link IE TSN Class B certified) and for a system configuration using industrial switch (CC-Link IE TSN Class A certified), setting with the engineering tool is required. (☞ Page 142 CC-Link IE TSN SYSTEM CONFIGURATION)

Ethernet cable wiring method

The following describes connection and disconnection of the Ethernet cable.

Installation method



1. Push the Ethernet cable connector into the controller until it clicks. Pay attention to the direction of the connector.
2. Lightly pull it to check that it is securely connected.
3. Check that the LINK LED of the Ethernet port where the Ethernet cable is connected is on.*1

*1 The time between the Ethernet cable connection and the LINK LED turning on may vary. The LINK LED usually turns on in a few seconds. Note, however, that the time may be extended further if the link-up processing is repeated depending on the status of the device on the line. If the LINK LED does not turn on, refer to the following and take corrective actions.
☞ Page 1678 When the LINK LED turns off

Point

CC-Link IE TSN devices can be connected to both P1 and P2.

- When only one port is used in a star topology, either P1 or P2 is applicable.
- When both ports are used in a line topology, P1-P1, P2-P2, and P1-P2 are acceptable.

Disconnecting the cable

1. Press the latch down and unplug the Ethernet cable.

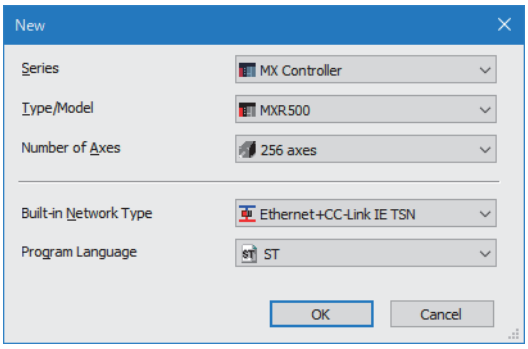
Precautions

Be sure to follow the precautions for wiring. Otherwise, some functions may not operate normally. (It may operate normally temporarily.)

- Place the Ethernet cable in a duct or clamp them. If not, dangling cable may swing or inadvertently be pulled, resulting in damage to the module or cables or malfunction due to poor contact.
- Do not touch the core of the cable-side or module-side connector, and protect it from dirt or dust. If oil from your hand, dirt or dust is attached to the core, it can increase transmission loss, arising a problem in a data link.
- Check that the Ethernet cable is not disconnected or not shorted and there is no problem with the connector connection.
- Before connecting the Ethernet cables, check also the CC-Link IE TSN Installation Manual available on the CC-Link Partner Association website (www.cc-link.org). Failure to follow the instructions in the manual may cause malfunctions.
- Do not use Ethernet cables with broken latches. Doing so may cause the cable to unplug or malfunction.
- Hold the connector part when connecting and disconnecting the Ethernet cable. Pulling the cable connected to the module may result in damage to the module or cables or malfunction due to poor contact.
- For connectors without an Ethernet cable, the attached connector cover should be placed to prevent foreign matter such as dirt or dust and to prevent failure or malfunction caused by static electricity.
- The maximum station-to-station distance of the Ethernet cable is 100m. However, the distance may be shorter depending on the operating environment of the cable. For details, contact the manufacturer of the cable used.
- The bending radius of the Ethernet cable is limited. For details, check the specifications of the Ethernet cable to be used.
- In a line topology, do not connect the device station with no IP address setting between the master station and device stations, or between device stations. A data link may not be established with the device stations connected from the device station with no IP address setting onwards. However, if the device station with no IP address setting is connected at the end of the line topology, the device stations between the master station and the device station at the end perform a data link.
- Communication with the Ethernet device may not be possible depending on the specifications of the connected Ethernet device or industrial switch. If communication is not possible, reduce the communication data volume of the Ethernet device.
- When setting "Communication Speed" of the master station to 100Mbps to connect a device with a communication speed of 100Mbps, enable auto-negotiation of the device.

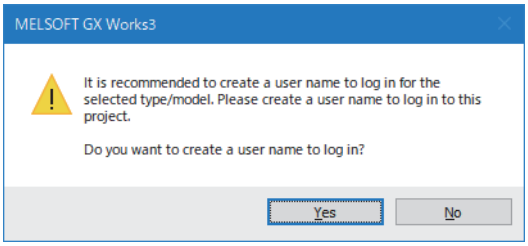
4 CONNECTION BETWEEN THE PERSONAL COMPUTER AND CONTROLLER

4.1 Engineering Tool Setting



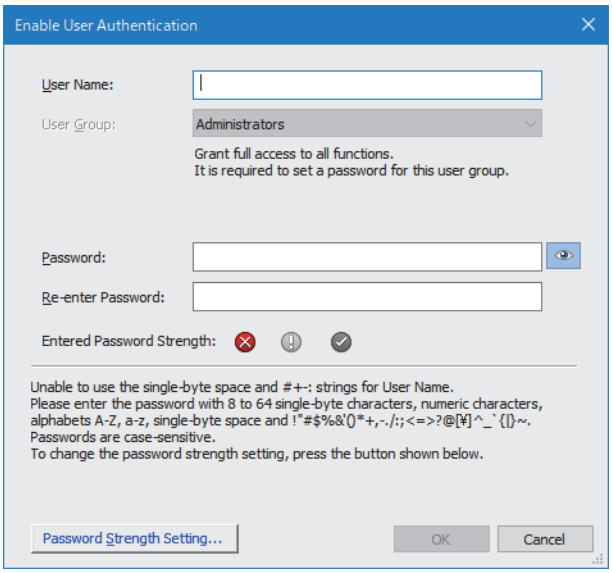
Creating a project

Create a new project.



Operating procedure

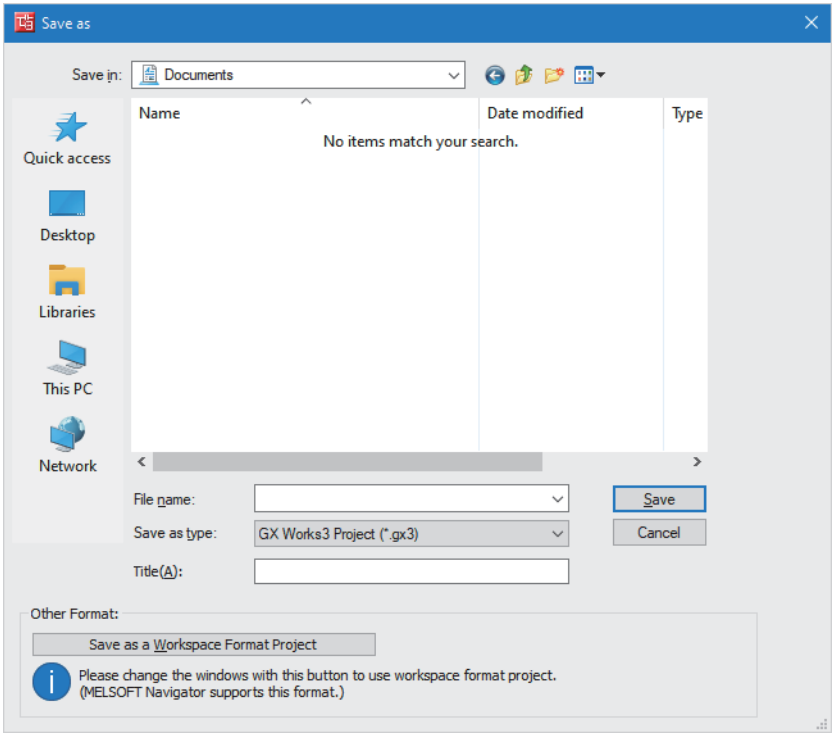
1. Start the engineering tool.
2. Set the controller as follows.



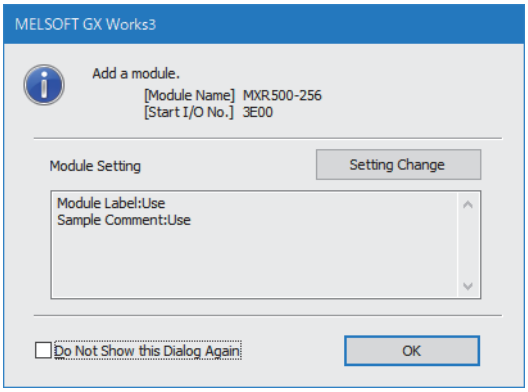
[Project] ⇨ [New]

3. Click the [Yes] button.

4. Configure each item and click the [OK] button.



Point

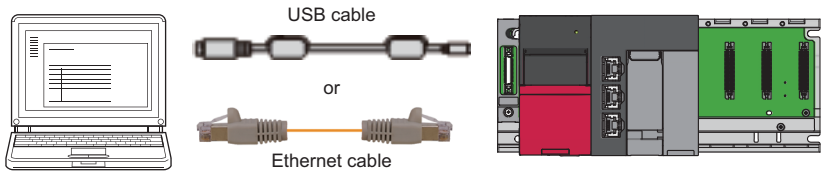


For details on characters that can be used in passwords, refer to the following.

☞ Page 2192 Password Policy

5. Configure each item and click the [Save] button.

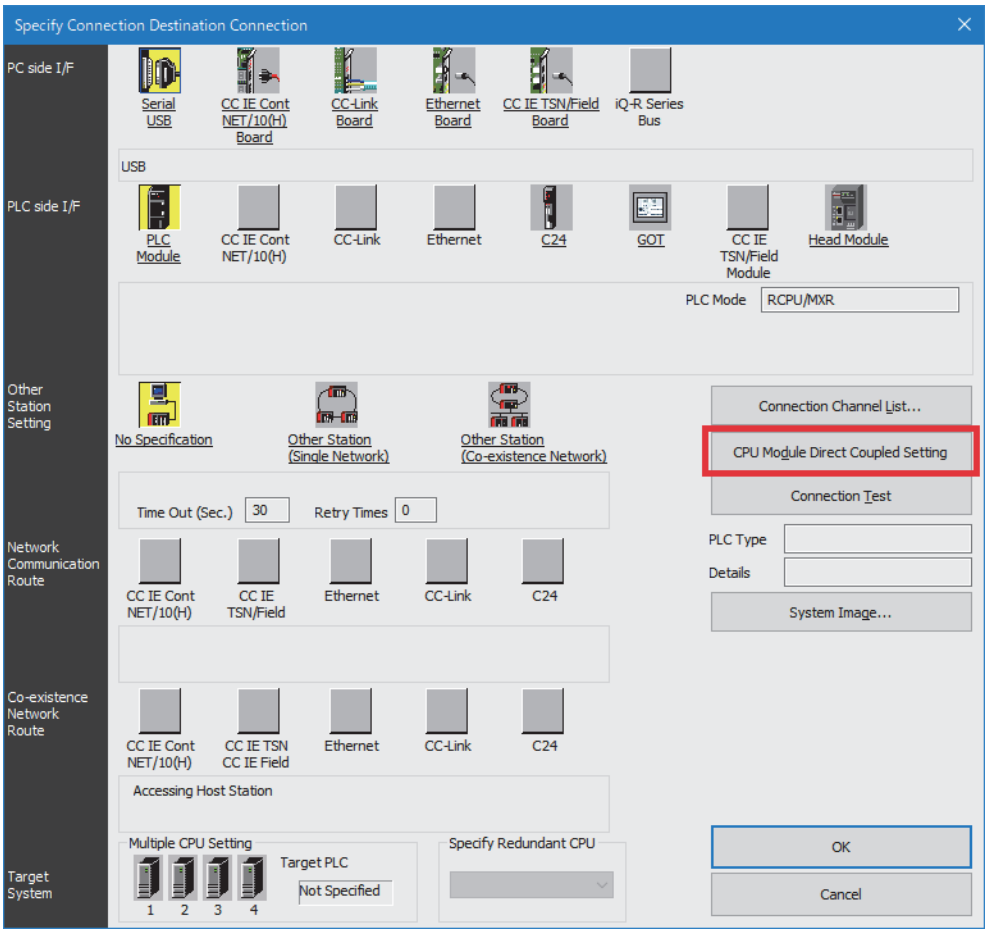
6. Click the [Setting Change] button and set "Module Label" to "Use".



7. Click the [OK] button to create the project.

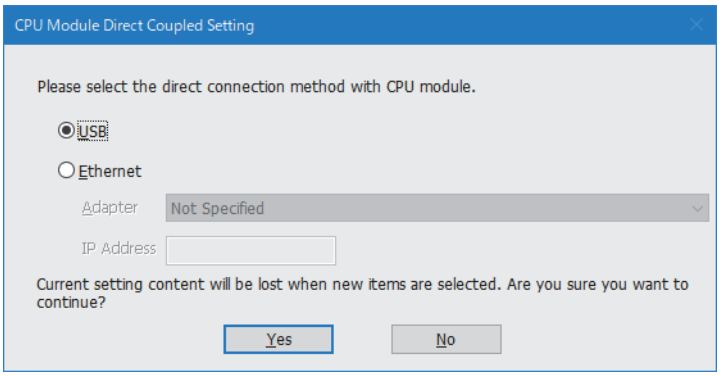
Connection between the personal computer and controller

Check the connection between the personal computer and the controller.

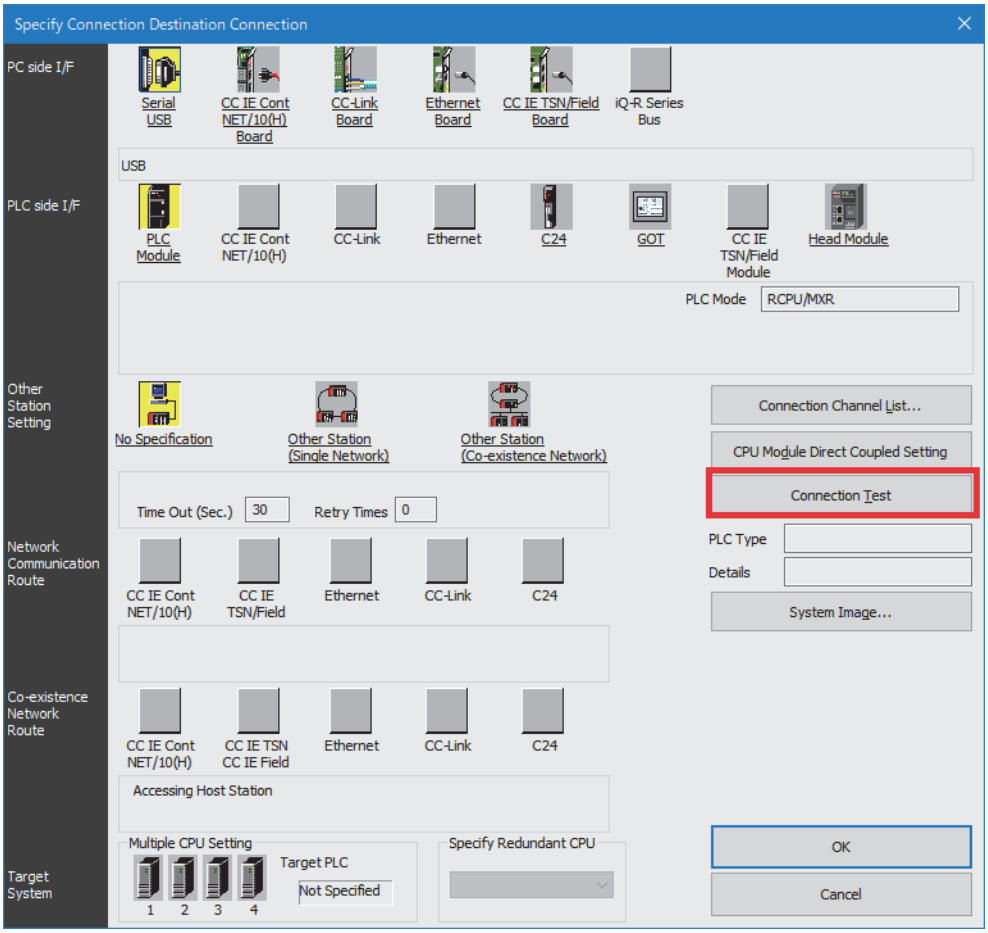


Operating procedure

1. Connect the personal computer to the controller with a USB cable or an Ethernet cable.



2. Click the [CPU Module Direct Coupled Setting] button on the "Specify Connection Destination Connection" window.

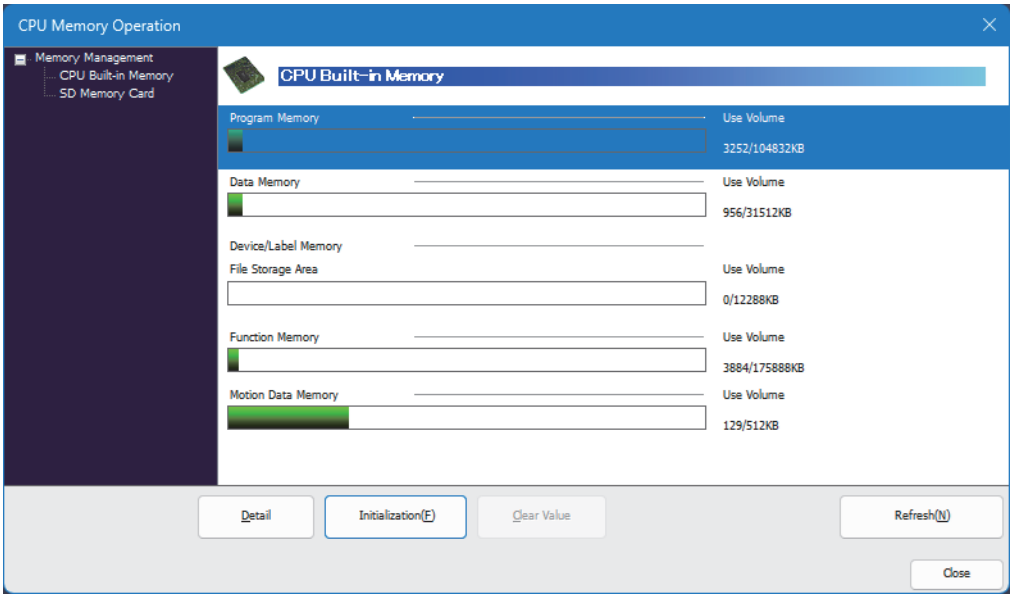


[Online] ⇨ [Current Connection Destination] on the menu bar

3. Select the connection method, and click the [Yes] button. (When selecting "Ethernet", specify the adapter.)

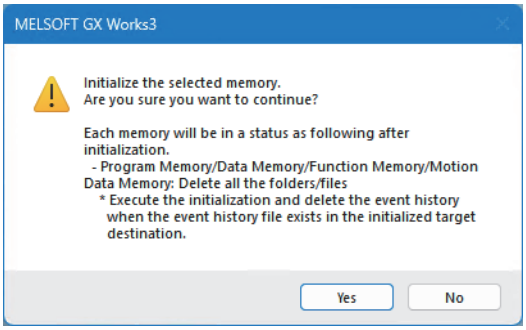
4. Click the [Connection Test] button on the "Specify Connection Destination" window to perform a connection test with the personal computer.

5. If the connection was successful, the successfully connected message appears. Click the [OK] button.



Initializing the controller

Initialize the controller.



Operating procedure

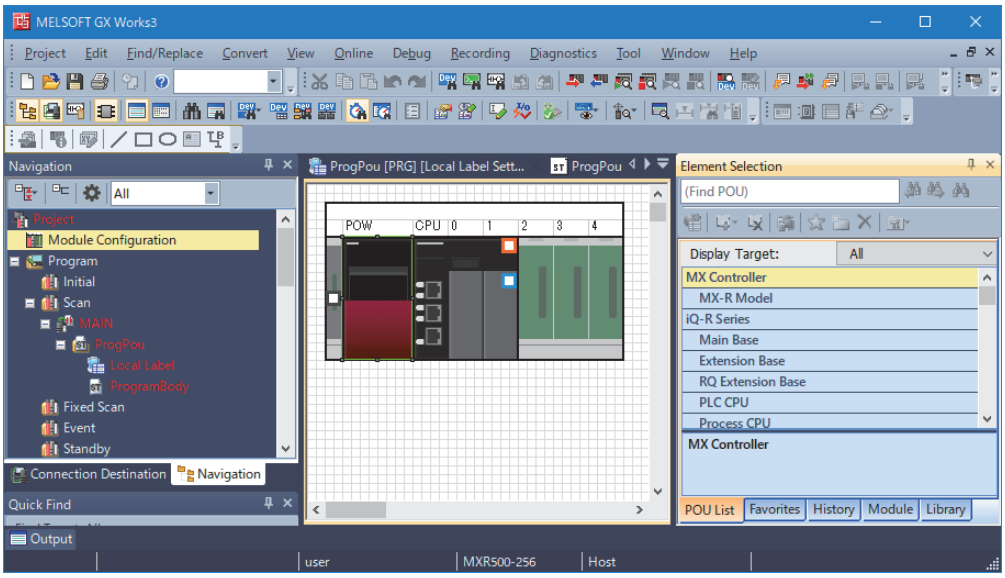
1. Click the [Initialization] button on the "CPU Memory Operation" window.

[Online] ⇨ [CPU Memory Operation] on the menu bar

2. When the confirmation message appears, click the [Yes] button to start initialization.

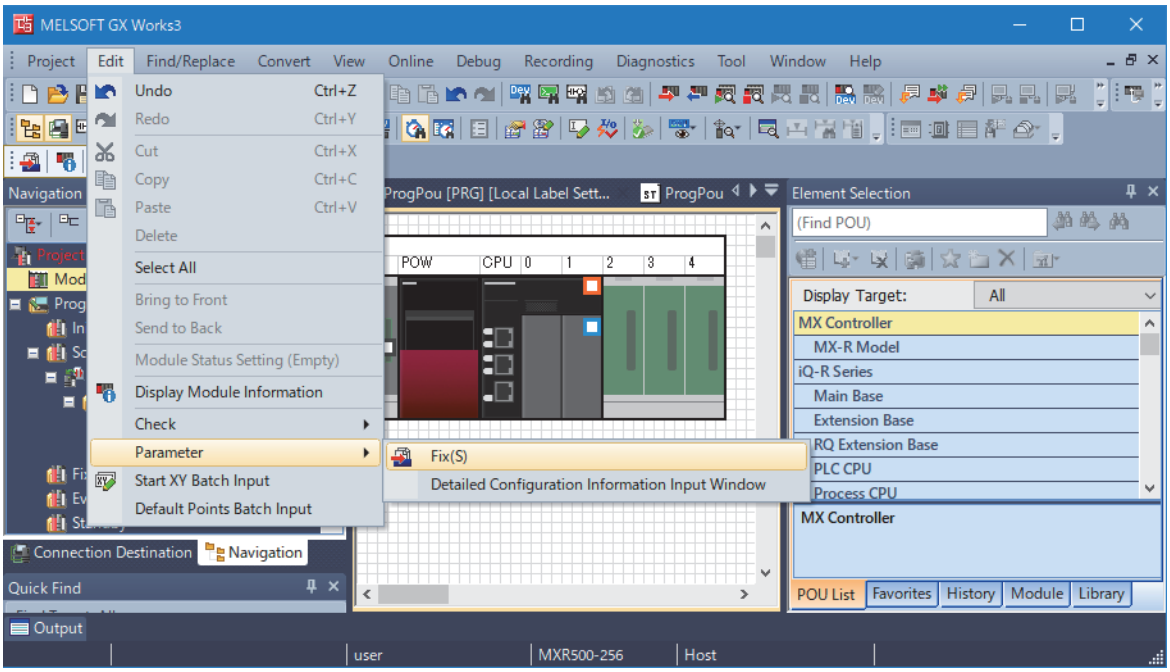
3. When initialization is complete, the completed message is displayed. Click the [OK] button.

5 PARAMETER SETTINGS



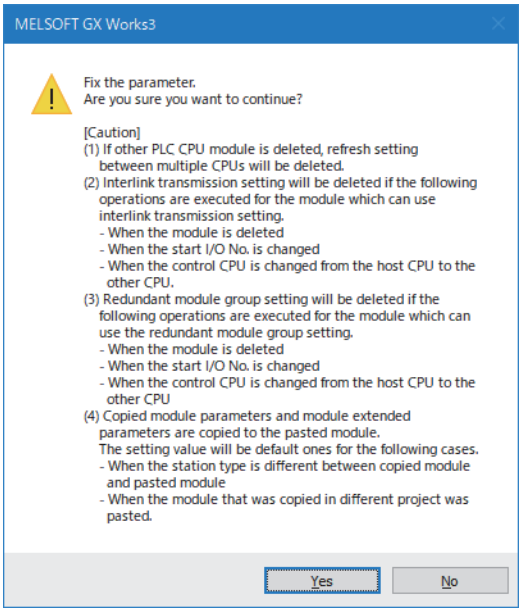
5.1 Creating a Module Configuration

Create a module configuration.



Operating procedure

1. Click the [POU List] tab in the Element Selection window. Select the modules to be used (main base unit and power supply module). Then, drag and drop them into position on the module configuration.

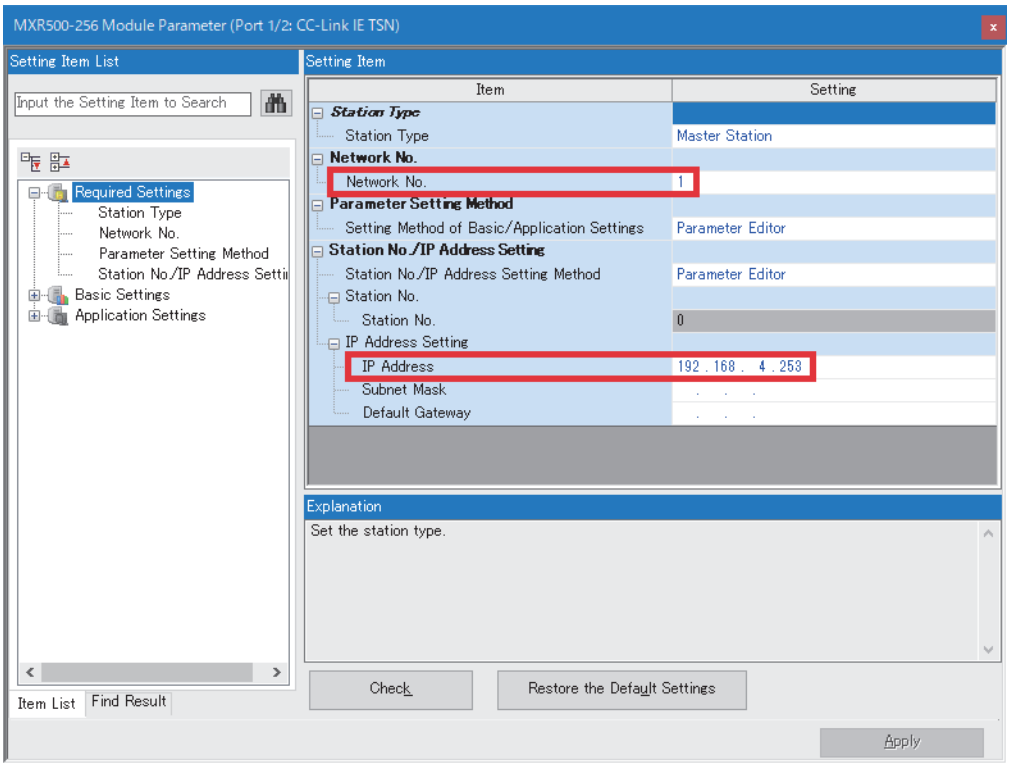


Navigation window ⇨ Double-click [Module Configuration].

2. Select [Edit] ⇨ [Parameter] ⇨ [Fix] on the menu bar.

3. When the confirmation message appears, click the [Yes] button.

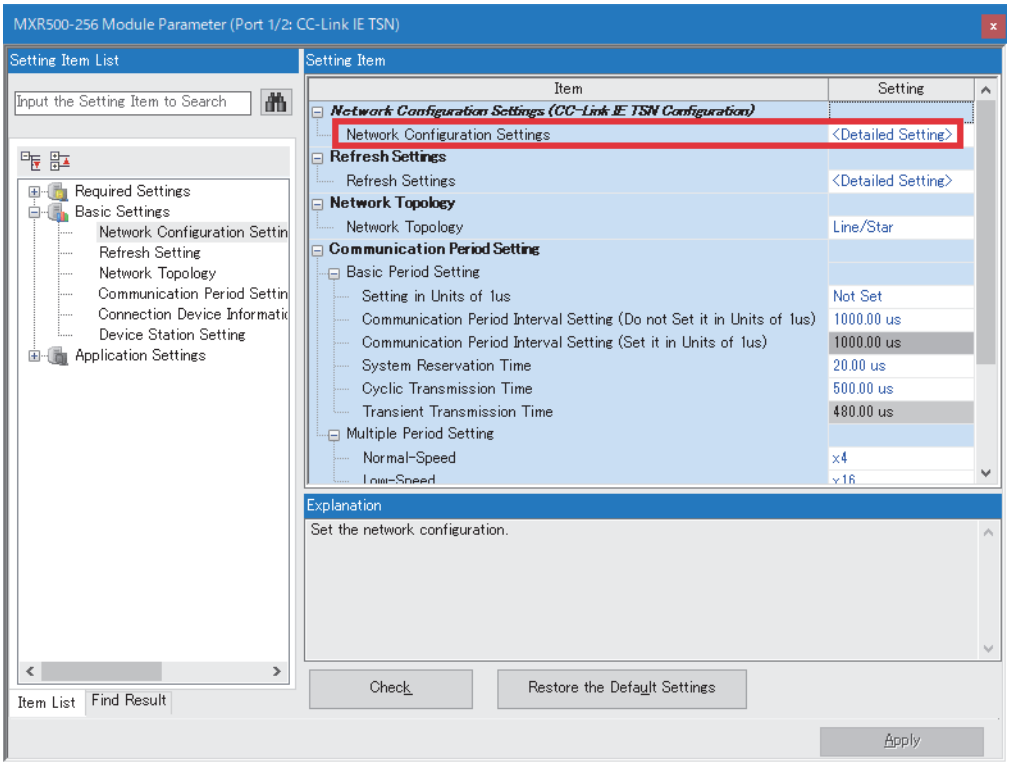
5.2 Network Settings



Set device stations, such as servo amplifiers, to be connected to CC-Link IE TSN.

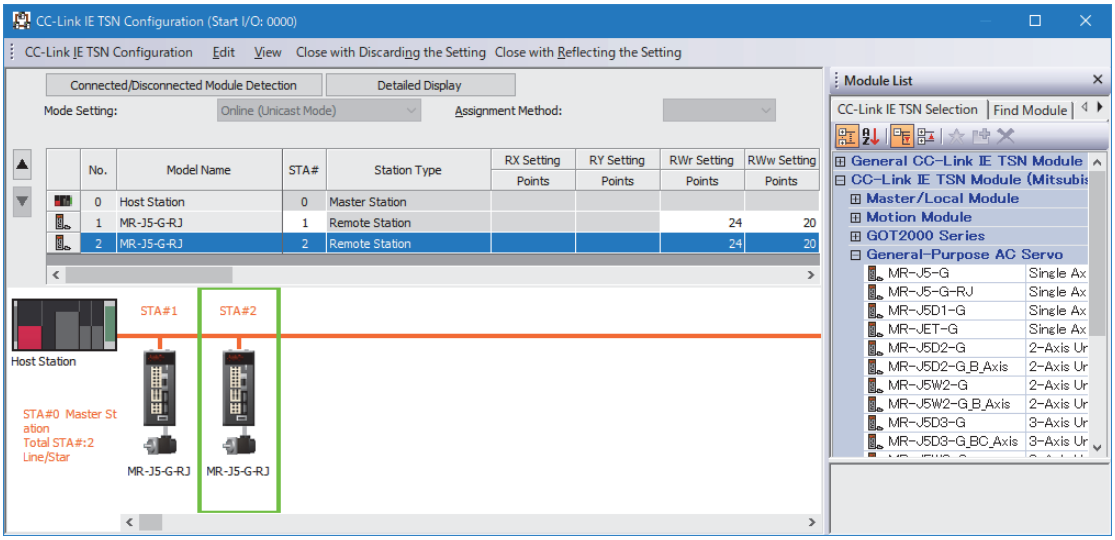
Setting a network configuration

Operating procedure



1. Set "Network No." and "IP Address". The example in this procedure uses the initial value.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [Module Parameter (Port 1/2: CC-Link IE TSN)] ⇨ [Module Parameter (CC-Link IE TSN)] ⇨ [Required Settings]



2. Double-click "<Detailed Setting>" in "Network Configuration Settings".

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [Module Parameter (Port 1/2: CC-Link IE TSN)] ⇨ [Module Parameter (CC-Link IE TSN)] ⇨ [Basic Settings]

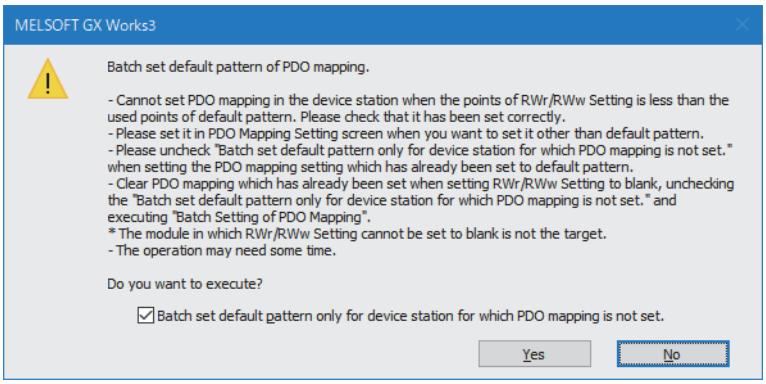
3. Select the devices to be used, and drag and drop them into their assigned position.

[CC-Link IE TSN Selection] tab in the module list ⇨ [General-Purpose AC Servo] in [CC-Link IE TSN Module (Mitsubishi Electric)]

Point

The initial values are displayed in the station No. and the number of I/O points.
The IP address is assigned automatically based on the master station setting, the master station No., and the order the module is dropped.

5.3 Motion Setting



PDO mapping

Set default data of the PDO mapping in a batch.

Operating procedure

1. From the menu on the "CC-Link IE TSN Configuration" window, select "Batch Setting of PDO Mapping" and then click the [Yes] button.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [Module Parameter (Port 1/2: CC-Link IE TSN)] ⇨ [Module Parameter (CC-Link IE TSN)] ⇨ [Basic Settings] ⇨ Double-click <Detailed Setting> ⇨ [CC-Link IE TSN Configuration] ⇨ [Batch Setting of PDO Mapping]

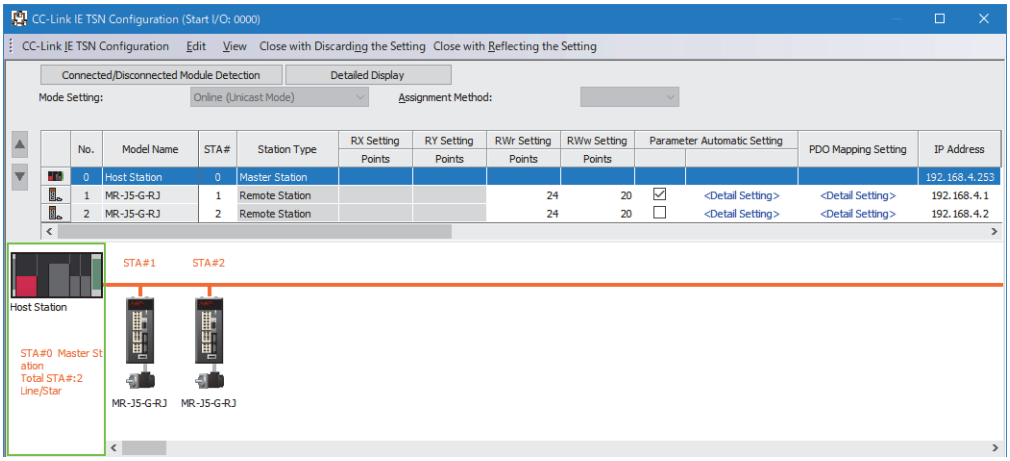
2. When the PDO mapping batch setting completes, the completed message appears. Click the [OK] button.

Point

PDO is an abbreviation for Process Data Object.
PDO communication is equivalent to the conventional CC-Link cyclic transmission.
PDO mapping performs mapping (associating) of data (objects) sent/received between the controller and the devices in cyclic transmission (PDO communication).

Servo parameter settings

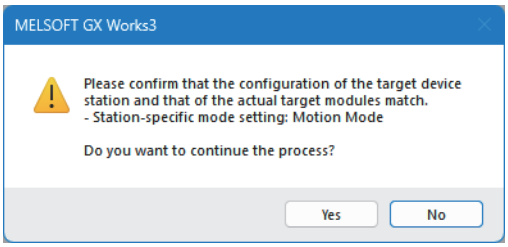
There are two methods for writing parameters to servo amplifiers.



Writing method	Advantage	Disadvantage
Writing from the engineering tool to the controller	• Batch-management of parameters • Setting parameters without connecting servo amplifiers	Taking time at the initial communication
Writing parameters from MR Configurator2 to servo amplifiers	Quick startup of servo amplifiers since transmission of parameters is not necessary at power-on	Necessary to write parameters to each servo amplifier

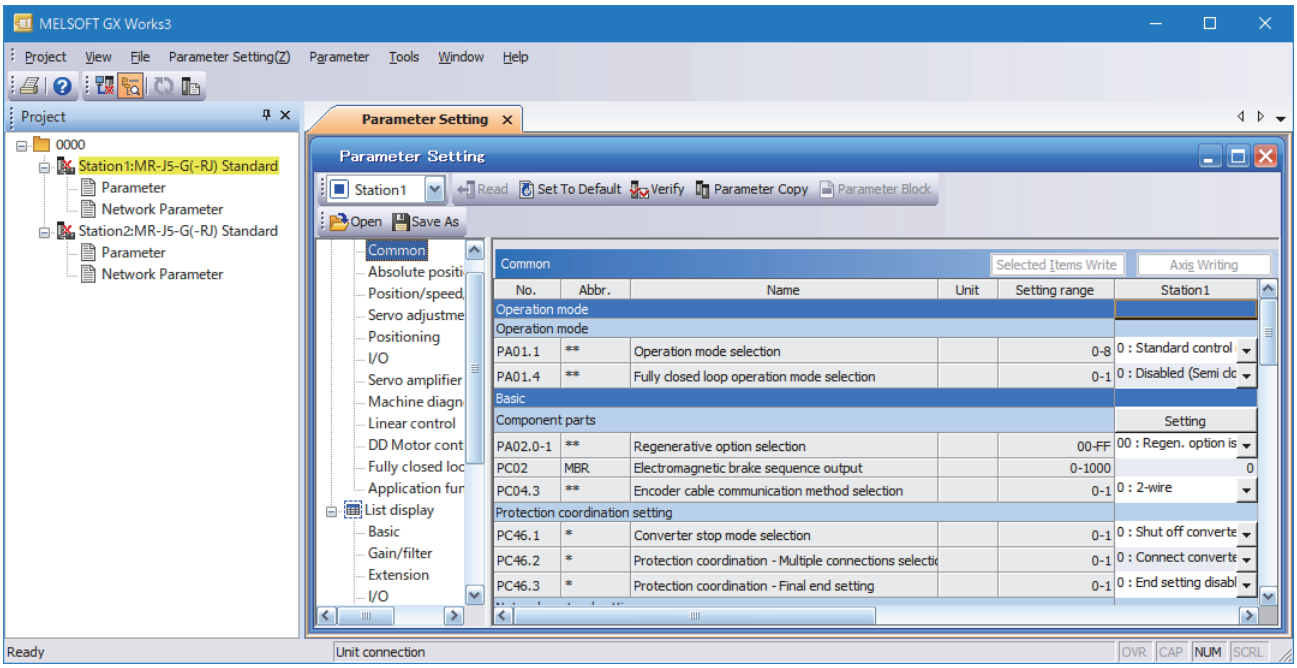
This section describes the procedure for writing from the engineering tool to the controller.

Procedure for writing from the engineering tool to the controller



Operating procedure

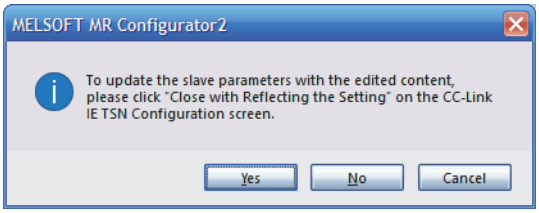
1. Place a check in the "Parameter Automatic Setting" checkbox in the "CC-Link IE TSN Configuration" window to write parameters to the device stations from the master station at the initial communication.



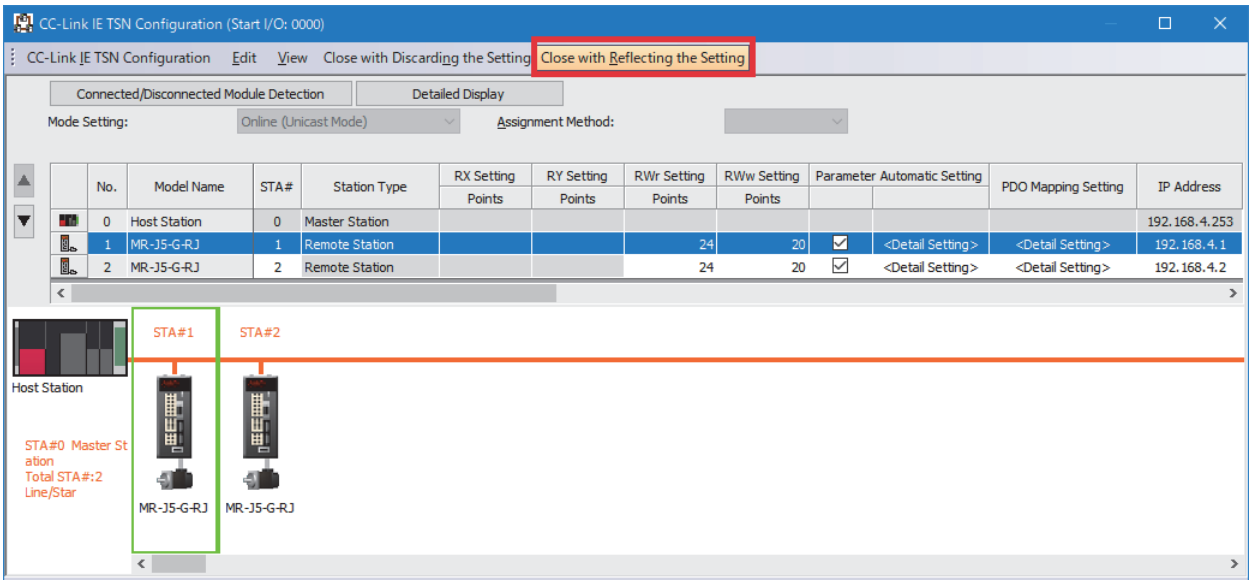
2. Double-click the illustration of the servo amplifier to be set.

3. When the confirmation message appears, click the [Yes] button.

4. On the "Parameter Setting" window, set the servo parameters.

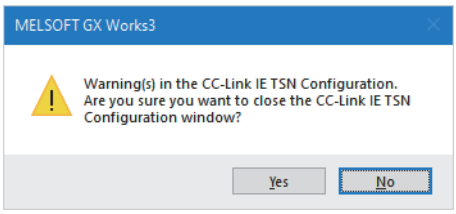


Change the following parameters.

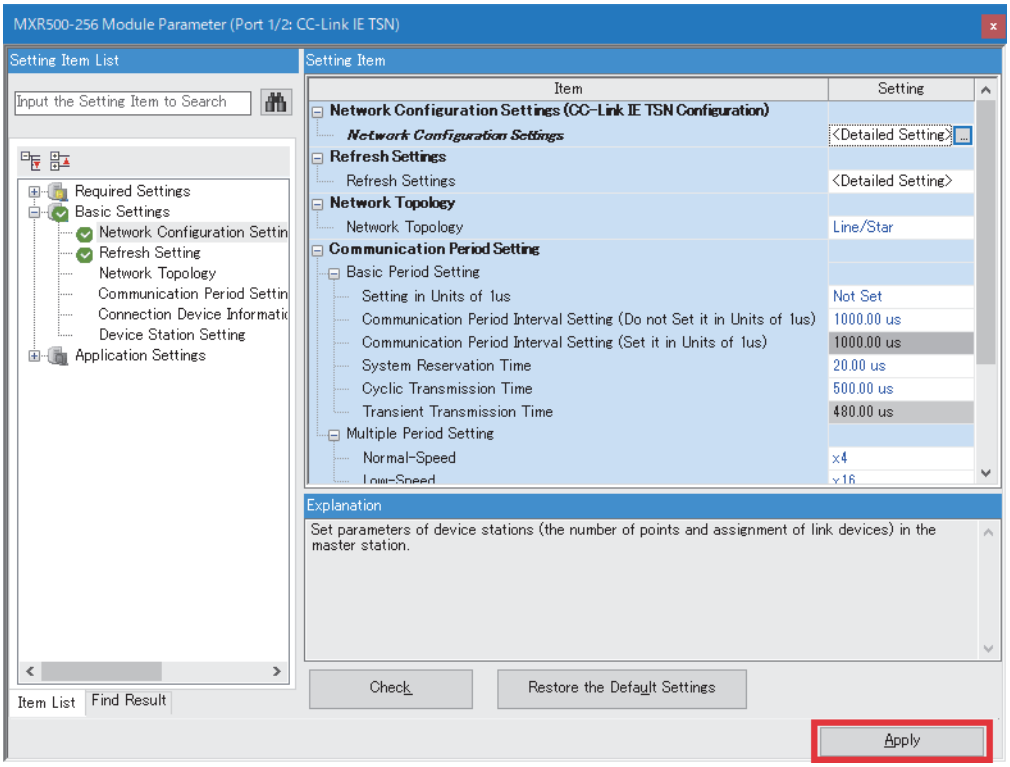


Operation	No.	Parameter	Setting value
[Common] ⇨ [Basic] ⇨ [Forced stop]	PA04.2	Servo forced stop selection	0: Enabled (Use forced stop input EM1 or EM2.) → 1: Disabled (The forced stop input EM1 and EM2 are not used.)
[I/O] ⇨ [Stroke limit function] ⇨ [Stroke limit function]	PC19.0	[AL.099 Stroke limit warning] selection	0: Enabled → 1: Disabled
	PD41.2	Limit switch enabled status selection	0: Limit switch always enabled → 1: Enabled only for homing mode

5. When the setting is complete, click the [×] button in the upper right corner of the "Parameter Setting" window.



6. When the confirmation message appears, click the [Yes] button to update the parameters.



7. From the menu on the "CC-Link IE TSN Configuration" window, click the "Close with Reflecting the Setting" button.

If the following warning message appears, click the [Yes] button.

8. In the module parameters, click the [Apply] button to reflect the parameters of the controller.

Point

Changes made to parameters will be reflected only after the [Apply] button is clicked.

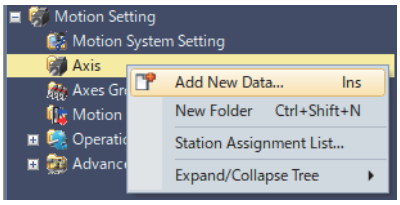
Axis parameter settings

Setting a station address and an axis type

There are five axis types.

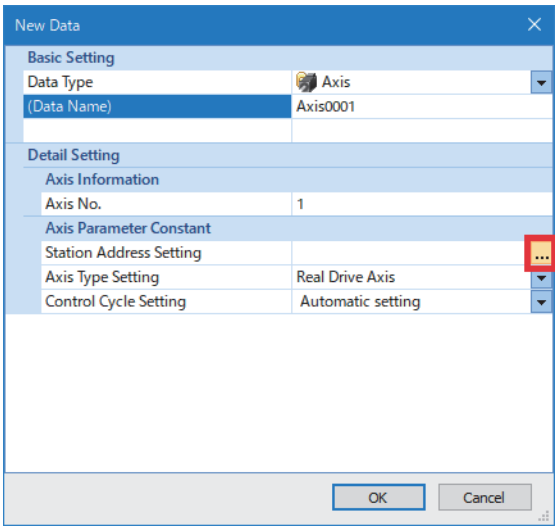
Axis type	Description
Real drive axis	Outputs commands using a servo amplifier connected to CC-Link IE TSN.
Real encoder axis	Generates the current position from the output pulses of the synchronous encoder which is connected to a servo amplifier on CC-Link IE TSN.
Virtual drive axis	Virtually generates commands.
Virtual encoder axis	Virtually generates the current position from the variables.
Virtual linked axis	Virtually connects the single axis synchronous control FBs.

The example in this section registers two real drive axes, one virtual drive axis, and two virtual linked axes.



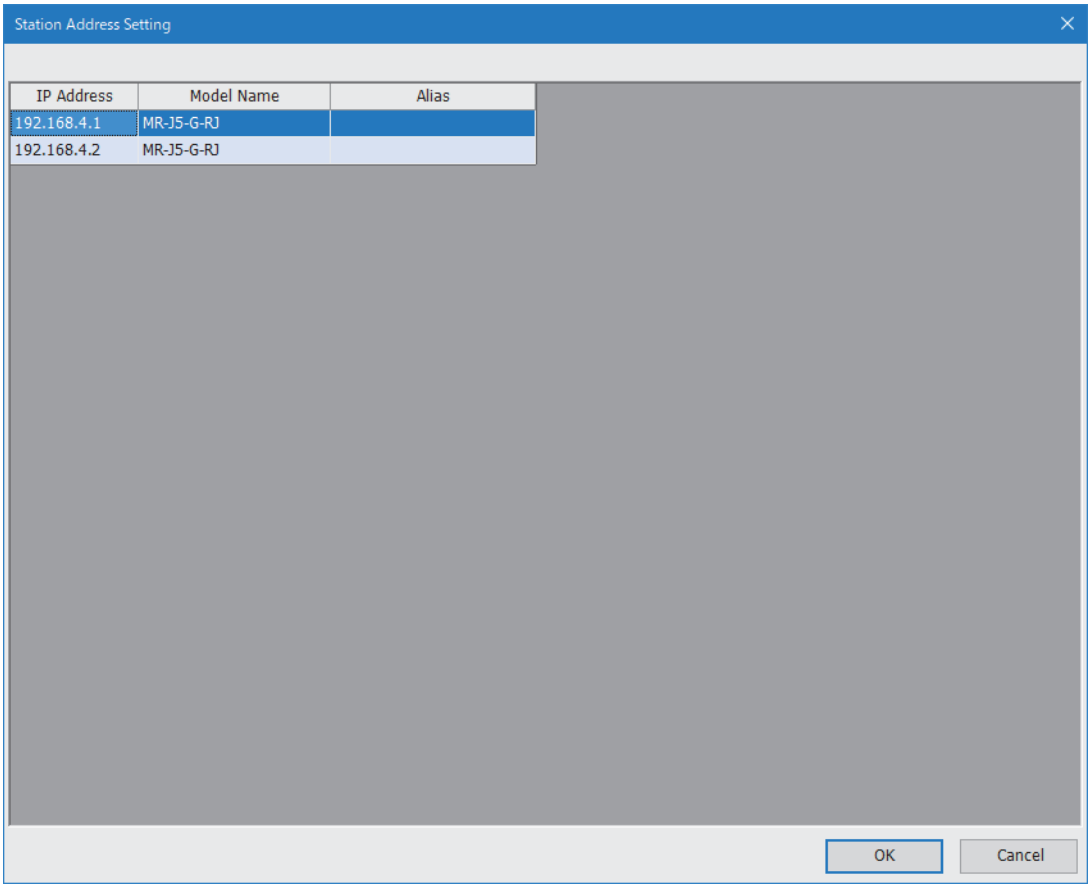
Real drive axis

Set the station address to link the axis information in the axis parameter to the servo amplifier set in the network configuration.

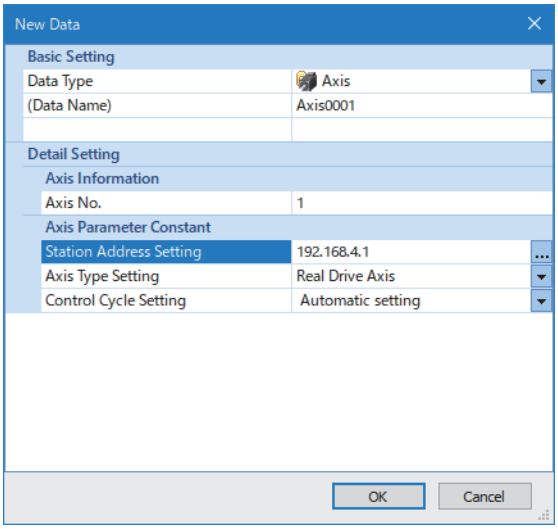


Operating procedure

1. Right-click "Axis" in the navigation window, and select "Add New Data".



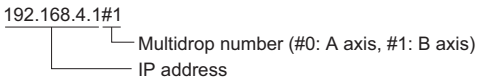
Navigation window ⇨ [Motion Setting] ⇨ [Axis]



2. Click the [...] button on "Station Address Setting" to display the "Station Address Setting" window.

3. The station address can be set by selecting one of the IP addresses displayed on the "Station Address Setting" window and clicking the [OK] button.

4. Enter "Data Name", "Axis No.", "Station Address Setting", and "Axis Type Setting", and click the [OK] button.

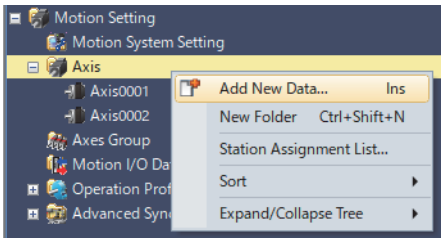


■Real drive axis setting description

Item	Setting value (1st axis)	Setting value (2nd axis)
Data Name	Axis0001	Axis0002
Axis No.	1	2
Station Address Setting	192.168.4.1	192.168.4.2
Axis Type Setting	Real Drive Axis	Real Drive Axis

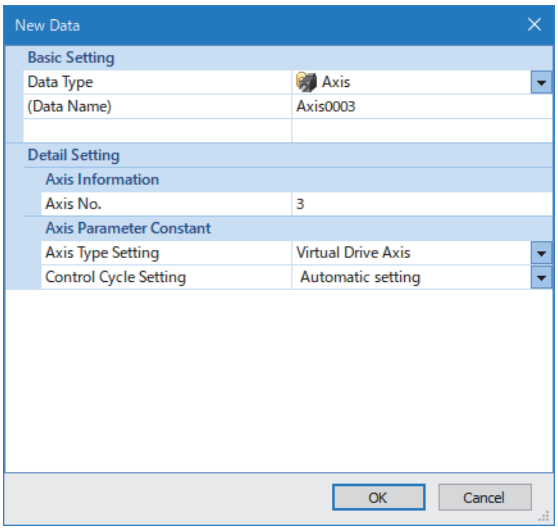
Point

For the station address setting, use the IP address set in the "CC-Link IE TSN Configuration" window.
A multi-drop No. is shown when the station address for axes other than the first axis of a multi-axis servo amplifier is specified.
(Example) For B-axis of the MR-J5-W3 with "IP address: 192.168.4.1"



Virtual drive axis

Set a virtual drive axis.



Operating procedure

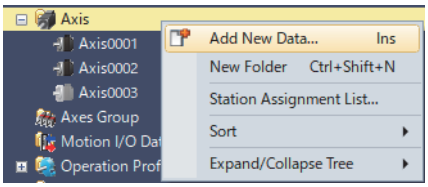
1. Right-click "Axis" in the navigation window, and select "Add New Data".

Navigation window ⇨ [Motion Setting] ⇨ [Axis]

2. Enter "Data Name", "Axis No.", and "Axis Type Setting", and click the [OK] button.

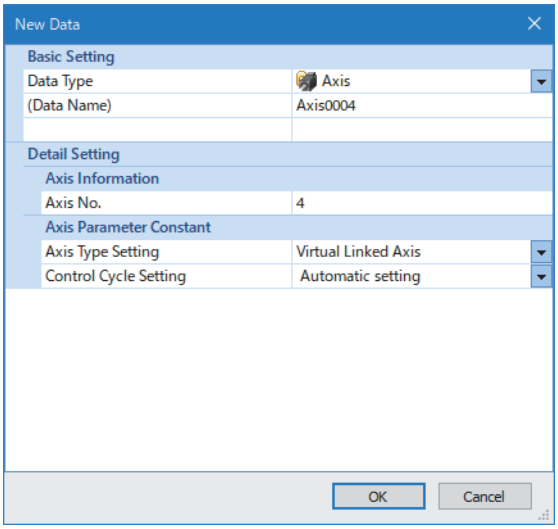
■Virtual drive axis setting description

Item	Setting value
Data Name	Axis0003
Axis No.	3
Axis Type Setting	Virtual Drive Axis



Virtual linked axis

Set a virtual linked axis.



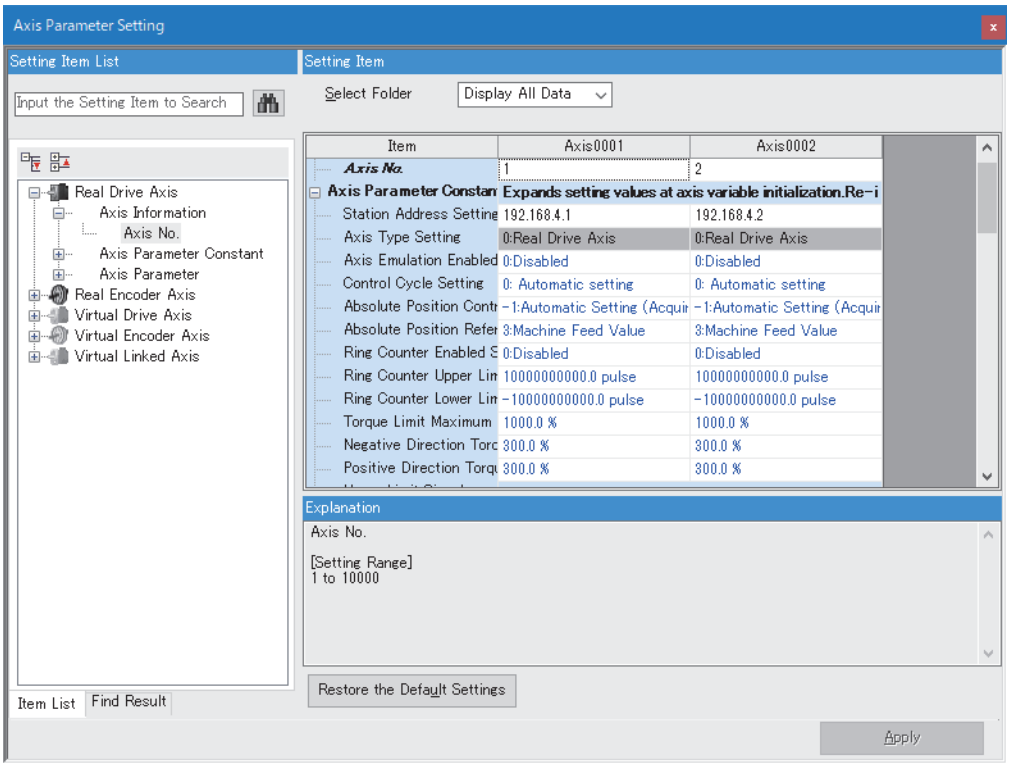
Operating procedure

1. Right-click "Axis" in the navigation window, and select "Add New Data".

Navigation window ⇨ [Motion Setting] ⇨ [Axis]

2. Enter "Data Name", "Axis No.", and "Axis Type Setting", and click the [OK] button.

■Virtual linked axis setting description



Item	Setting value (1st axis)	Setting value (2nd axis)
Data Name	Axis0004	Axis0005
Axis No.	4	5
Axis Type Setting	Virtual Linked Axis	Virtual Linked Axis

Setting each item

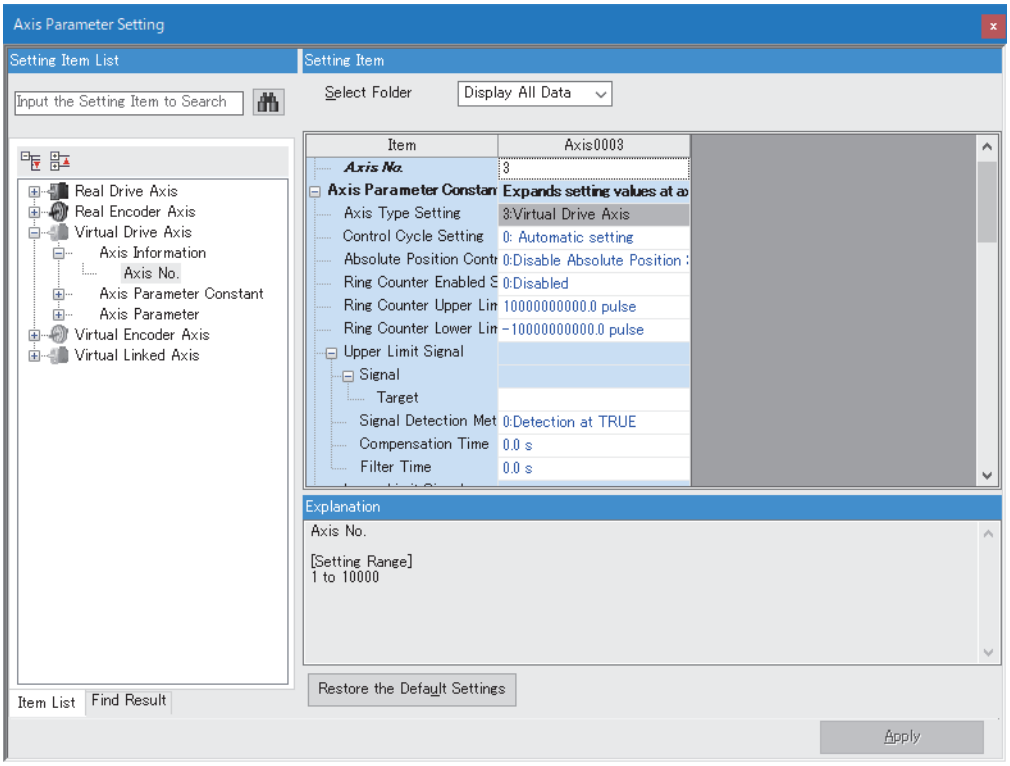
■Real drive axis

1. In the "Axis Parameter Setting" window, set the axis parameters for Axis0001 and Axis0002.

Navigation window ⇨ [Motion Setting] ⇨ [Axis] ⇨ Double-click Axis0001 (Axis0002).

Set the real drive axes (Axis0001 and Axis0002) as shown below.

Item				Description	Setting value	
					Axis0001	Axis0002
Axis Parameter Constant	Station Address Setting			Set the IP address of the driver.	192.168.4.1	192.168.4.2
	Upper Limit Signal			Set the hardware stroke limit switches at the upper/lower limit of the movable range by assigning external signals.	Initial value	
	Lower Limit Signal					
Axis Parameter	Driver Unit Conversion Numerator			Convert units of the target position and the actual position between the controller and the driver. For details on the setting method, refer to the following. ☞ Page 86 Driver unit conversion (electronic gear)	67108864	
	Driver Unit Conversion Denominator				5000	
	Forced Stop Signal			Set the forced stop signal.	Initial value	
	Stop Signal	Signal	Target	Set the stop signal.	[VAR]G_bStopSignalX*1	[VAR]G_bStopSignalY*1
		Signal Detection Method			Initial value	
		Compensation Time				
		Filter Time				
	Start Permission at Homing Uncompleted			Set whether axis start is allowed or not for when the homing request is TRUE.	Initial value	
	Software Stroke Limit Lower Value			Set the range and the target of the software stroke limit.	Initial value	
	Software Stroke Limit Target					
	Software Stroke Limit Upper Value					
	Position Command Unit			Set the position command unit and the velocity command unit used for the motion control.	um*2	
	Velocity Command Unit				U/s	



*1 A global label is registered for the stop signal. For setting the global labels, refer to the following.
☞ Page 107 Global label list

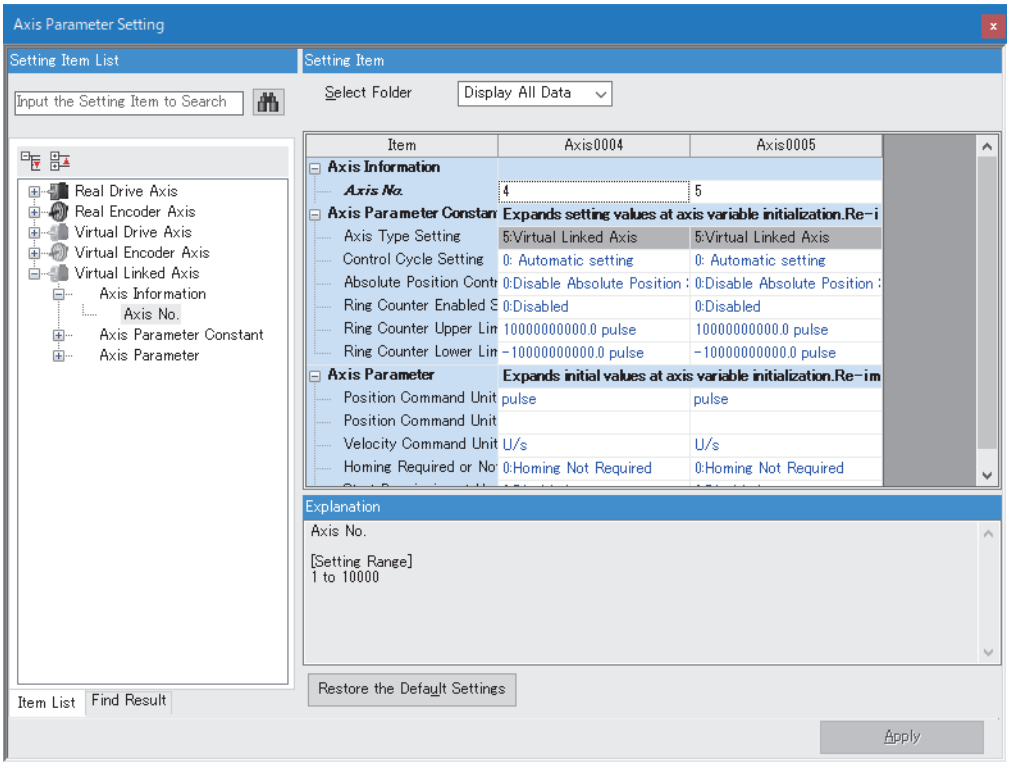
*2 um indicates micrometer (μm).

■Virtual drive axis

1. In the "Axis Parameter Setting" window, set the axis parameters for Axis0003.

Navigation window ⇨ [Motion Setting] ⇨ [Axis] ⇨ Double-click Axis0003.

Set the virtual drive axis (Axis0003) as shown below.



Item		Description	Setting value
			Axis0003
Axis Parameter	Position Command Unit	Set the position command unit and the velocity command unit used for the motion control.	um*1
	Velocity Command Unit		U/s

*1 um indicates micrometer (μm).

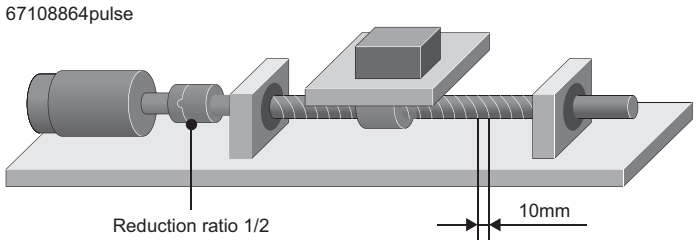
■Virtual linked axis

1. In the "Axis Parameter Setting" window, set the axis parameters for Axis0004 and Axis0005.

Navigation window ⇨ [Motion Setting] ⇨ [Axis] ⇨ Double-click Axis0004 (Axis0005).

Set the virtual linked axes (Axis0004 and Axis0005) as shown below.

Item		Description	Setting value	
			Axis0004	Axis0005
Axis Parameter	Position Command Unit	Set the position command unit and the velocity command unit used for the motion control.	um*1	um*1
	Velocity Command Unit		U/s	U/s



*1 um indicates micrometer (μm).

Driver unit conversion (electronic gear)

A setting example of the driver unit conversion numerator/driver unit conversion denominator is shown below.

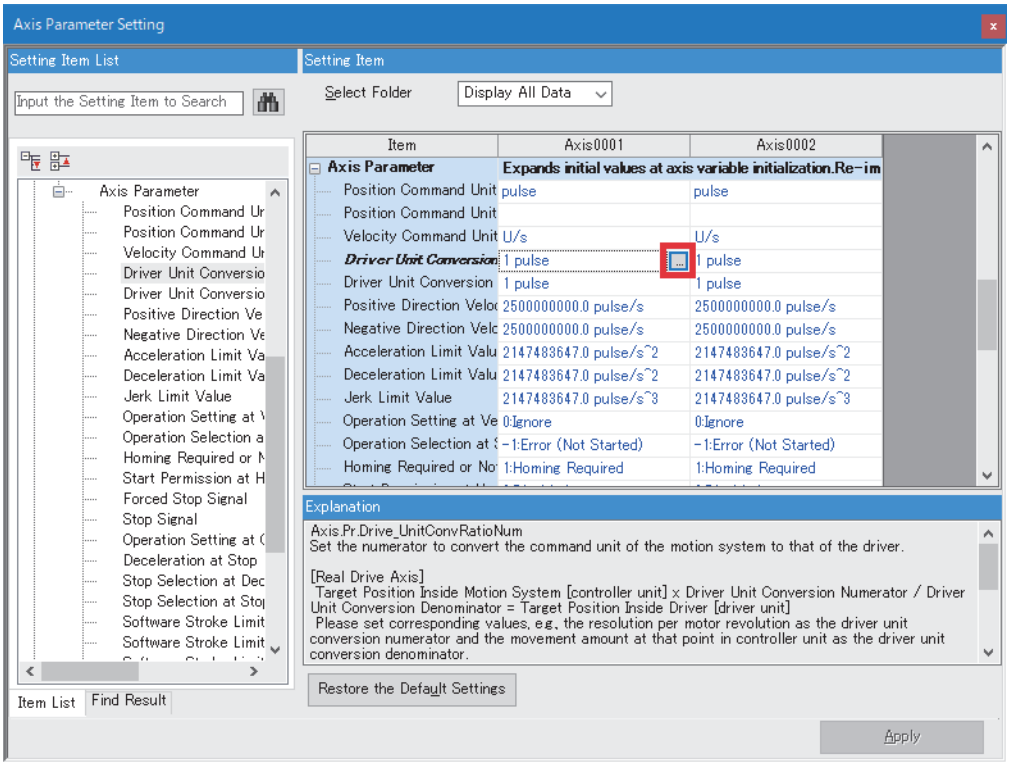
About the electronic gear

■Ball screw

Item	Setting value
Servo motor encoder resolution	67108864 pulse (26 bits)
Lead of the ball screw	10mm (10000μm)
Reduction ratio	1/2 (load side [NL]/motor side [NM]) Each time the servo motor rotates twice, the ball screw of the load side rotates once.

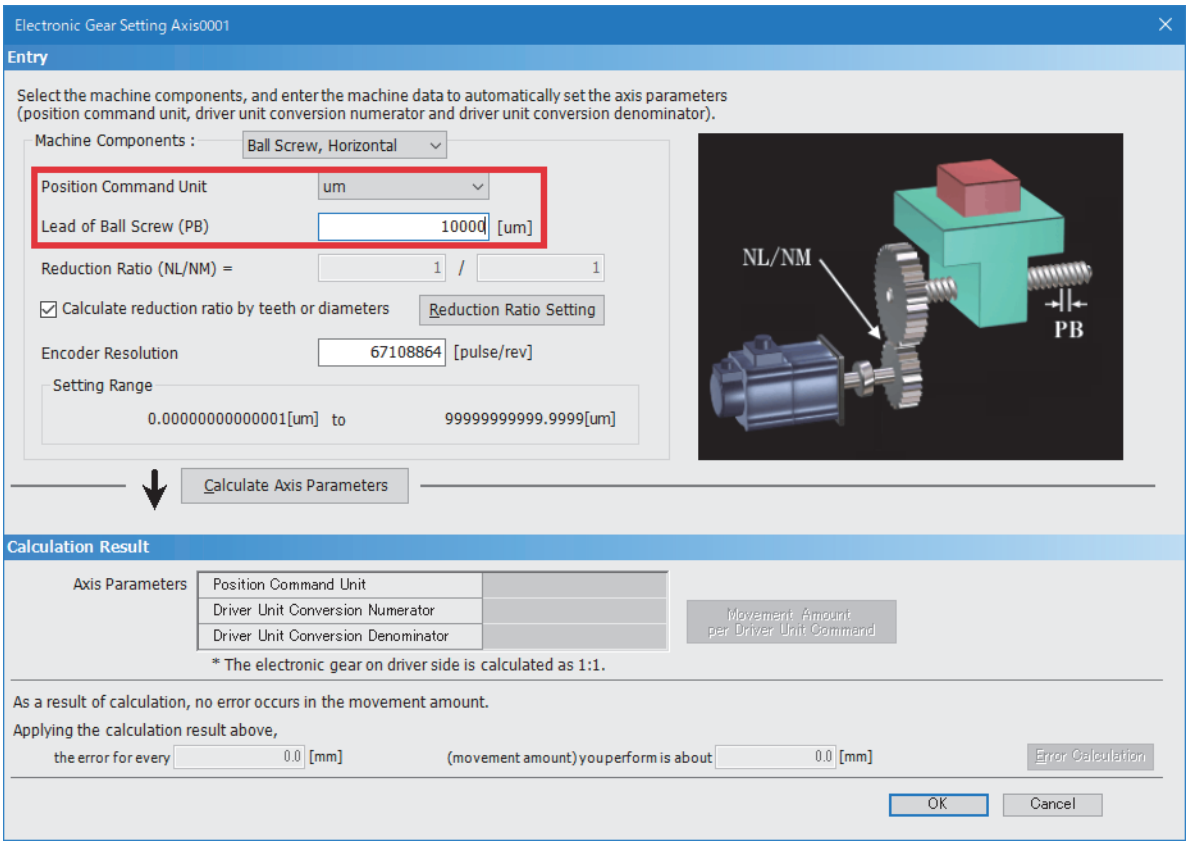
$$\frac{\text{Driver unit conversion numerator}}{\text{Driver unit conversion denominator}} = \frac{\text{Number of encoder pulses}}{\text{Movement amount} \times \text{Reduction ratio}} = \frac{67108864}{10000 \times 1/2} = \frac{67108864}{5000}$$

- Driver unit conversion numerator = Number of pulses per rotation 67108864
- Driver unit conversion denominator = Movement amount per rotation 5000



Electronic gear setting

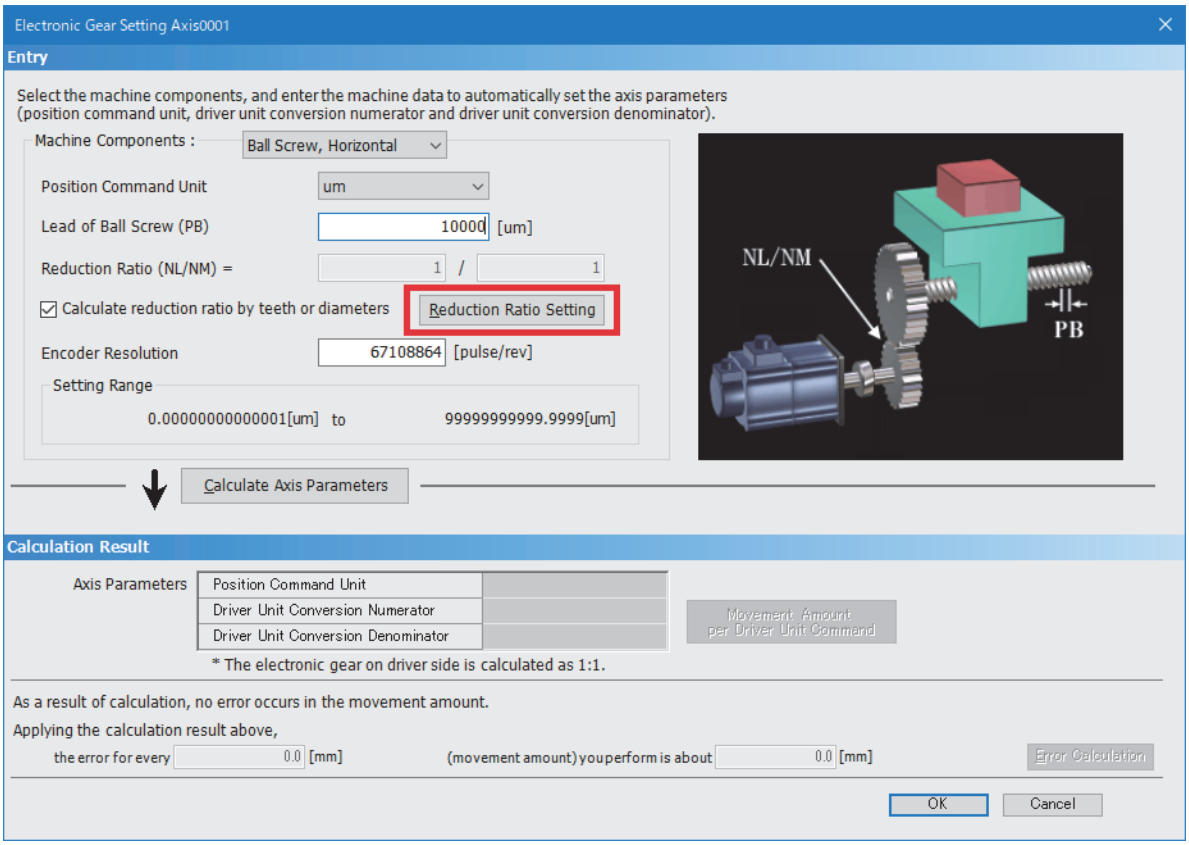
The procedure for setting the electronic gear is shown below.



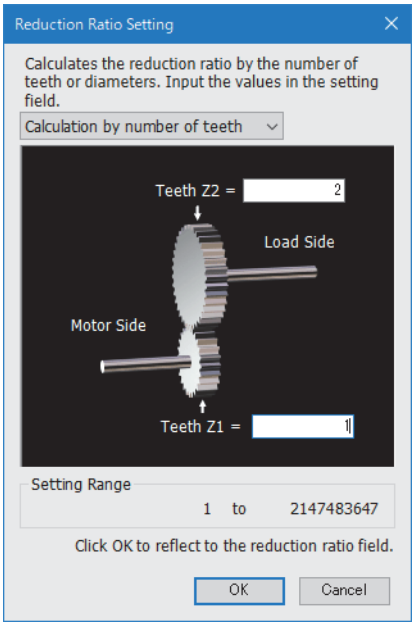
Operating procedure

1. In the "Axis Parameter Setting" window, click "Axis Parameter" ⇨ [...] button for "Driver Unit Conversion Numerator" to display the "Electronic Gear Setting" window.

Navigation window ⇨ [Motion Setting] ⇨ [Axis] ⇨ Double-click Axis0001.



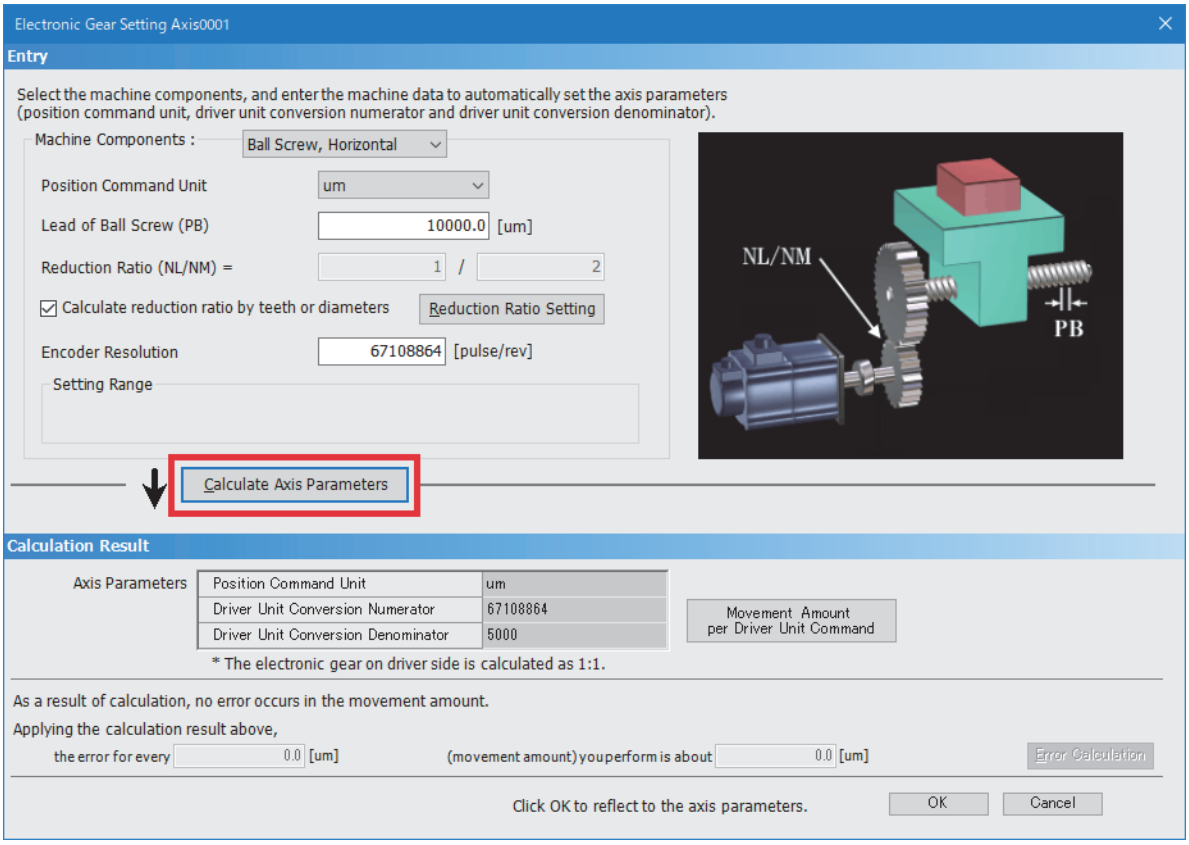
2. Enter each item of the machine components.



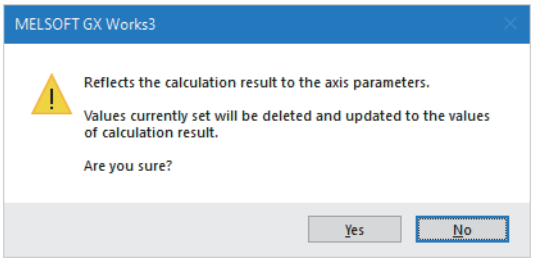
The following table lists the settings to change.

Item	Setting value
Position Command Unit	um
Lead of Ball Screw (PB)	10000.0

3. Click the "Reduction Ratio Setting" button to open the "Reduction Ratio Setting" window.



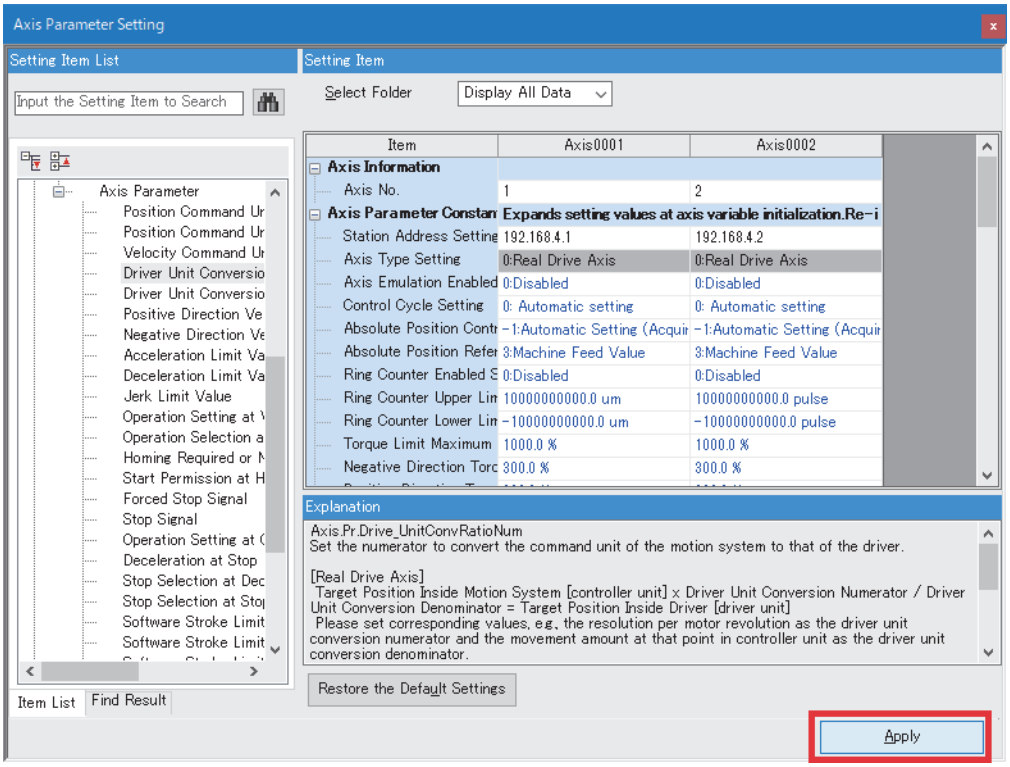
4. Set the number of teeth and click the [OK] button.



The following table lists the settings.

Item	Setting value
Teeth Z2	2
Teeth Z1	1

5. Click the [Calculate Axis Parameters] button to display the calculation result. Check the calculation result, and click the [OK] button.



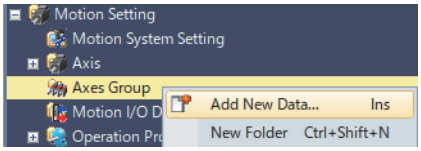
6. When the confirmation message appears, click the [Yes] button. The calculation result is reflected in the axis parameters.

Reflecting axis parameters

After setting each item, click the [Apply] button to fix the parameters.

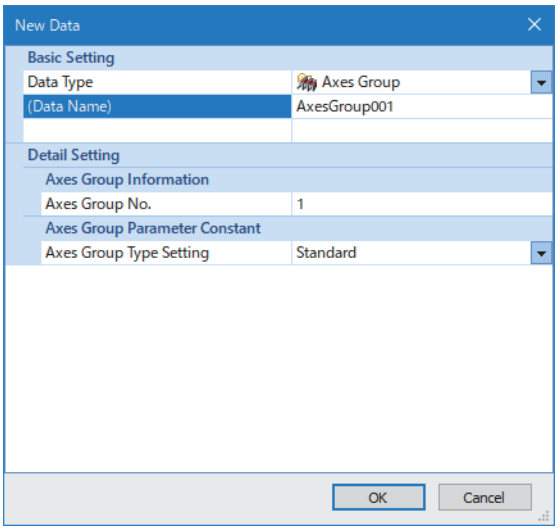
Point

Changes made to parameters will be reflected only after the [Apply] button is clicked.



Axes group settings

An axes group is used for multiple axes control such as linear interpolation and circular interpolation.
An axes group does not need to be created for axes used for synchronous control.
This section describes the procedure for registering the X axis (Axis0001) and Y axis (Axis0002) in an axes group.

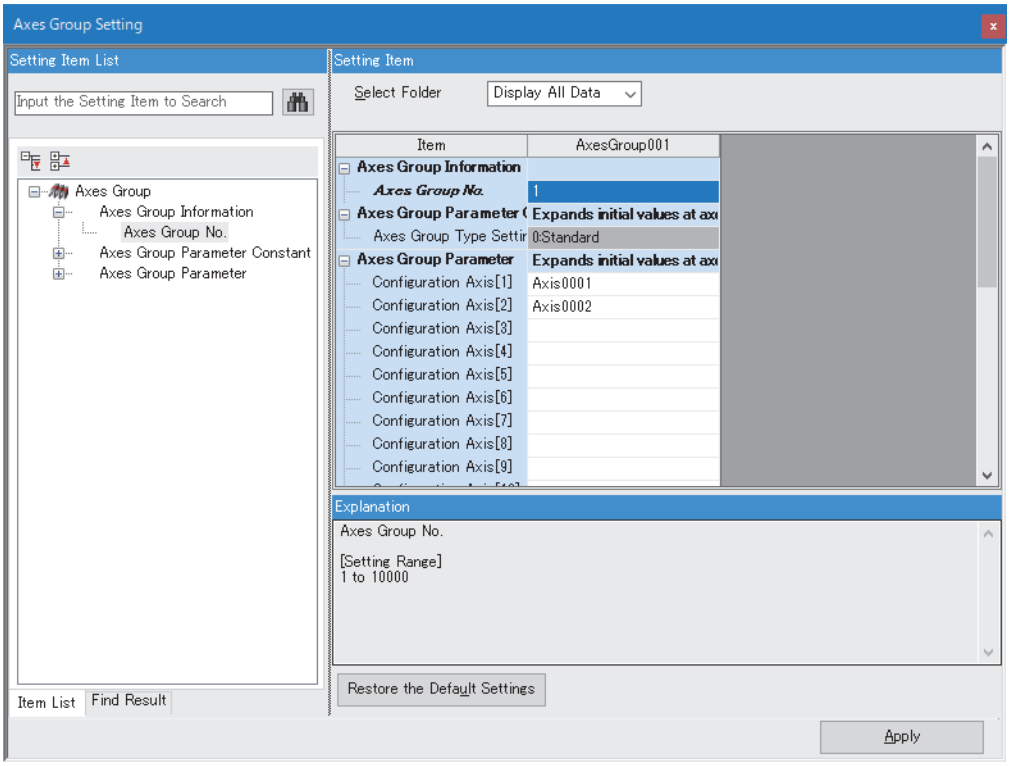


Axes group

1. Right-click "Axes Group" in the navigation window, and select "Add New Data".

Navigation window ⇨ [Motion Setting] ⇨ [Axes Group]

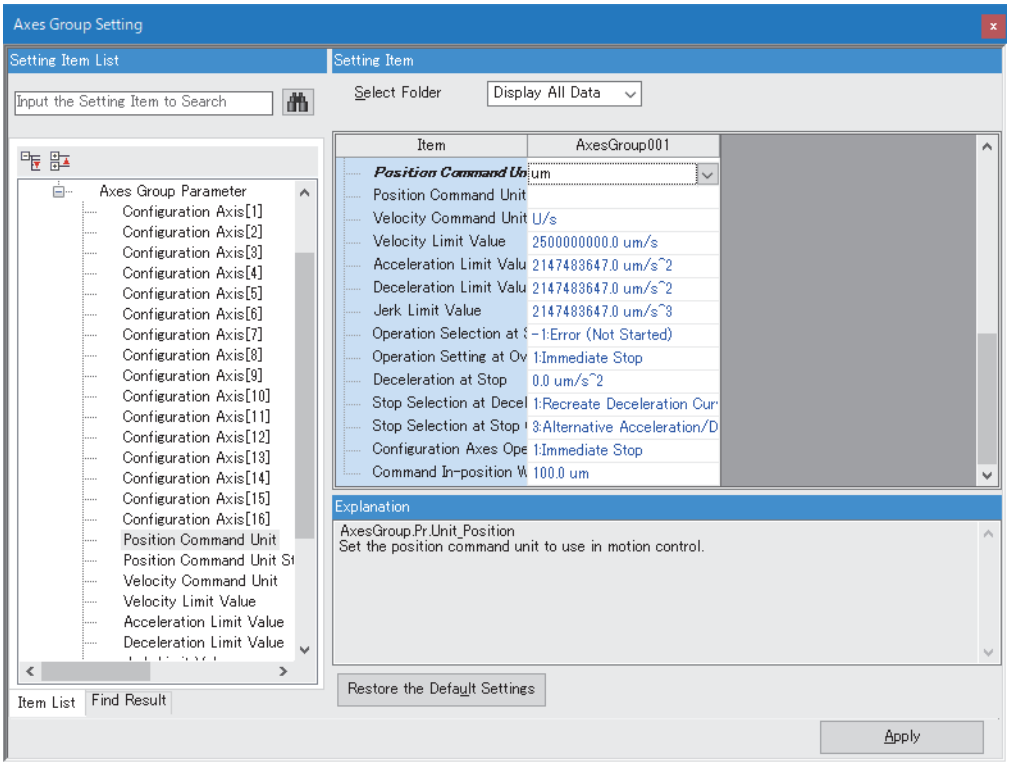
2. Enter "Data Name", the "Axes Group No.", and click the [OK] button.



The following table lists the settings.

Setting item	Setting value
Data Name	AxesGroup001
Axes Group No.	1

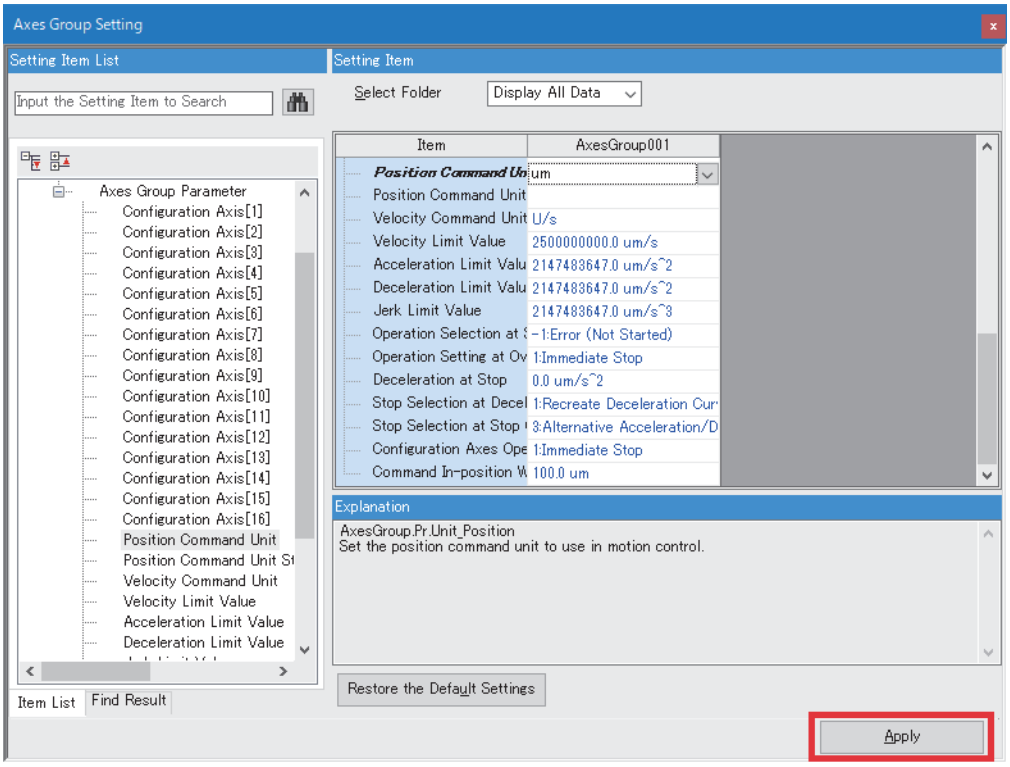
3. Display the "Axes Group Setting" window. Set the axes group parameters of AxesGroup001.



Navigation window ⇨ [Motion Setting] ⇨ [Axes Group] ⇨ Double-click AxesGroup001.

• Axes group configuration axis setting example

Item	Setting value
Configuration Axis[1]	Axis0001
Configuration Axis[2]	Axis0002

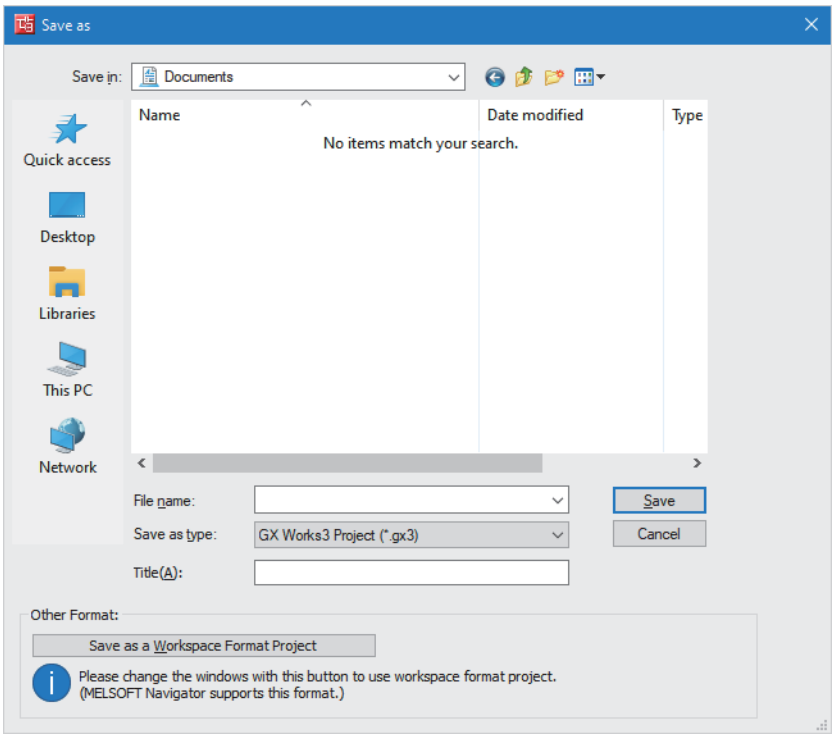


• Axes group units setting example

Item	Setting value
Position Command Unit	um*1

*1 um indicates micrometer (μm).

4. After setting the items for each axes group, click the [Apply] button to fix the axes group parameter setting.



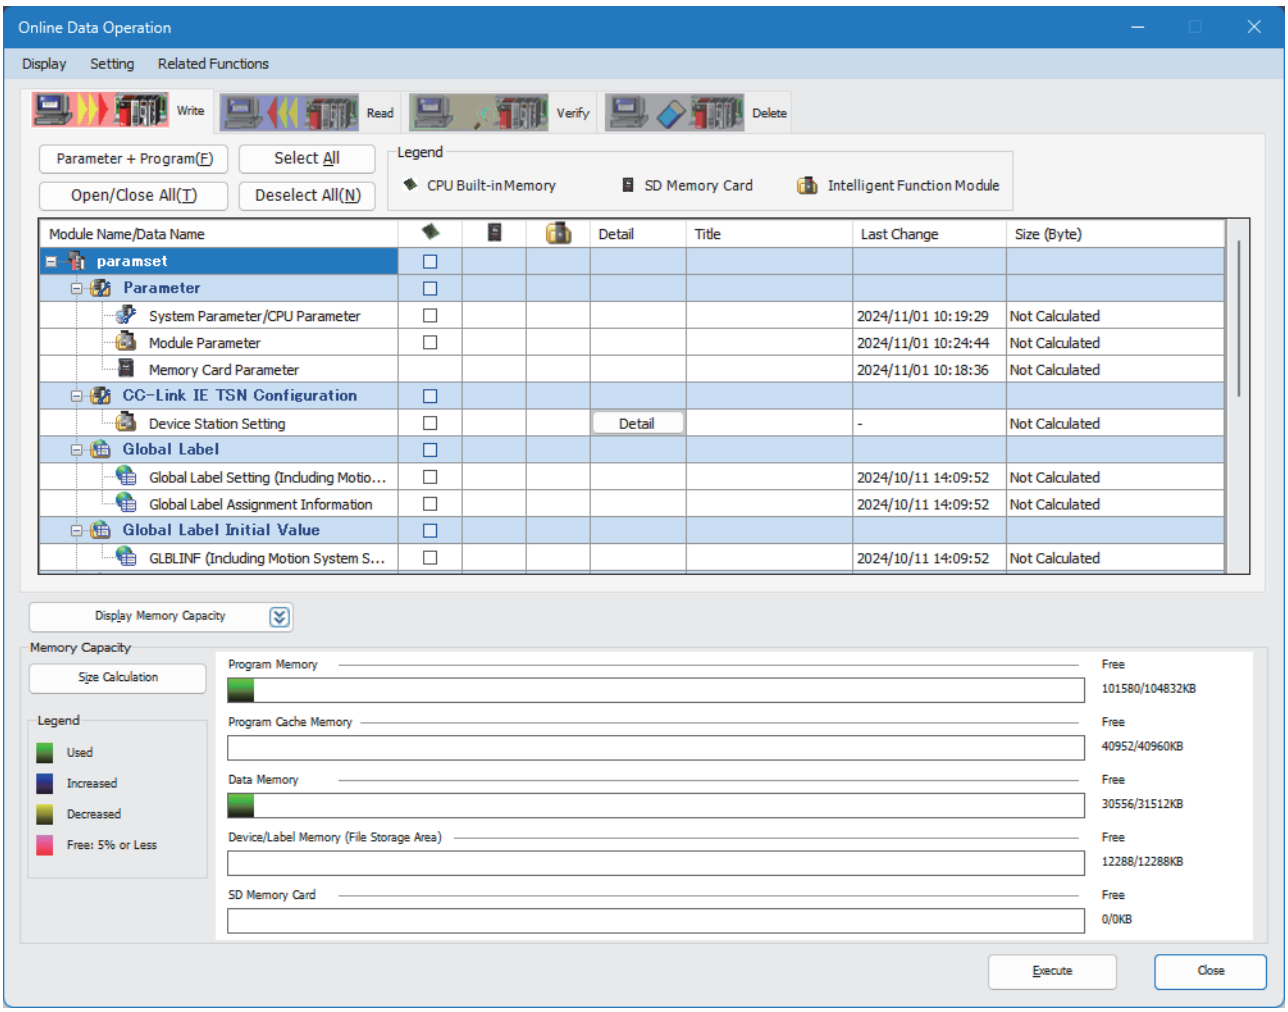
Point

Changes made to parameters will be reflected only after the [Apply] button is clicked.

5.4 Saving a Project

Save the created project.

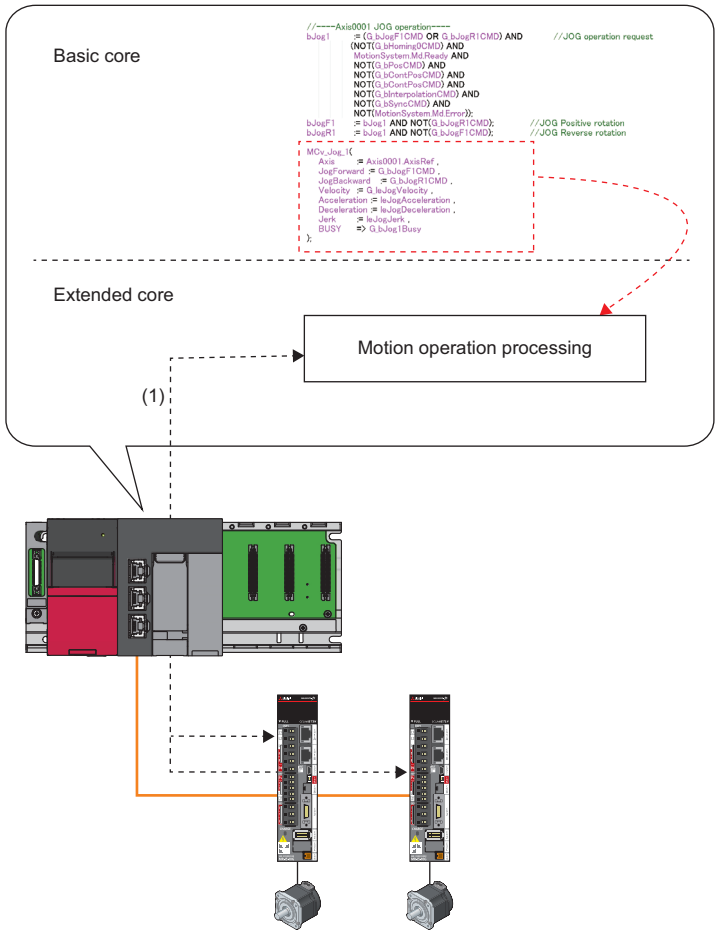
1. In the engineering tool, select [Project] ⇨ [Save as] on the menu bar to display the "Save as" window. Enter a file name, and click the [Save] button.



5.5 Writing to the Controller

After writing the module parameters to the controller, reset it or turn the power off and on.

Operating procedure



1. Select [Online] ⇨ [Write to PLC] on the menu bar to display the "Online Data Operation" window. Check the items to be written on the window, and click the [Execute] button.

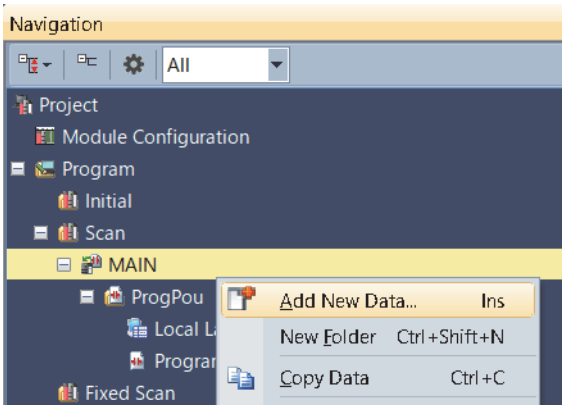
2. The parameters are written to the controller.
3. When the writing is complete, a completed message is displayed. Click the [OK] button.
   Reset the controller or turn the power off and on again to check that no error occurs. Errors can be checked on the LED indicator of the controller or the system monitor of the engineering tool.

6 PROGRAM EXAMPLES

The example in this chapter uses the structured text language.

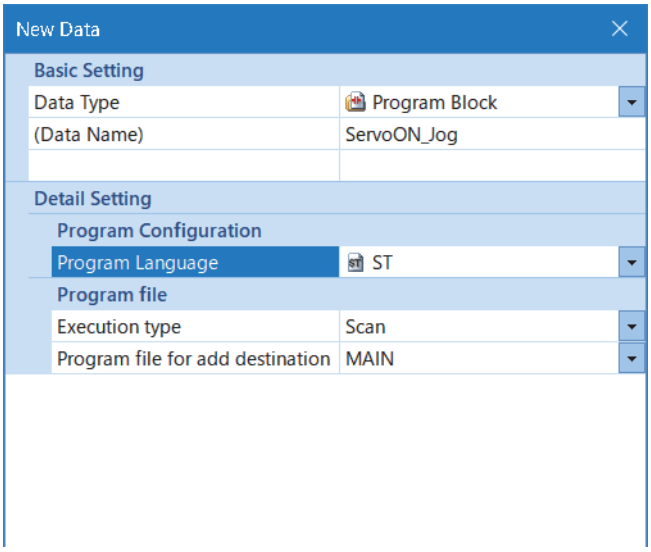
(1) I/O processing of motion operation

Point



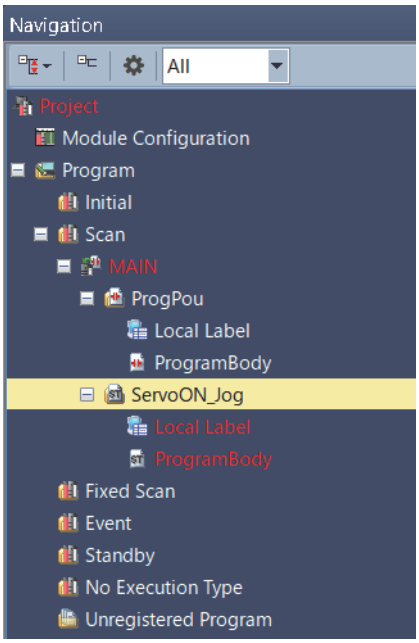
When applying the sample program to an actual system, ensure the applicability and check that it will not cause system control problems.
Consider and add interlock conditions according to the user's system.

6.1 Creation Procedure for Controller Programs



The engineering tool is used to create a program for a controller.

Creating a program block



1. In the navigation window of the engineering tool, right-click "Program" ⇨ the program execution type ("Scan" in this example), and select "Add New Data".

2. The "New Data" window is displayed. Set the data name, the program language, and the program file for add destination. Then, click the [OK] button. (Setting example: ServoON_Jog)

3. A program block is added to the navigation window.

Program execution types

The following table lists the five program execution types available.

Execution type	Description
Initial	This program is executed only once when the controller status is changed from the power-on to RUN or from STOP (PAUSE) to RUN.
Scan	This type of program is executed only once per scan. The execution starts from the next scan right after the initial execution type program is executed.
Fixed scan	This is an interrupt program which is executed at a specified time interval. Different from a normal interrupt program, this type of program does not require the interrupt pointer (I) or IRET instruction and is executed for each program file unit.
Event	This type of program starts execution when triggered by a specified event.
Standby	This type of program is executed only when its execution is requested.

To set the execution type, perform the following operations in the navigation window.

The set execution type will be applied to "Program Setting" in "CPU Parameter".

- Right-click on a target program in the navigation window, and select [Register Program] from the shortcut menu.
- Drag and drop the program onto the target execution type.

How to input an FB

This section describes the procedure for creating a program using the JOG operation FB (MCv_Jog) as an example.

Preparing labels

Prepare labels for input/output signals of the FB. This example uses labels for the Velocity, Acceleration, Deceleration, and Jerk inputs of MCv_Jog. When registering a new label, consider whether the label is registered as a global label or a local label.

Ex.

The labels for JOG command and JOG velocity are registered as global labels, considering that JOG velocity will be operated from an external device such as a GOT (HMI).

The labels for JOG acceleration, JOG deceleration, and JOG jerk are registered as local labels of the ServoON_Jog program created in Creating a program block (☞ Page 98 Creating a program block) since these labels are only used within this program.

For naming rules for labels, refer to the following.

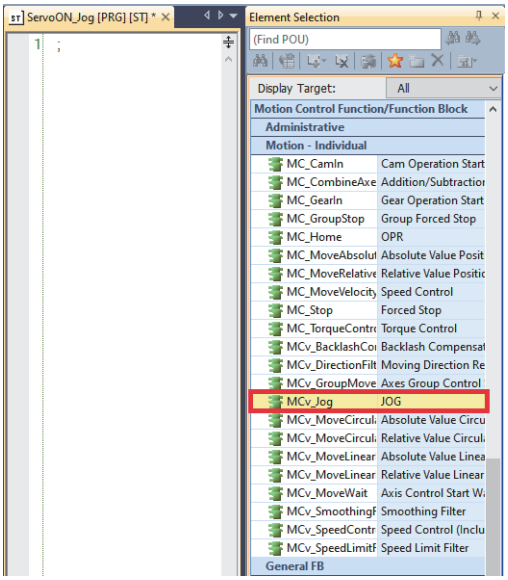
☞ Page 106 Naming rules for labels

■Global labels

	Label Name	Data Type		Class
1	G_bJogF1CMD	Bit	...	VAR_GLOBAL
2	G_bJogR1CMD	Bit	...	VAR_GLOBAL
3	G_bJog1Busy	Bit	...	VAR_GLOBAL
4	G_leJogVelocity	FLOAT [Double Precision]	...	VAR_GLOBAL
5			...	

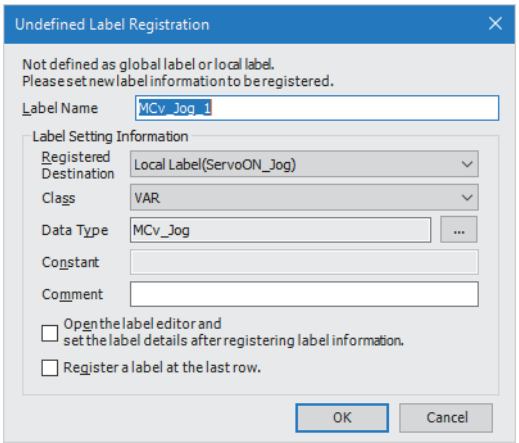
■Local labels

	Label Name	Data Type		Class
1	leJogAcceleration	FLOAT [Double Precision]	...	VAR
2	leJogDeceleration	FLOAT [Double Precision]	...	VAR
3	leJogJerk	FLOAT [Double Precision]	...	VAR
4			...	



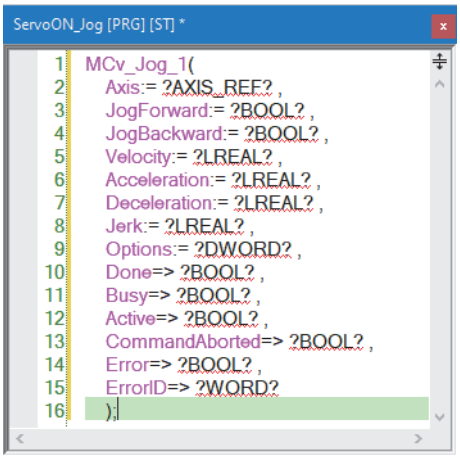
Inputting an FB

1. Click the [POU List] tab in the Element Selection window and select "Motion Control Function/Function Block" ⇨ "Administrative", "Motion - Individual", or "General FB" to display the FB library list.
The FB for JOG operation (MCv_Jog) is located in the "Motion - Individual" tree.



FBs are classified into the following three groups.

Group	Description
Administrative	A motion control FB that takes an axis or an axes group for the argument and does not change the axis status or the axes group status by execution (There are some exceptions.)
Motion - Individual	A motion control FB that takes an axis or an axes group for the argument and changes the axis status or the axes status by execution
General FB	A motion control FB that does not take an axis or an axes group for the argument



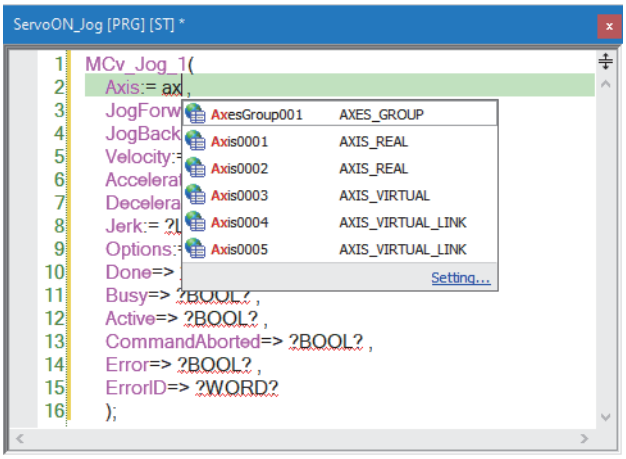
2. Drag and drop the FB to use (MCv_Jog) onto the program editor.

3. Enter the FB label name, registered destination, and comments if necessary, and click the [OK] button. This example uses all the initial settings.

4. Delete the leading semicolon because it is unnecessary. (Depending on the drag-and-drop position, there will be two semicolons at the end of the FB. In this case, delete one of them.)

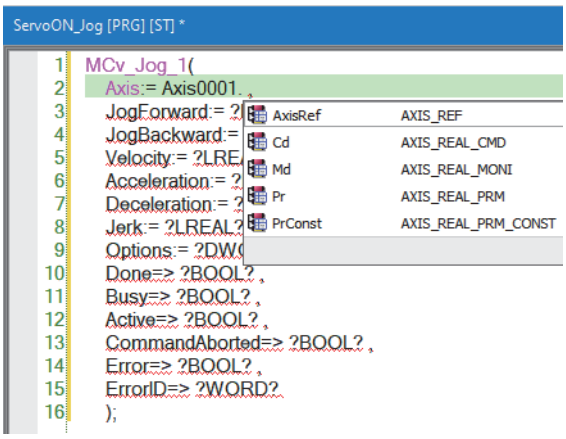
Point

From the menu of the engineering tool, select [Tool] ⇨ [Options] ⇨ [Program Editor] ⇨ [ST Editor] ⇨ [Edit Operation] ⇨ set [Vertically Align Arguments for Displaying Template] to "Yes" to automatically input line breaks and indents.



Inputting I/O signals

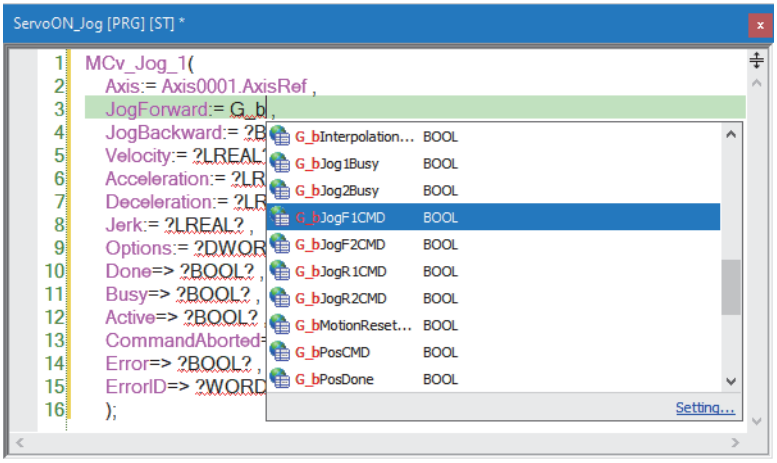
Rewrite strings such as ?AXIS_REF? and ?BOOL? to the labels.



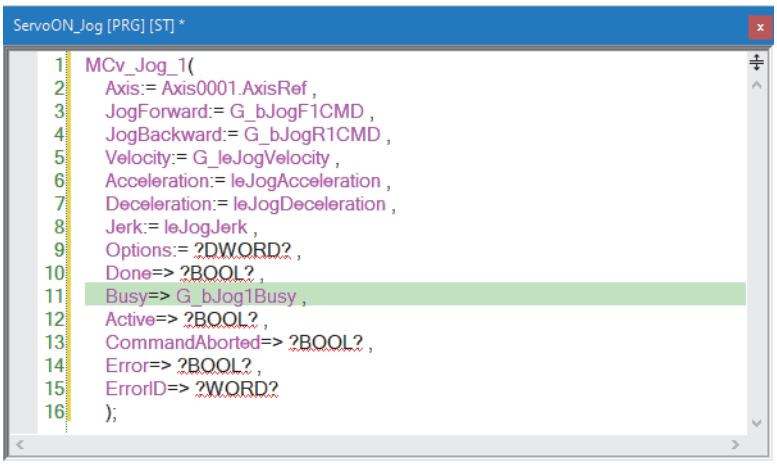
■AxisRef type structure

This section describes how to input the AxisRef type structure, which is axis information for axis 1, into the input variable Axis.

1. Enter "ax" in "Axis := " to display the registered labels.



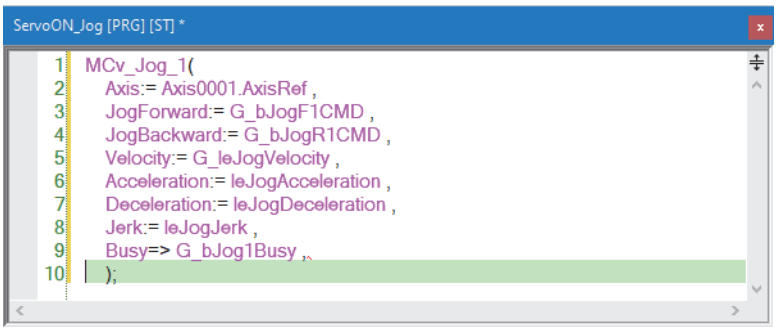
2. When "Axis0001" is selected and "." is entered, the structure members of Axis0001 will be displayed. Select "AxisRef".



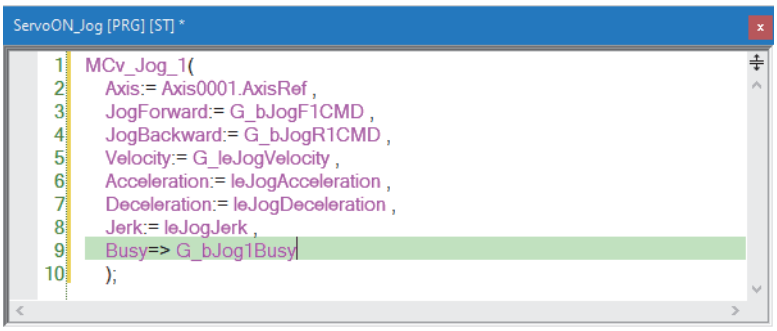
■Global label and local label

Enter the global label "G_bJogF1CMD" into the "JogForward" input.

1. When "G_b" is entered in "JogForward := ", the registered labels will be displayed. Select "G_bJogF1CMD".



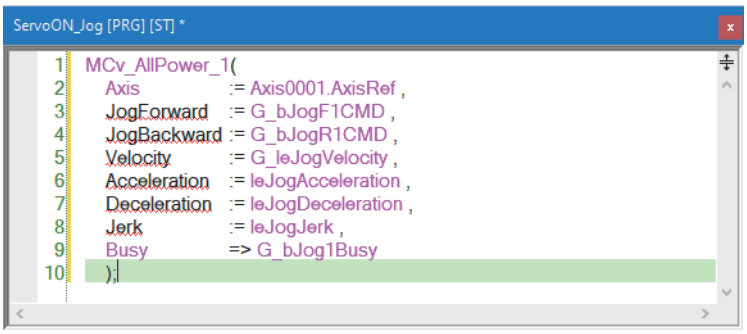
2. Using the same procedure, enter labels for the JogBackward, Velocity, Acceleration, Deceleration, Jerk, and Busy signals.



■Omitting I/O signals

Input signals using an initial value and input signals of unused FB can be omitted.

1. In the following example, the "Options" input remains unchanged from its initial value (0), and the output signals "Done", "Active", "CommandAborted", "Error", and "ErrorID" are deleted because they are not used.



2. Delete the "," at the end of the FB because it is unnecessary.

■Organizing format

Organize the program by adding comments and indents as necessary.

6.2 Labels

Naming rules for labels

This manual uses the following prefix rules for labels to distinguish their data type.

Data type		Value range	Prefix	
			Local	Global
Bit	BOOL	FALSE, TRUE	b	G_b
Word [unsigned]/bit string [16 bits]	WORD	0 to 65535	u	G_u
Double word [unsigned]/bit string [32 bits]	DWORD	0 to 4294967295	ud	G_ud
Word [signed]	INT	-32468 to 32767	w	G_w
Double word [signed]	DINT	-2147483648 to 2147483647	d	G_d
Single-precision real number	REAL	-2^{128} to -2^{-126}, 0, 2^{-126} to 2^{128}	e	G_e
Double-precision real number	LREAL	-2^{1024} to -2^{-1022}, 0, 2^{-1022} to 2^{1024}	le	G_le
Time	TIME	T#-24d20h31m23s648ms to T#24d20h31m23s647ms	tm	G_tm
Timer	TIMER	TIMER structure • S: contact • C: coil • N: current value	td	G_td

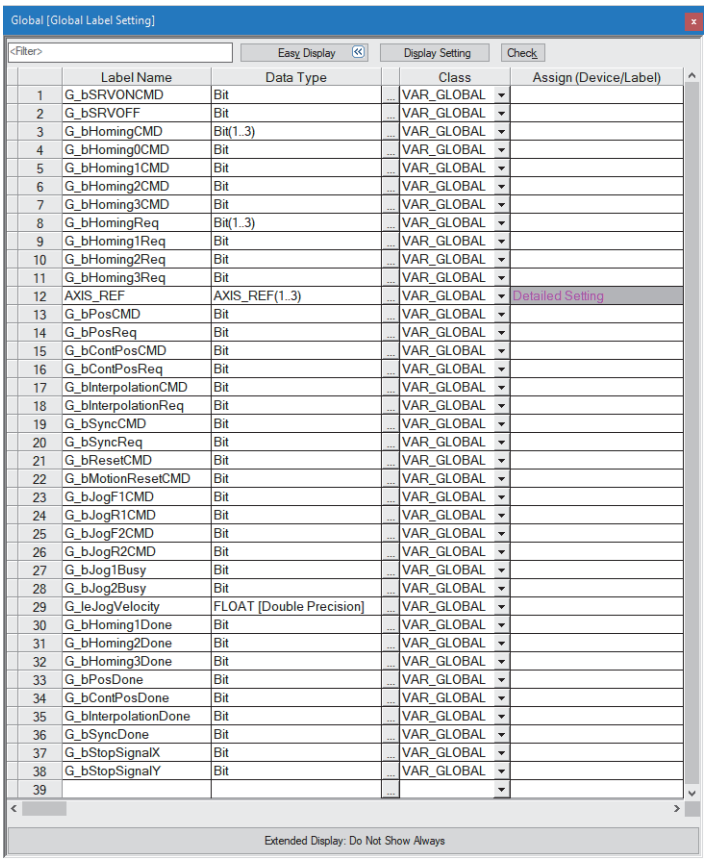
Ex.

For local labels

Data type	Label
Bit	bMoveCMD
Double-precision real number	lePosition
Word [signed]+array	wAxes[16]
Timer	tdTimer1

Ex.

For global labels



Data type	Label
Bit	G_bJogF1
Double-precision real number	G_leVelocity

Global label list

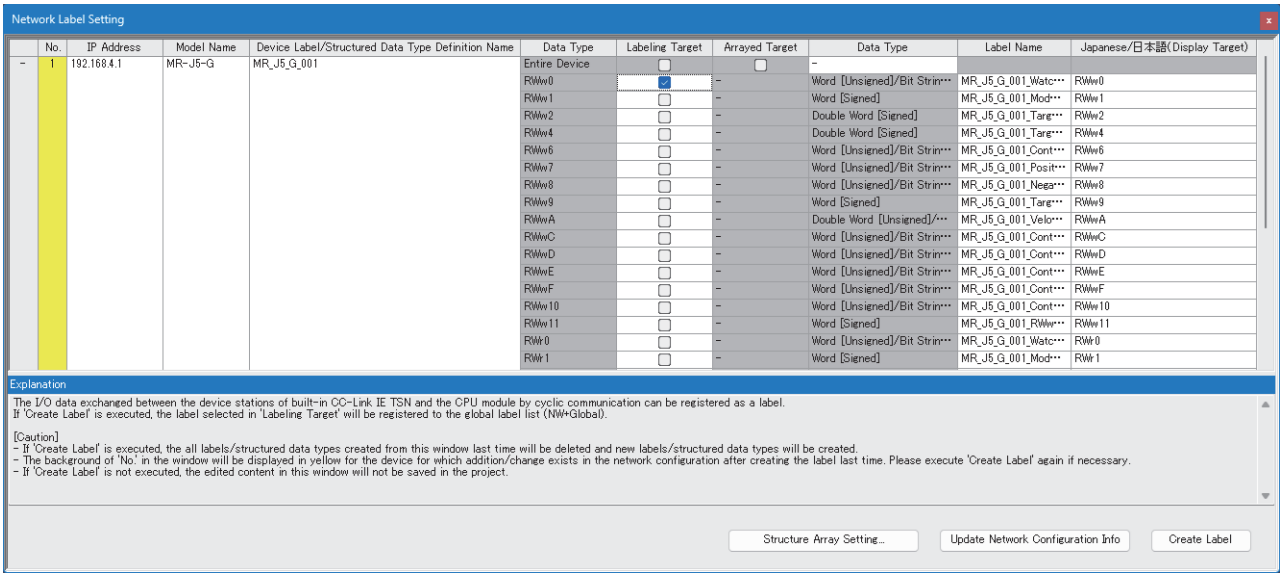
The following shows setting examples for the global labels in the sample program.
For the local labels, refer to each program.

Global label setting

The following table lists the global label settings.

	Label Name	Data Type	Class	Assign (Device/Label)
1	G_bSRVONCMD	Bit	VAR_GLOBAL	
2	G_bSRVOFF	Bit	VAR_GLOBAL	
3	G_bHomingCMD	Bit(1..3)	VAR_GLOBAL	
4	G_bHoming0CMD	Bit	VAR_GLOBAL	
5	G_bHoming1CMD	Bit	VAR_GLOBAL	
6	G_bHoming2CMD	Bit	VAR_GLOBAL	
7	G_bHoming3CMD	Bit	VAR_GLOBAL	
8	G_bHomingReq	Bit(1..3)	VAR_GLOBAL	
9	G_bHoming1Req	Bit	VAR_GLOBAL	
10	G_bHoming2Req	Bit	VAR_GLOBAL	
11	G_bHoming3Req	Bit	VAR_GLOBAL	
12	AXIS_REF	AXIS_REF(1..3)	VAR_GLOBAL	Detailed Setting
13	G_bPosCMD	Bit	VAR_GLOBAL	
14	G_bPosReq	Bit	VAR_GLOBAL	
15	G_bContPosCMD	Bit	VAR_GLOBAL	
16	G_bContPosReq	Bit	VAR_GLOBAL	
17	G_bInterpolationCMD	Bit	VAR_GLOBAL	
18	G_bInterpolationReq	Bit	VAR_GLOBAL	
19	G_bSyncCMD	Bit	VAR_GLOBAL	
20	G_bSyncReq	Bit	VAR_GLOBAL	
21	G_bResetCMD	Bit	VAR_GLOBAL	
22	G_bMotionResetCMD	Bit	VAR_GLOBAL	
23	G_bJogF1CMD	Bit	VAR_GLOBAL	
24	G_bJogR1CMD	Bit	VAR_GLOBAL	
25	G_bJogF2CMD	Bit	VAR_GLOBAL	
26	G_bJogR2CMD	Bit	VAR_GLOBAL	
27	G_bJog1Busy	Bit	VAR_GLOBAL	
28	G_bJog2Busy	Bit	VAR_GLOBAL	
29	G_leJogVelocity	FLOAT [Double Precision]	VAR_GLOBAL	
30	G_bHoming1Done	Bit	VAR_GLOBAL	
31	G_bHoming2Done	Bit	VAR_GLOBAL	
32	G_bHoming3Done	Bit	VAR_GLOBAL	
33	G_bPosDone	Bit	VAR_GLOBAL	
34	G_bContPosDone	Bit	VAR_GLOBAL	
35	G_bInterpolationDone	Bit	VAR_GLOBAL	
36	G_bSyncDone	Bit	VAR_GLOBAL	
37	G_bStopSignalX	Bit	VAR_GLOBAL	
38	G_bStopSignalY	Bit	VAR_GLOBAL	
39				

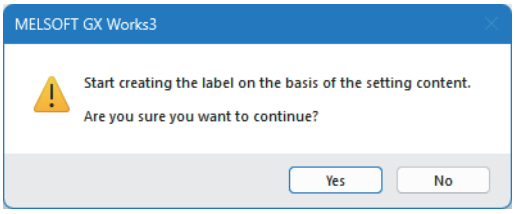
Network labels



Creating a network label enables label access to other modules on the network that are not on the same base unit.
Network labels target remote stations and are registered as global labels.

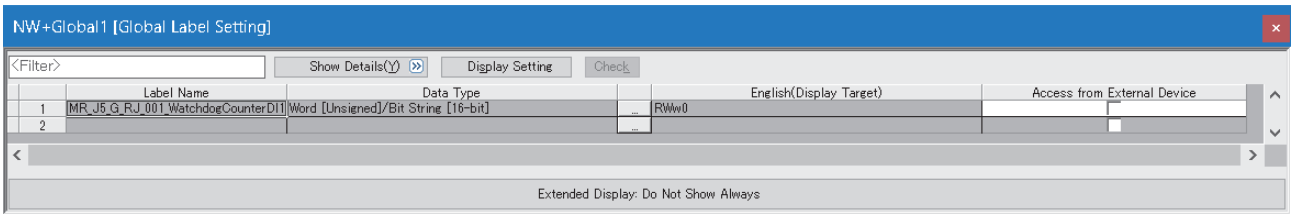
■Creation procedure for network labels

Operating procedure



1. Display the "Network Label Setting" window, and insert a check in "Labeling Target" for "Data Type" to be labeled.

Navigation window ⇨ "Parameter" ⇨ Controller ⇨ "Module Parameter (Port 1/2: CC-Link IE TSN)" ⇨ "Network Label Setting"



2. Click the [Create Label] button.

3. Click the [Yes] button.

4. A list of the created network labels is displayed in Global Label.

Navigation window ⇨ "Label" ⇨ "Global Label" ⇨ "NW+Global1"

Point

- Set the remote station in advance in the "CC-Link IE TSN Configuration" window.
- Right-click in the "Network Label Setting" window and execute "Add Prefix" or "Delete Prefix" to add or delete a device label to/from the label names.

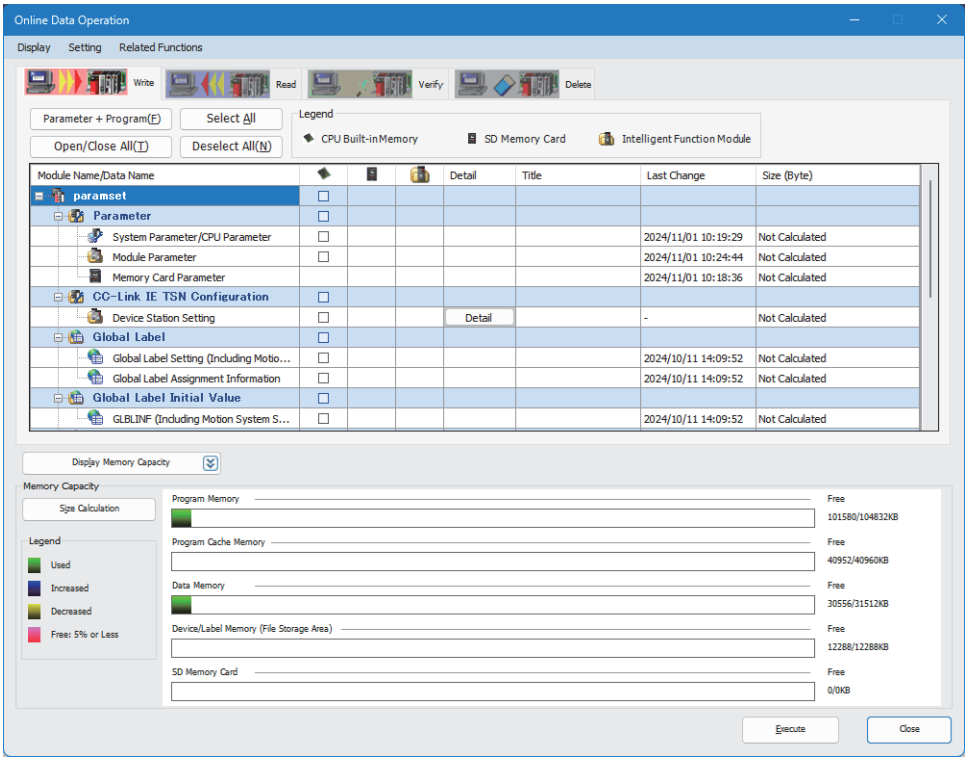
Precautions

- When the network number or network configuration setting has been changed, open the "Network Label Setting" window again or click the [Update Network Configuration Info] button and then the [Create Label] button.
- Network labels will be refreshed regardless of whether the network label checkbox is selected in the network configuration setting. Therefore, the network labels that are already created will be refreshed even if the network label checkbox in the network configuration setting is not selected. If no network label is used, delete the network labels.
- When using the network labels assigned to RY and another RY in the same word boundary, use network label.

6.3 Motion Program Example

For program examples to use motion control, refer to the following.

☞ Page 1203 PROGRAM EXAMPLES



6.4 Checking Operation

Conversion and writing of programs

Write the program to the controller.

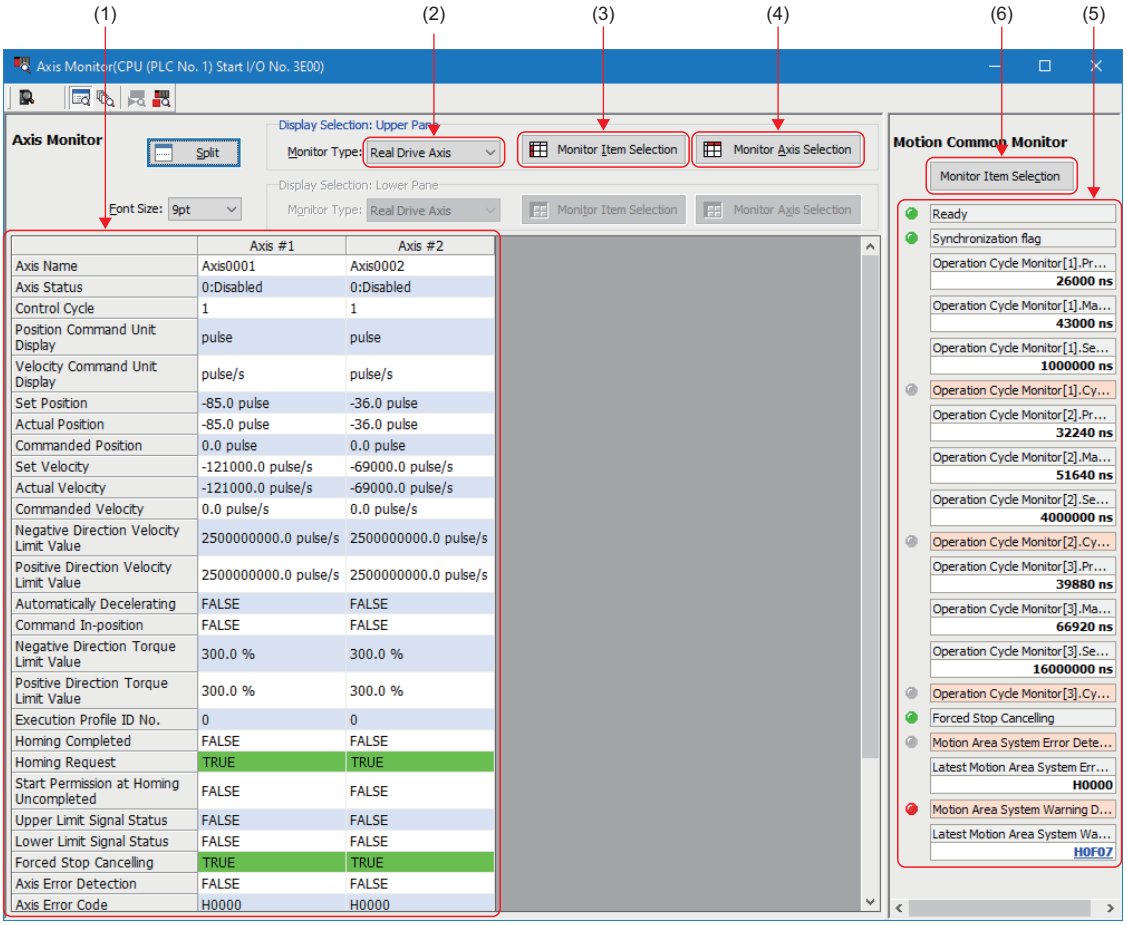
Operating procedure

1. After creating the programs, select [Convert] ⇨ [Rebuild All] from the menu to convert all the programs.
2. Check that no error occurs after executing "Rebuild All". Select [Online] ⇨ [Write to PLC] in the menu, and write the programs to the controller.

Axis monitor

The axis monitor displays the current values and the error codes of all axes in operation all at once.
Users can check the current values and whether any error occurs during the operation.

Displaying the axis monitor window



The axis monitor window can be displayed by following the steps below.

Operating procedure

1. Select [Online] ⇨ [Motion Monitor] ⇨ [Axis Monitor] from the menu bar of the engineering tool.

Displayed contents

The following contents are displayed on the axis monitor.

No.	Name	Description
(1)	Axis monitor display items	The monitor items for each axis selected in monitor type are displayed.
(2)	Monitor type	The axis type to monitor can be selected.
(3)	Monitor item selection	Add/delete items to monitor in the axis monitor display items.
(4)	Monitor axis selection	Add/delete axes to monitor in the axis monitor display items.
(5)	System monitor display items	The system monitor items are displayed.
(6)	Monitor item selection	Add/delete items to monitor in the system monitor display items.

Program monitor

The program monitor enables the user to check the current status of the program in execution on the program editor.

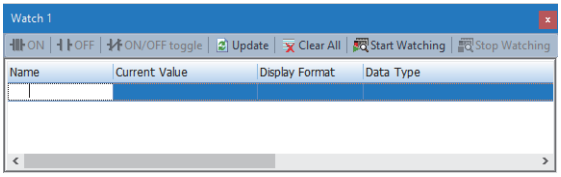
Displaying the program monitor window

The program monitor window can be displayed by following the steps below.

- Select [Online] ⇨ [Monitor] ⇨ [Start Monitoring] from the menu bar of the engineering tool.
- Click the "Start Monitoring (All Windows)" icon on the tool bar of the engineering tool.

Watch

The watch function enables the user to check the current values of registered devices and labels.
Register the devices and labels to be monitored to a watch window.



Displaying the watch window

Select [View] ⇨ [Docking Window] ⇨ [Watch 1] to [Watch 4] from the menu in the engineering tool.

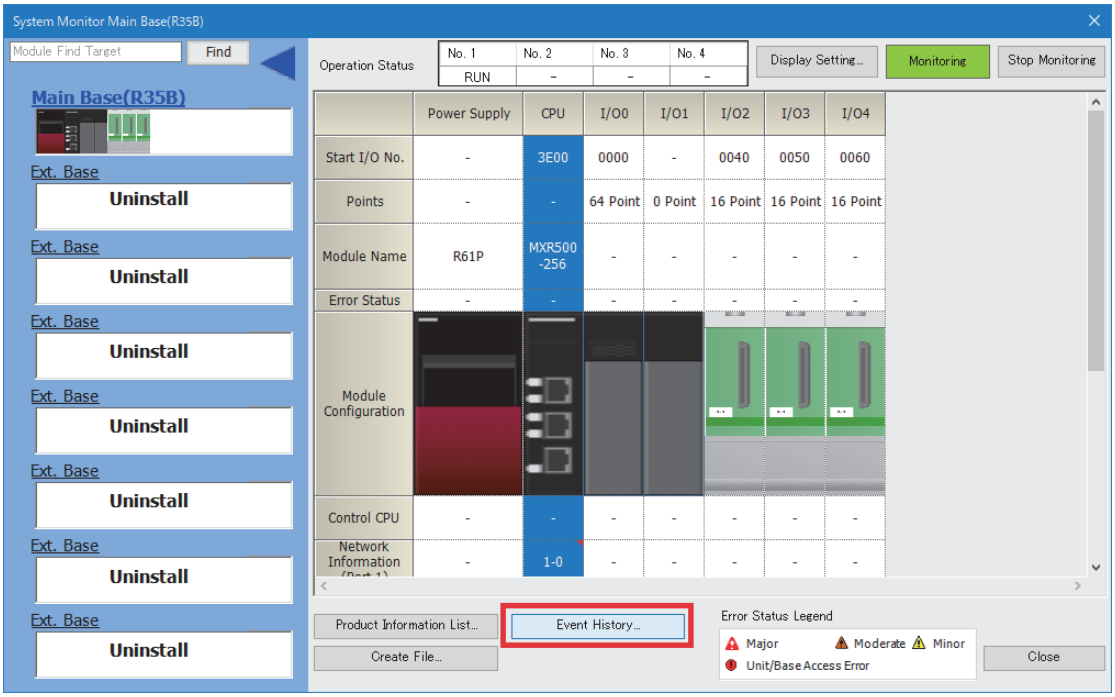
Registration of devices/labels/structures to a watch window

Register devices/labels/structures by using the following methods.

- Select the label or structure to register on the program editor, right-click the label or structure, and select [Register to Watch Window] ⇨ [Watch 1] to [Watch 4].
- Enter the device number, label, or structure in the "Name" column of a watch window.

Watching start

Select [Online] ⇨ [Watch] ⇨ [Start Watching] from the menu in the engineering tool.



Changing current values

Directly enter a value in "Current Value" during watching.
To switch the on/off (TRUE/FALSE) of bit devices or bit type labels, select the row and double-click it with Shift pressed, or select the row and press both Shift and Enter.

Event history

To check the event history, click [Diagnostics] ⇨ [System Monitor] in the menu of the engineering tool, and then click "Event History" on the "System Monitor" window. If an error occurs, check the details of the error.

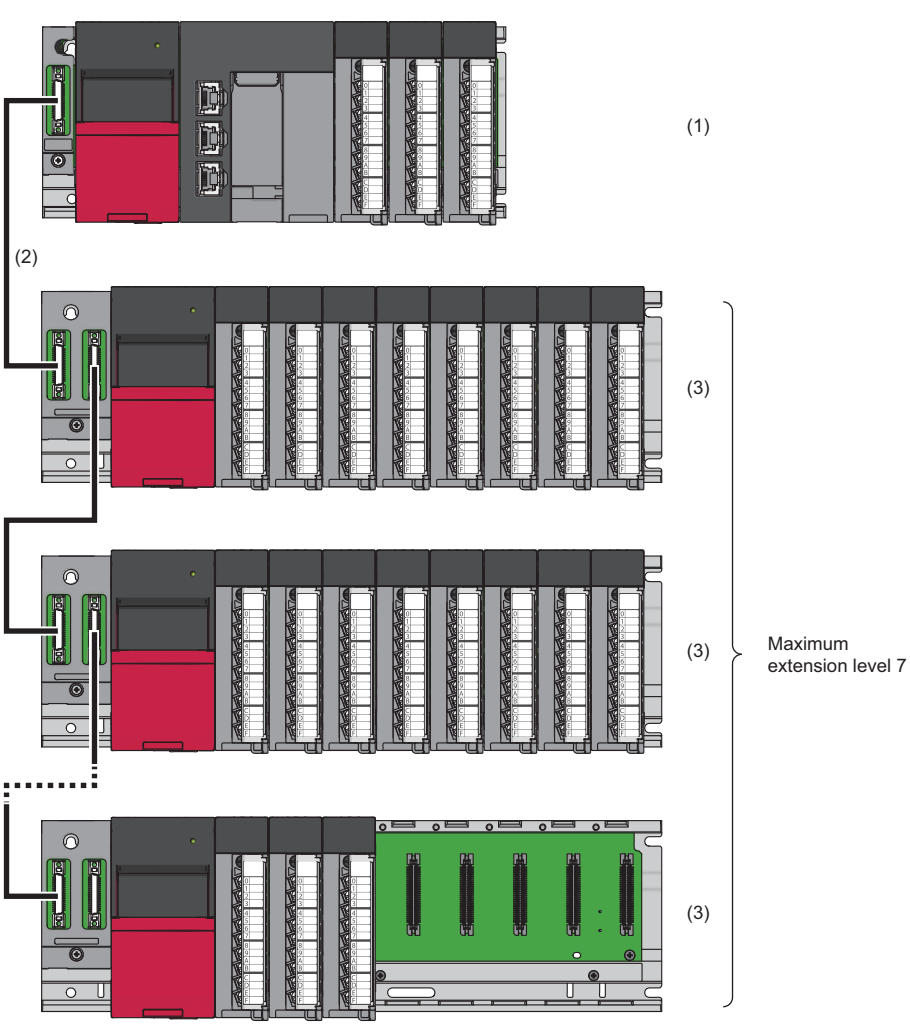
The error occurrence time in the event history of the controller synchronizes with those recorded. Check the error details of the event history together with the data in the servo amplifier.

MEMO

PART 4 SYSTEM CONFIGURATION

This part consists of the following chapters.

7 CONTROLLER SYSTEM CONFIGURATION

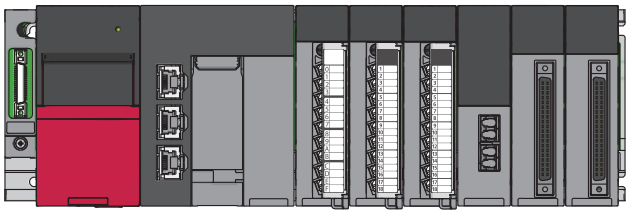


8 ASSIGNMENT FOR MODULES

7 CONTROLLER SYSTEM CONFIGURATION

This chapter describes the system configuration of a controller.

7.1 Overall Configuration



A power supply module is mounted on the power supply slot located on the left end of a main base unit, and a controller is mounted on the CPU slot located on the right side of the power supply slot. Modules other than the power supply module are mounted on the slots located on the right side of the CPU slot.

(1) Main base unit
(2) Extension cable
(3) Extension base unit

Single CPU system

This single CPU system controls I/O modules and intelligent function modules with a single controller mounted on a main base unit.

7.2 Lists of Configuration Devices

The following tables show the system configuration devices of a controller.

For the modules that are not described in this section, refer to the manuals for each module used.

Manuals for each module used

Main base unit

Item	Model
Main base unit	R33B, R35B, R38B, R312B

Extension base unit and extension cable

Item	Model
Extension base unit	R65B, R68B, R612B
Extended temperature range extension base unit	R610B-HT
Extension cable	RC06B, RC12B, RC30B, RC50B, RC100B

Power supply module

Item	Model
Power supply module	R61P, R62P*1, R63P, R64P, R69P
Redundant power supply module	R63RP, R64RP, R69RP

*1 When the MXR500-128 or MXR500-256 is used, the R62P cannot be used in combination with the main base unit because the current consumption exceeds the rated output current of the R62P. When the MXR300-16, MXR300-32, or MXR300-64 is used, the R62P can only be used in combination with the R33B or R35B.

Point

- For the internal current consumption of the controller, check the performance specifications. (Page 210 Hardware specifications)
- For the rated output current of the power supply module, refer to the following.

MELSEC iQ-R Module Configuration Manual

SD memory card

Item	Model
SD memory card	NZ1MEM-2GBSD, NZ1MEM-4GBSD, NZ1MEM-8GBSD, NZ1MEM-16GBSD

Battery

Item	Model
Battery	FX3U-32BL

I/O module

Item	Model
AC input module	RX10
	RX10-TS
	RX28
DC input module	RX40C7, RX41C4, RX42C4
	RX40C7-TS, RX41C4-TS, RX70C4, RX71C4, RX72C4
DC high-speed input module	RX40PC6H, RX40NC6H
	RX41C6HS, RX61C6HS
Input module with diagnostic functions	RX40NC6B*1
Contact output module	RY10R2
	RY10R2-TS
	RY18R2A
Triac output module	RY20S6
Transistor output module	RY40NT5P, RY41NT2P, RY42NT2P, RY40PT5P, RY41PT1P, RY42PT1P
	RY40NT5P-TS, RY41NT2P-TS, RY40PT5P-TS, RY41PT1P-TS
Transistor high-speed output module	RY41NT2H, RY41PT2H
Output module with diagnostic functions	RY40PT5B*1
I/O combined module	RH42C4NT2P

*1 SIL2 mode is not supported.

Analog module

Item	Model
Analog-digital converter module	R60AD4, R60ADI8, R60ADV8
High speed analog-digital converter module	R60ADH4
Channel isolated analog-digital converter module	R60AD8-G*1, R60AD16-G
Channel isolated analog-digital converter module (with signal conditioning function)	R60AD6-DG
Digital-analog converter module	R60DA4, R60DAI8, R60DAV8
High speed digital-analog converter module	R60DAH4
Channel isolated digital-analog converter module	R60DA8-G, R60DA16-G

*1 SIL2 mode is not supported.

Temperature input module, temperature control module

Item	Model
Channel isolated thermocouple input module	R60TD8-G
Channel isolated RTD input module	R60RD8-G
Temperature control module	R60TCTRT2TT2, R60TCTRT2TT2BW, R60TCRT4, R60TCRT4BW
	R60TCTRT2TT2-TS, R60TCRT4-TS

High-speed counter, isolated pulse input, flexible high-speed I/O control modules

Item	Model
High-speed counter module	RD62P2, RD62D2, RD62P2E
Channel isolated pulse input module	RD60P8-G
Flexible high-speed I/O control module	RD40PD01

Positioning module

Item	Model
Positioning module	RD75P2, RD75P4, RD75D2, RD75D4

Information module

Item	Model
Ethernet interface module with built-in CC-Link IE	RJ71EN71
Serial communication module	RJ71C24, RJ71C24-R2, RJ71C24-R4
MES interface module*1	RD81MES96N
GP-IB interface module	RJ71GB91

*1 Before using, check the versions of the controller and engineering tool used. (☞ Page 2196 Added or Enhanced Functions and Supported Versions)

Network module

Item	Model
CC-Link IE TSN-equipped module	RJ71GN11-T2
	RJ71GN11-SX
	RJ71GN11-EIP
CC-Link IE Controller Network module	RJ71GP21-SX
	RJ71GP21S-SX
CC-Link IE Field Network module	RJ71GF11-T2
CC-Link system master/local module	RJ61BT11
AnyWireASLINK master module	RJ51AW12AL
DeviceNet master/slave module	RJ71DN91
CANopen module*1	RJ71CN91
BACnet module	RJ71BAC96

*1 The parameters cannot be set with the configuration tool. Set them with the buffer memory.

Energy measuring module

Item	Model
Energy measuring module	RE81WH

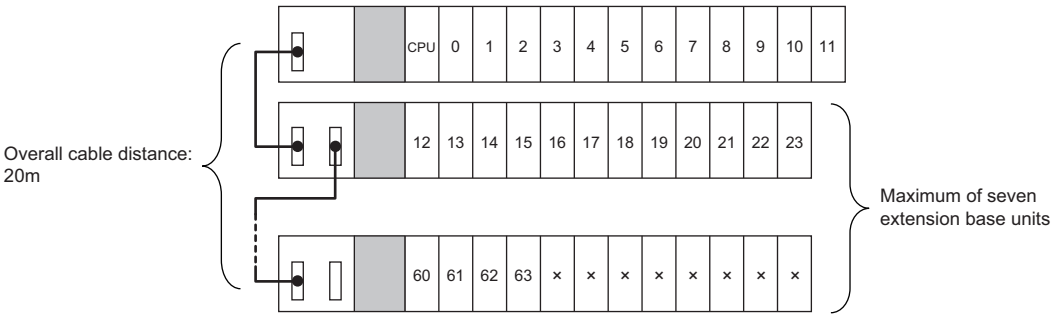
Blank cover module

Item	Model
Blank cover module	RG60

GOT

Item		Model
GOT2000	GT27 model	GT27□□-□
	GT25 model	GT25□□-□
	GT21 model*1	GT21□□-□
SoftGOT		GT SoftGOT2000 (Multi)

*1 This model cannot be connected by using the motion function because it does not support global labels and 64-bit labels.



7.3 System Configuration Specifications

This section provides an overview of the system configuration of a controller.

Controller

The following table shows the system configuration when a controller is mounted on the CPU slot of a main base unit.

Item	Description
Maximum number of mountable modules	62
Maximum number of extension base units	7
Overall extension cable distance	20m

- Shaded areas are for the power supply modules.
- "CPU" is the CPU slot, and the numbers are slot numbers.
- Modules cannot be mounted on the slots marked ×.

Modules having restrictions on the number of mountable modules

This section describes modules having restrictions on the number of mountable modules.

MELSEC iQ-R series modules

The following table shows the restrictions when a controller is mounted on the CPU slot of a main base unit.

Item	Model	Maximum number of mountable modules
CC-Link IE TSN-equipped module	• RJ71GN11-T2 • RJ71GN11-SX • RJ71GN11-EIP	8*2*3
CC-Link IE Controller Network-equipped module	• RJ71GP21-SX • RJ71GP21S-SX • RJ71EN71*1	8
CC-Link IE Field Network-equipped master/local module	• RJ71GF11-T2 • RJ71EN71*1	8*2*3
CC-Link system master/local module	• RJ61BT11	8*2

*1 When using ports as CC-Link IE Controller Network and CC-Link IE Field Network, do not exceed the maximum number for each connection. When using ports as Ethernet, there is no restriction on the number of mountable modules.

*2 There is no restriction on the number of mountable modules when parameters are set using the dedicated instruction after "Program" in "Module Parameter" is selected.

*3 Indicates the number of modules including a controller.

7.4 Applicable Software

The following table lists software that can be used.

Item	Function	Application	Version
GX Works3	Software for a system design, programming, debug, and maintenance of a programmable controller	Used for setting the controller.	"1.115V" or later
CPU Module Logging Configuration Tool	Software for data logging setting and maintenance	Used for logging.	"1.166Y" or later
GX LogViewer	An easy-to-use tool for displaying and analyzing large-capacity data collected by modules with the data collection function		"1.166Y" or later
CommDTM (Communication DTM) for IO-Link module	A software module for configuring the settings of communication with field devices, from the personal computer via the IO-Link master	Used for setting the CC-Link IE Field Network remote IO-Link module.	"1.05F" or later
MR Configurator2	A configuration tool for the servo amplifier	Used for setting the motion function.	"1.165X" or later
OPC UA data collector	A software for data collection compatible with Edgecross	Used for executing the collection function, read function, and write function for the device connected to the OPC UA server.	"1.06G" or later

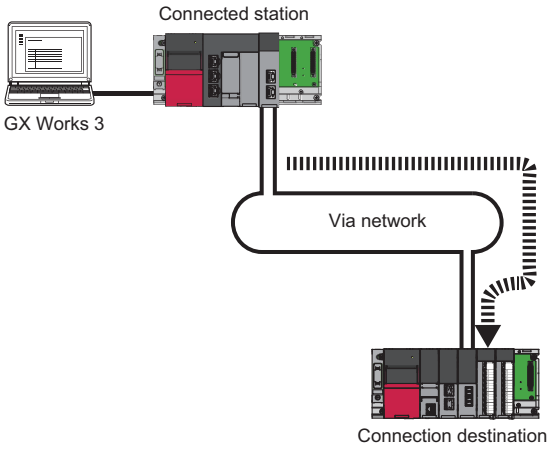
7.5 Access Range

This section describes the range when accessed via a network from an engineering tool connected to the controller or CPU module.

Point

The following networks can be accessed.

- Ethernet
- Serial communication
- CC-Link IE TSN
- CC-Link IE Field
- CC-Link IE Control
- CC-Link



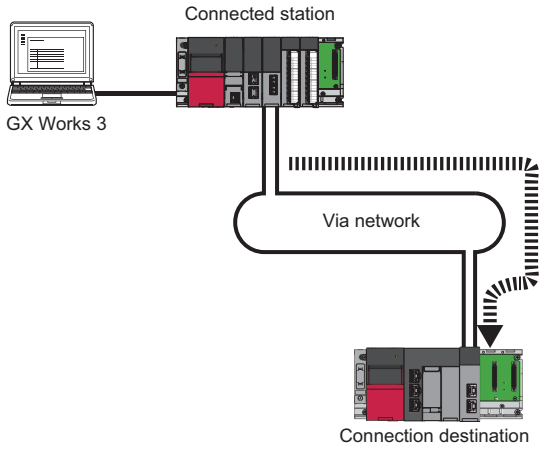
When the connected station is a controller

The engineering tool connected to the controller can access the following connection destinations via the network.

Ex.

Below is a configuration example using the following modules.

- Controller
- MELSEC iQ-R series CPU module
- Remote head module (RJ72GF15-T2)



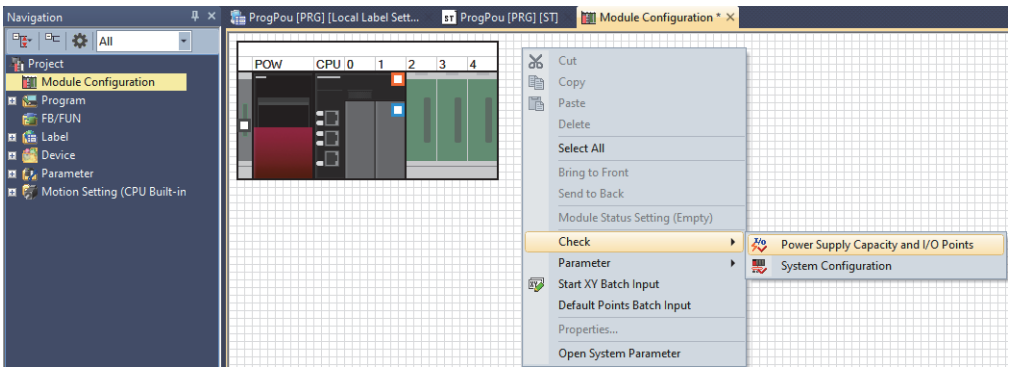
When the connection destination is a controller

The engineering tool connected to the following connection stations can access the controller via the network.

Ex.

Below is a configuration example using the following modules.

- Controller
- MELSEC iQ-R series CPU module
- Remote head module (RJ72GF15-T2)



7.6 Precautions for System Configuration

This section describes precautions for configuring a system.

Consideration for internal current consumption

Configure the system so that the internal current consumption of the entire system will be equal to or less than the rated output current of the power supply module.

The internal current consumption can be checked by using the engineering tool as follows.

The following window shows the check result.

Result of Power Supply Capacity and I/O Points Check

Base/C...	Slot	Model Name	Consumption Current	Total Consumption Current	Total Voltage Drop	Total I/O Points
R35B	-	R35B	0.58A	4.88A / 6.5A	-	112 Point / 4096 Point
	[Power S...	R61P	-			
	[CPU]	MXR500-256	4.3A			
	[0]	Network/Motion	-			
	[1]	Empty (3 Slot(s) Occupy)	-			

Restrictions for use together with MELSEC iQ-R series modules

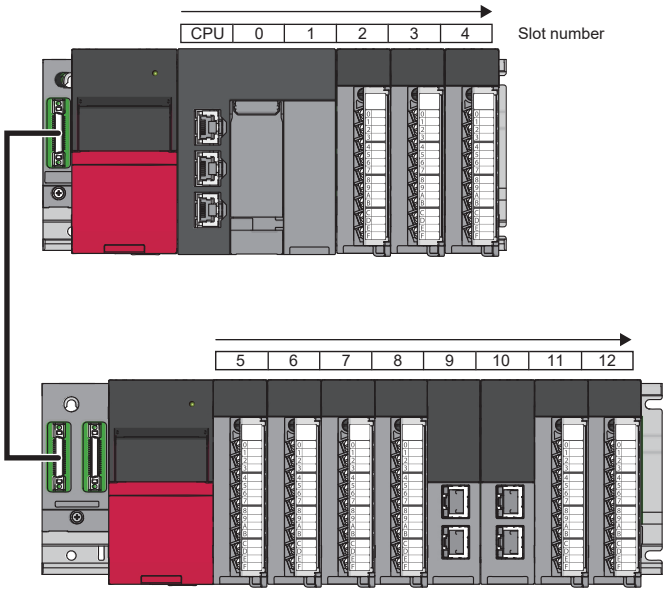
For restrictions other than those described below, refer to the manual for each module.

Model	Function	Restriction
RJ71EN71	File transfer function (FTP server)	The following subcommands usable for the quote command are not supported. • passwd-rd • passwd-wr • password-lock • password-unlock • pm-write
	SLMP	The following commands are not supported. • Remote Password Lock (command: 1631) • Remote Password Unlock (command: 1630)
RJ71C24(-R2/R4)	MC protocol	The following commands are not supported. • Remote Password Lock (command: 1631) • Remote Password Unlock (command: 1630)
• RJ71GN11-T2 • RJ71GN11-SX • RJ71GN11-EIP	SLMP	The following commands are not supported. • Remote Password Lock (command: 1631) • Remote Password Unlock (command: 1630)

8 ASSIGNMENT FOR MODULES

This chapter describes how to assign slot numbers and I/O numbers to modules.
These assignments can be set by placing the same modules in the actual system on the "Module Configuration" window using the engineering tool.
These assignments can also be set by reading system parameters or actual system configuration. (GX Works3 Operating Manual)
The following table lists the setting availability on the module configuration window or system parameters for each item.

Item	Module configuration window	System parameter
Base unit model	○	○
Power supply module model	○	○
Extension cable model	○	○
Module model	○	○
Module order	○	○
I/O numbers of modules (☞ Page 133 I/O Numbers of Modules)	○	○
Module status setting (☞ Page 139 Module status setting)	○	○
Number of points of an empty slot (☞ Page 138 I/O numbers of an empty slot)	○	○
Number of slots on a base unit (☞ Page 130 Setting the number of slots)	×	○
Number of points of a module	×	○



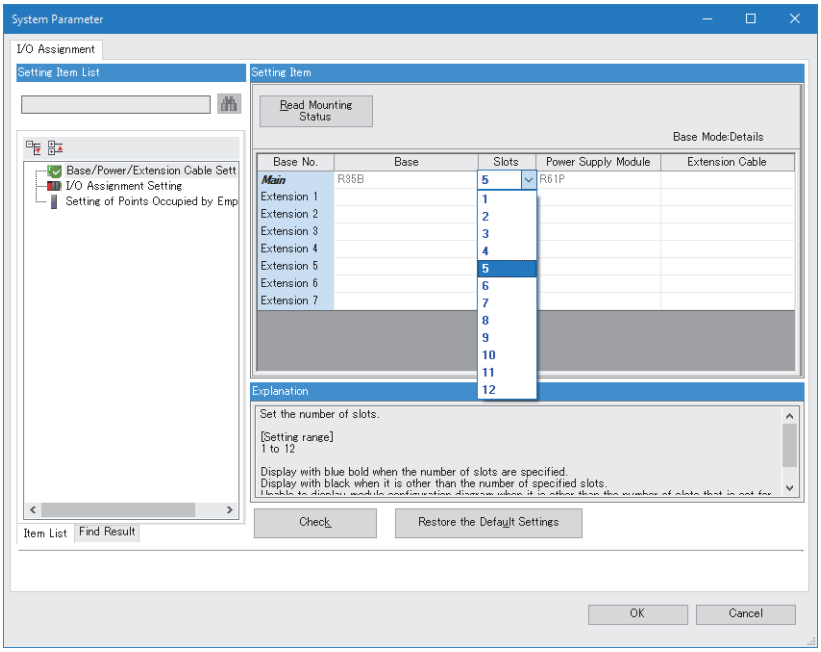
Point

Set assignments either on the module configuration window or in the system parameters depending on the application.

- Module configuration window: To use information unique to each module, such as the number of occupied points, as it is
- System parameter: To change the number of slots on a base unit or the number of occupied points of a module

8.1 Slot Numbers on a Base Unit

Slot numbers are sequentially assigned starting from the slot on the right side of the CPU slot.
When extension base units are connected, slot numbers are assigned to the main base unit first, and successively to the extension base units (1st level to 7th level).



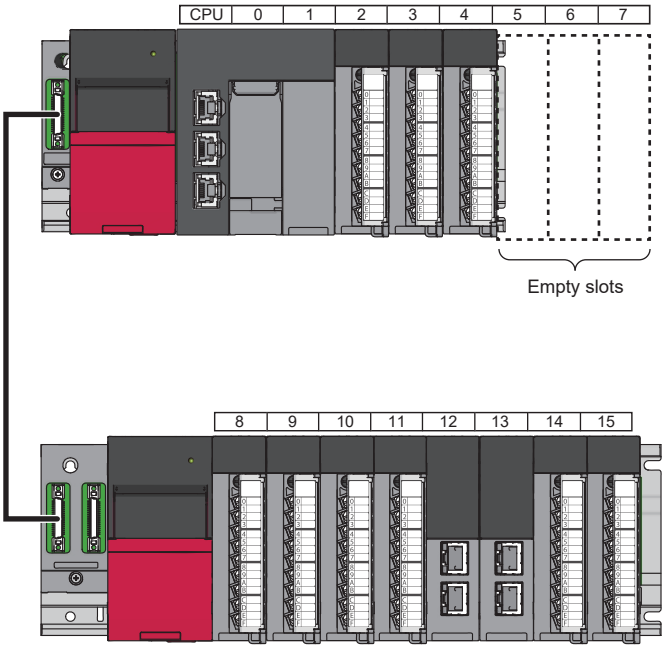
If a module which occupies two slots is mounted, slot numbers for two modules are assigned.

Setting the number of slots

The number of slots for each base unit can be set within the range of 1 to 12. Set the number of slots for the following purposes.

- To secure slots so that the base unit can be changed to the one having the different number of slots in the future
- To keep the same number of slots even after the base unit used in the existing system is changed

Navigation window ⇨ [System Parameter] ⇨ [I/O Assignment] ⇨ [Base/Power/Extension Cable Setting]



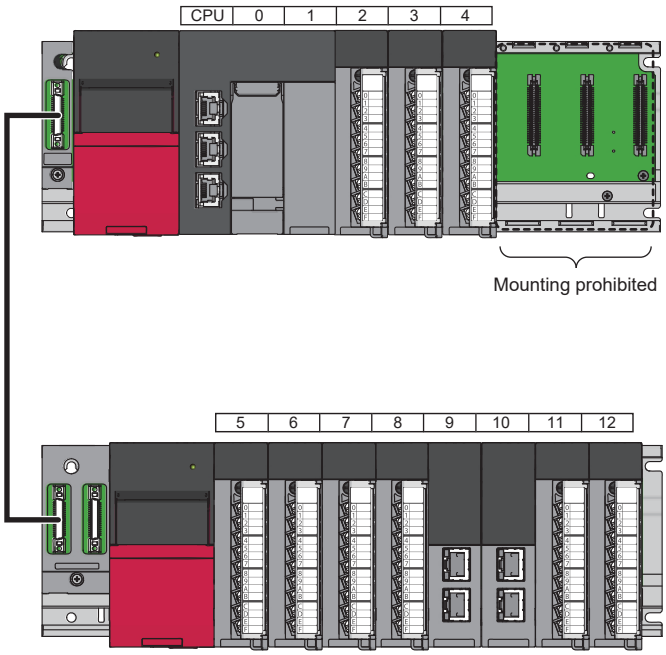
■When the number of set slots is more than the number of actual slots

Slots corresponding to the set number are occupied, where the slots exceeding the actual number are regarded as empty slots.

Ex.

When the number of slots is set to eight for the base unit with five slots, three slots are regarded as empty slots.

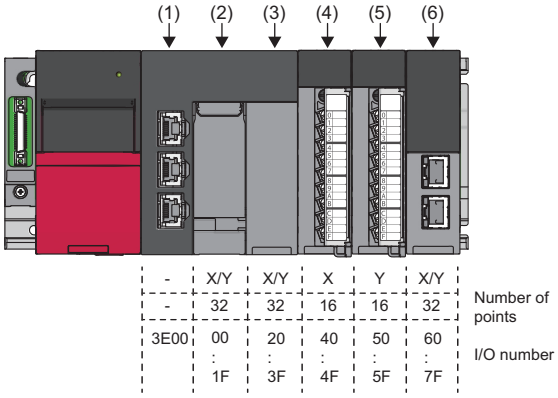
Point



The number of points for empty slots can be changed on the "Module Configuration" window, or in "Setting of Points Occupied by Empty Slot" of the [I/O Assignment] tab on the "System Parameter" window. (☞ Page 138 I/O numbers of an empty slot)

■When the number of set slots is less than the number of actual slots

Slots corresponding to the set number are occupied, where slots that are out of the set range are prohibited from mounting a module, and the slot number is not assigned.



Ex.

When the number of slots is set to five for the base unit with eight slots, three slots will be use-prohibited.

8.2 I/O Numbers of Modules

An I/O number is a number (hexadecimal) assigned to I/O modules and intelligent function modules to communicate data with the controller. On/off data are classified into two types: input and output, and the symbol, "X" for input, and "Y" for output, is added in front of the I/O number.

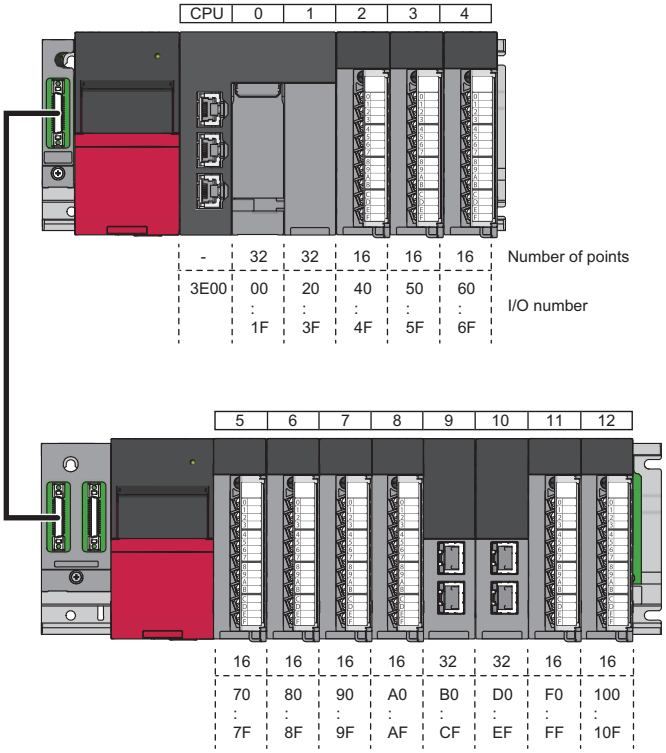
(1) CPU function part of the controller
(2) CC-Link IE TSN function part of the controller
(3) Motion function part of the controller
(4) Input module
(5) Output module
(6)Intelligent function module

Point

- The CPU function part performs sequence control and Ethernet communications through the Ethernet port (P3).
- In the CC-Link IE TSN function part, CC-Link IE TSN and Ethernet communications are performed through the CC-Link IE TSN port (P1, P2).
- For details on how to specify the buffer memory areas of each function part, refer to the following.

☞ Page 375 Buffer memory specification method

Automatic setting of I/O numbers



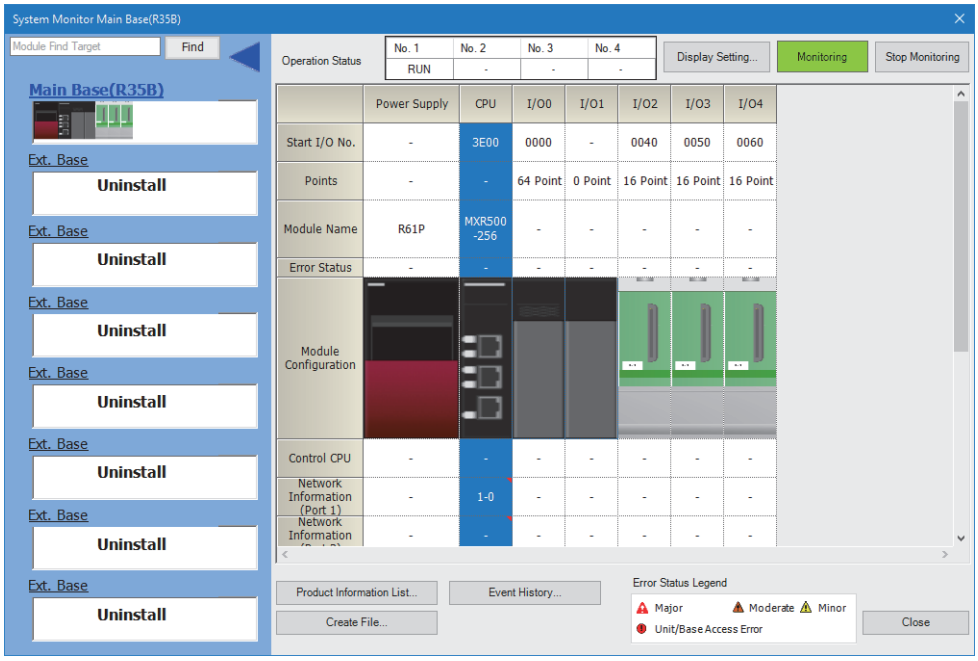
I/O numbers are automatically assigned in sequential order. On the main base unit, the I/O number assignment starts with the module on the right side of the controller.

On the extension base unit, the I/O number starts from the next number of the last I/O number on the main base unit.

Each slot on the base unit occupies I/O numbers corresponding to the number of points of the module mounted.

Ex.

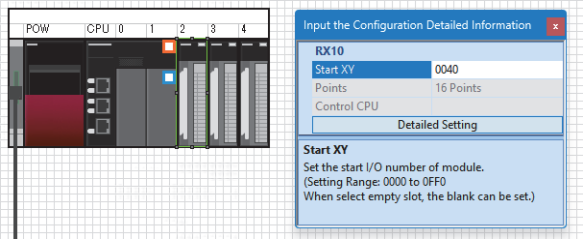
When the I/O number starts from 40H in sequential order



Upon placing a module on the "Module Configuration" window using the engineering tool, the I/O numbers are automatically assigned according to the number of occupied points of the module.

Even though the mounting position of the module is changed, the I/O numbers once assigned remain unchanged.

Point



The mounted modules and their I/O numbers can be checked on the "System Monitor" window using the engineering tool. (GX Works3 Operating Manual)

Changing I/O numbers

Upon placing a module on the "Module Configuration" window, the I/O numbers are automatically assigned according to the number of occupied points of the module. The assigned I/O numbers, however, can be changed for each module.

- To eliminate the need of modification due to an overlap of I/O numbers after the module is changed to a module having a different number of occupied points
- To reduce the program modifications when using an existing program by assigning modules according to the I/O numbers that have already been used in the program

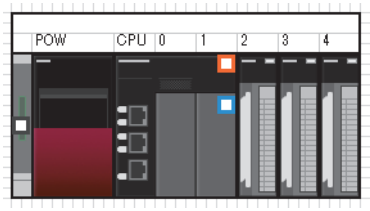
Point

The I/O number of the CC-Link IE TSN function part can also be changed.
If the I/O number of the CC-Link IE TSN function part is changed, 32 points from the next I/O number for which 32 points from "Start XY" assigned to the CC-Link IE TSN function part are occupied will automatically be assigned to the I/O number of the motion function part.

■Precautions

- Set the same model as the one actually mounted.
- The module that is not set as actually mounted denies access.
- The number of I/O points of a module can be changed in "I/O Assignment Setting" of the [I/O Assignment] tab on the "System Parameter" window.
- If the number of I/O points set in the parameters differs from that of the module actually mounted, the number of I/O points will be as follows:

Setting	Operation	Remarks
The number of I/O points set in the parameters is less than that of the module actually mounted.	The available number of points for the mounted I/O modules is reduced to the set number of points.	Intelligent function modules do not permit the setting of a fewer number of I/O points.
The number of I/O points set in the parameters is more than that of the module actually mounted.	The number of I/O points exceeding the actual number of I/O points is not used in the mounted I/O modules and intelligent function modules.	—

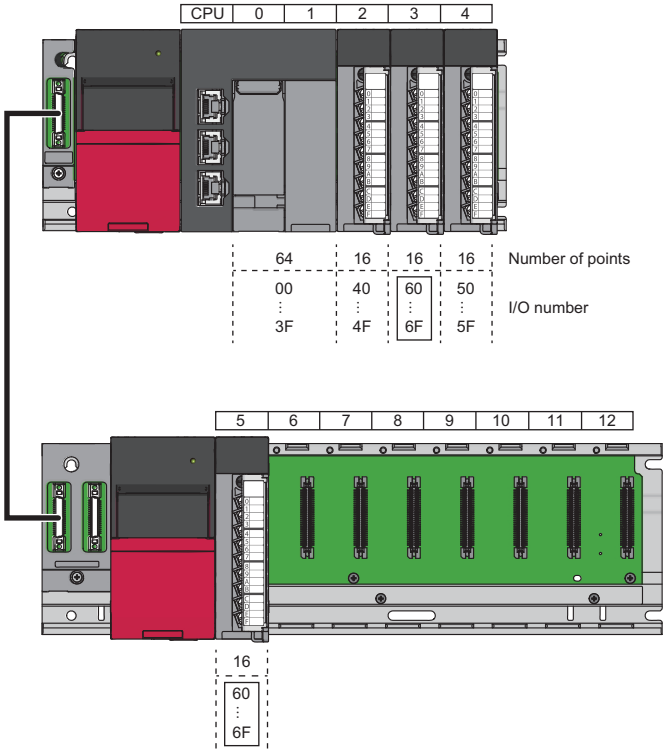


- Set same modules as in the actual system on the "Module Configuration" window. Because the settings of the engineering tool control the module operation, a setting that is different from the actual configuration may result in unintended operation.
- When changing the default I/O numbers, setting the I/O numbers to all the modules is recommended. I/O numbers of a module that is not set in the engineering tool are assigned following the I/O numbers of the module already set, which may cause an overlap of I/O numbers.

Ex.

I/O numbers overlap as a result of setting the I/O numbers up to the module on slot No.4.

• I/O numbers set by using the engineering tool

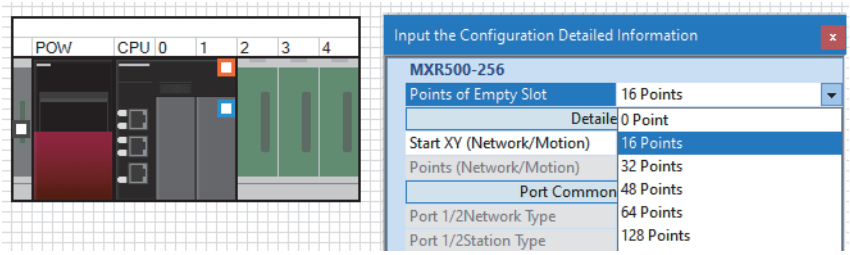


Set the start I/O number 60 to the module on slot No.3, and 50 to the module on slot No.4.

Slot	Module Name	Module Status Setting	Points	Start XY
Main				
CPU	MXR500-256(Host Station)			3E00
CPU	Network/Motion		64 Points	0000
CPU	3 Slots Occupy [Empty]		0 Points	
2(0-2)	RX10	No Setting	16 Points	0040
3(0-3)	RX10	No Setting	16 Points	0050
4(0-4)	RX10	No Setting	16 Points	0060

• I/O numbers in the actual system

I/O numbers of the module on slot No.5, which is not set in the engineering tool, are assigned following the I/O numbers of the module on slot No.4. This results in an overlap of I/O numbers.



Set the I/O numbers of the module on slot No.5 in the parameter so that they do not overlap.

Slot	Module Name	Module Status Setting	Points	Start XY
Main				
CPU	MXR500-256(Host Station)			3E00
CPU	Network/Motion		64 Points	0000
CPU	3 Slots Occupy [Empty]		0 Points	
2(0-2)	RX10	No Setting	16 Points	0040
3(0-3)	RX10	No Setting	16 Points	0050
4(0-4)	RX10	No Setting	16 Points	0060
Extension 1				
5(1-0)	RX10	No Setting	16 Points	0070

• To set the module reserved for future use, or when an already set module is not to be mounted, perform the module status setting. (☞ Page 139 Module status setting)

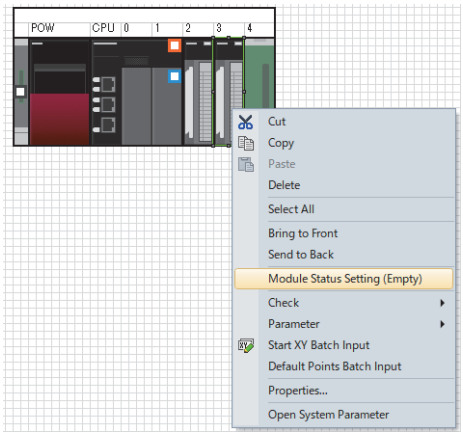
I/O numbers of an empty slot

An empty slot is a slot where a module is not mounted, and occupies 16 points by default.
I/O numbers and the number of points can be set to empty slots for future use.
The number of I/O points can be changed for all empty slots at once by selecting the controller on the "Module Configuration" window as shown below.

Module status setting

The module status setting makes it possible to set the module status such as reserved status and disabled status, interpreting a configured module in the engineering tool as an empty slot.

The following table summarizes the application of the module status setting.

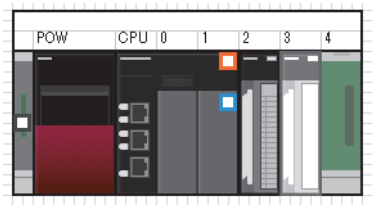


Status	Application
Reserved status	• To operate the system while a module is allocated in the engineering tool but not actually mounted • To reserve the I/O numbers of a module for future use
Disabled status	• To disable operation of an actually mounted module

The change of the parameter settings is not reflected in the module where the module status setting has been performed.

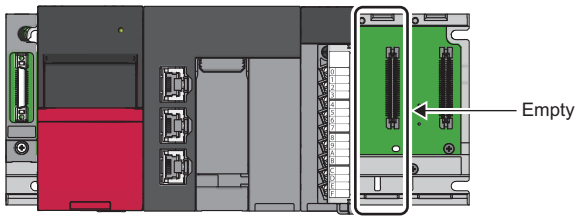
In addition, the following operations have no effect on the module where the module status setting has been performed:

- Setting a remote password
- Executing a program that accesses the set target module



Set the module status as shown below. (GX Works3 Operating Manual)

Ex.

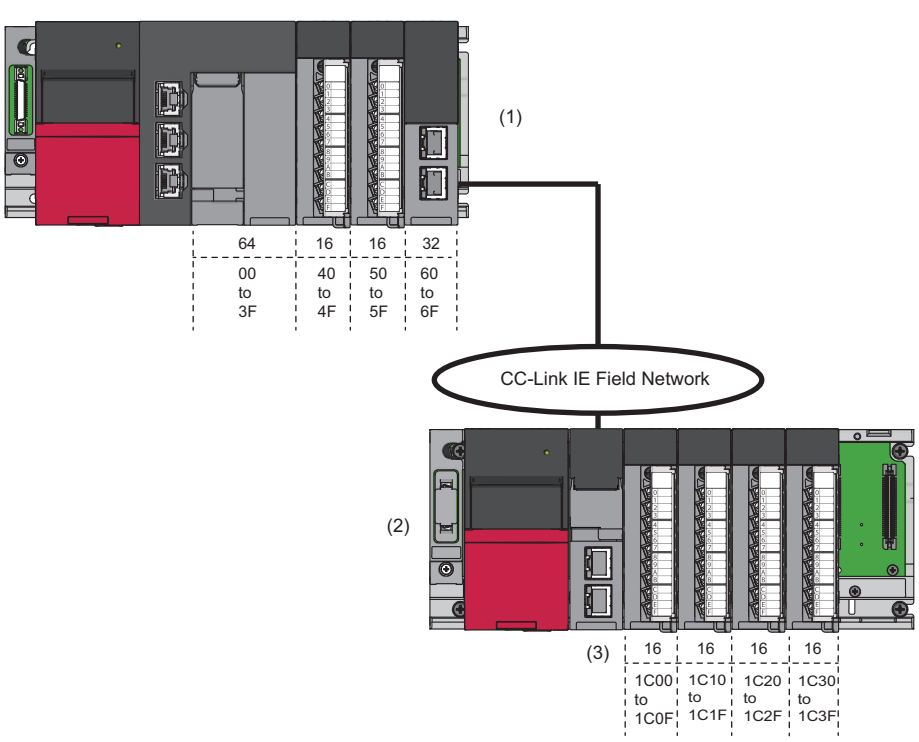


To operate the system while a module is allocated in the engineering tool but not actually mounted

- Module configuration window

When the module status is set, the set target module is high-lighted, and regarded as an empty slot.

- Actual system



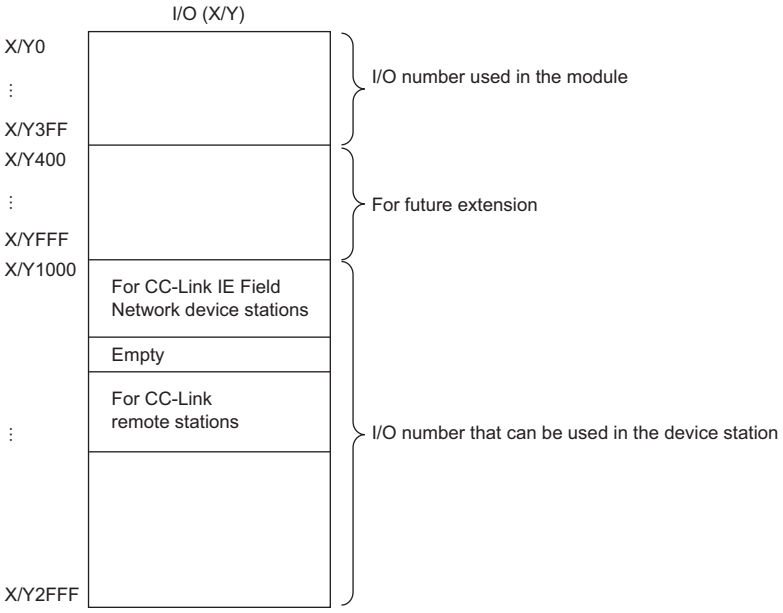
Writing the module configuration to the controllers allows operation even without mounting modules actually.

Assigning I/O numbers in the device station

Network systems such as CC-Link IE Field Network can be controlled by assigning input "X" and output "Y", which are the devices of the controller, to the I/O modules and intelligent function modules in the device station.

Ex.

Controlling a module connected to the remote head module on CC-Link IE Field Network



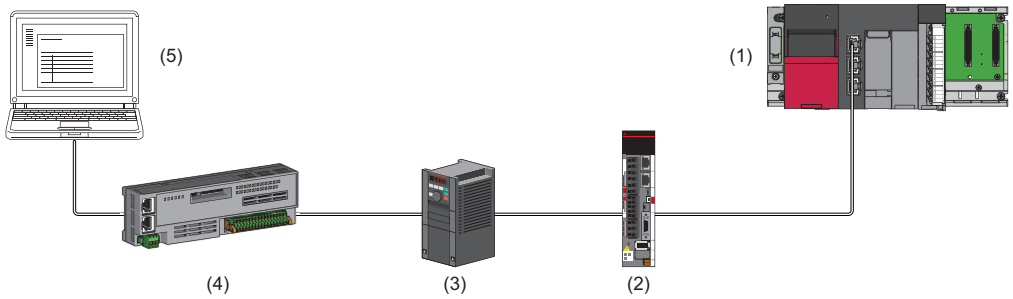
■Available I/O numbers

In the device station, assign the I/O numbers following the I/O numbers assigned to the modules in the master station.

■Precautions

- The same I/O numbers cannot be used for the refresh destination (device on the controller side) on CC-Link IE Field Network and for the CC-Link remote station.
- When intending to connect more I/O modules and intelligent function modules to the controller later, reserve I/O numbers for modules to be added.

PART 5 COMMUNICATION WITH EQUIPMENT



This part consists of the following chapters.

9 CC-Link IE TSN SYSTEM CONFIGURATION

10 Ethernet SYSTEM CONFIGURATION

9 CC-Link IE TSN SYSTEM CONFIGURATION

The controller becomes a master station and controls the entire network.
CC-Link IE TSN is configured using Ethernet cables. (☞ Page 62 Ethernet cable)
Use the port for CC-Link IE TSN. When only one of the connectors is used, either P1 or P2 is applicable.
For the specifications of connectable devices, refer to the manual for each device used.

(1) Controller
(2) Drive unit
(3) Inverter device
(4) Remote I/O module and other modules
(5) Ethernet device

Restriction

Among CC-Link IE TSN compatible devices, the following modules cannot be connected to the controller.

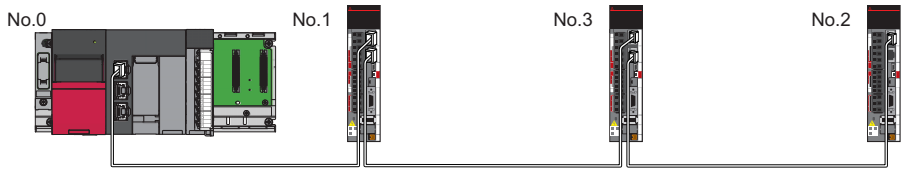
- CC-Link IE TSN-CC-Link IE Field Network bridge module: NZ2GN-GFB
- CC-Link IE TSN-AnyWireASLINK bridge module: NZ2AW1GNAL
- CC-Link IE TSN FPGA module: NZ2GN2S-D41P01, NZ2GN2S-D41D01, NZ2GN2S-D41PD02

Restriction

If a parameter where the following settings in CC-Link IE TSN are set is written to the controller, an error occurs.

- Ring topology*1
- Local station setting*2
- "LB Setting" and "LW Setting"*3
- Multicast*4
- Setting values 1 to 32 for "Transient Transmission Group No."*5

*1 If a parameter where the ring topology is set is written to the controller, an error (error code 3A32H) occurs.
*2 If a parameter where a local station is set is written to the controller, an error (error code 3A6EH) occurs.
*3 If a parameter where "LB Setting" and "LW Setting" are set is written to the controller, an error (error code 3A6EH) occurs.
*4 If a parameter where the multicast is set is written to the controller, an error (error code 3A6EH) occurs.
*5 If a parameter where any of the setting values 1 to 32 is set for "Transient Transmission Group No." is written to the controller, an error (error code 3A6EH) occurs.



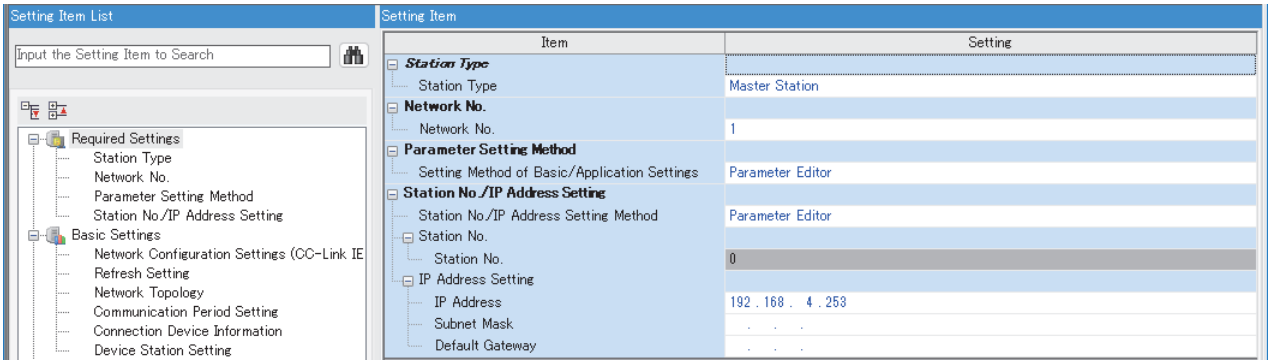
System configuration list

The following table lists the system configuration references by connection device.

Connection device	Reference
Modules on CC-Link IE TSN (CC-Link IE TSN Class B only), Ethernet devices	Page 171 Structure with CC-Link IE TSN Class B Devices Only
Modules on CC-Link IE TSN (mixture of CC-Link IE TSN Class B/A or Class A only), Ethernet devices	Page 178 Structure with CC-Link IE TSN Class B/A Devices
Modules on CC-Link IE TSN, modules on CC-Link IE Field Network, Ethernet devices	Page 188 Structure of the CC-Link IE TSN and CC-Link IE Field Network
Modules on CC-Link IE TSN (protocol version 2.0/1.0 mixed), Ethernet devices	Page 2129 Configuration with CC-Link IE TSN Class B/A devices (Protocol version 2.0/1.0)
Modules on CC-Link IE TSN (protocol version 1.0 only), Ethernet devices	Page 2132 Configuration with CC-Link IE TSN Class B/A devices (Protocol version 1.0 only)

Point

Modules can be connected in any order regardless of the station number. A No.☐ shown in the figure below represents a station number.



Precautions

A dedicated industrial switch (CC-Link IE TSN Class B certified) may be required depending on the parameter settings or the network topology used to connect modules on CC-Link IE TSN.

9.1 Required Settings

Set the parameters such as the IP address of the controller.

Navigation window ⇨ [Parameter] ⇨ Controller model ⇨ [Module Parameter (Port 1/2: CC-Link IE TSN)] ⇨ [Module Parameter (CC-Link IE TSN)] ⇨ [Required Settings]

Item	Description	Reference
Station Type	Set the station type of the controller.	Page 144 Station Type
Network No.	Set the network number of the own station of the controller.	Page 145 Network No.
Parameter Setting Method	Select the setting methods for "Basic Settings" and "Application Settings".	Page 145 Parameter Setting Method
Station No./IP Address Setting	Set the parameters such as the station number and IP address of the own station of the controller.	Page 146 Station No./IP Address Setting

Station Type

Set the station type of the controller.

"Module Parameter (CC-Link IE TSN)" ⇨ "Required Settings" ⇨ "Station Type"

Item	Description	Setting range
Station Type	The controller is used as a master station. Only one master station can be set in a network.	Master Station

Network No.

Set the network number of the own station of the controller.

"Module Parameter (CC-Link IE TSN)" ⇨ "Required Settings" ⇨ "Network No."

Item	Description	Setting range
Network No.	Set the network number of the controller.	1 to 239 (Default: 1)

Precautions

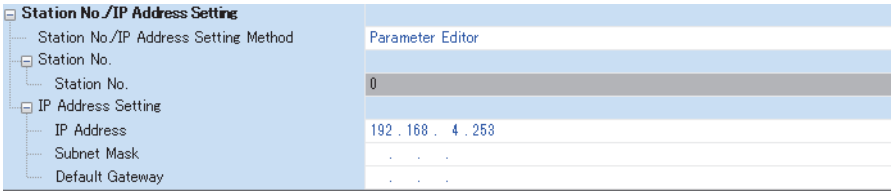
Set a network number that does not overlap any other network numbers.

In particular, when using an Ethernet port of the controller at default, the IP address is 192.168.3.39 and the network number is the third octet of the IP address, thus 3. Because setting the network number of the port for CC-Link IE TSN to 3 causes an overlap, set another network number.

Parameter Setting Method

Select the method for setting "Basic Settings" and "Application Settings" items.

"Module Parameter (CC-Link IE TSN)" ⇨ "Required Settings" ⇨ "Parameter Setting Method"

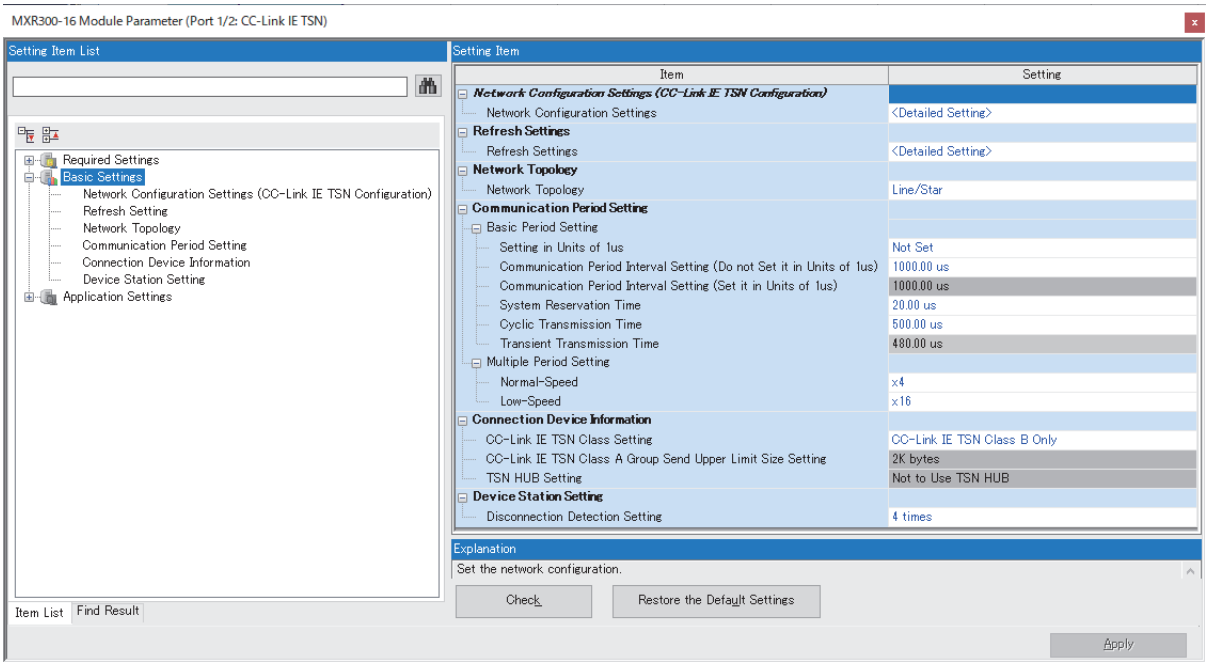


Item	Description	Setting range
Setting Method of Basic/ Application Settings	■Parameter Editor Select this item to set the parameter using the engineering tool. The following are advantages. • All parameters can be easily set in the window without creating a program for setting. • The data will be automatically transferred from SB, SW, and link devices of the CC-Link IE TSN function part to the devices or module label of the CPU function part.	Parameter Editor

Station No./IP Address Setting

Set the parameters such as the station number and IP address of the own station of the controller.

"Module Parameter (CC-Link IE TSN)" ⇨ "Required Settings" ⇨ "Station No./IP Address Setting"



Item	Description	Setting range
Station No./IP Address Setting Method	The method is fixed to "Parameter Editor".	Parameter Editor
Station No.	The master station is fixed to station No.0.	0
IP Address	Set the IP address of the own station. Set an IP address different from those used in other stations. Do not set the following values. • The third and fourth octets are all 0 or all 1. • The host address bits are all 0 or all 1 • Reserved address Also, set the IP address to be in a different segment from the IP address set for the Ethernet port.	0.0.0.1 to 223.255.255.254 (Default: 192.168.4.253)
Subnet Mask	Set the subnet mask. Set the same value for the master station and device station. If the subnet mask is empty, the address class (class A, class B, class C) is determined from the setting of "IP Address", and operation is done with the subnet mask according to the address class. The subnet mask for each class is as follows. • Class A: 255.0.0.0 • Class B: 255.255.0.0 • Class C: 255.255.255.0 The IP address for each class is as follows. • Class A: 0.x.x.x to 127.x.x.x • Class B: 128.x.x.x to 191.x.x.x • Class C: 192.x.x.x to 223.x.x.x The host address for each class is the 0 section shown below. • Class A: 255.0.0.0 • Class B: 255.255.0.0 • Class C: 255.255.255.0	• Empty • 0.0.0.1 to 255.255.255.255 (Default: Empty)
Default Gateway	Set the default gateway.	• Empty • 0.0.0.1 to 223.255.255.254 (Default: Empty)

9.2 Basic Settings

Configure settings such as the refresh setting of the controller.

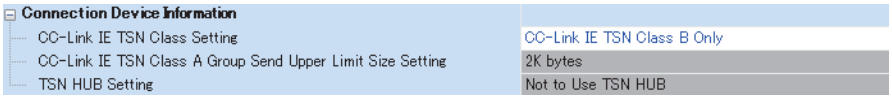
Navigation window ⇨ [Parameter] ⇨ Controller model ⇨ [Module Parameter (Port 1/2: CC-Link IE TSN)] ⇨ [Module Parameter (CC-Link IE TSN)] ⇨ [Basic Settings]

Item	Description	Reference
Network Configuration Settings (CC-Link IE TSN Configuration)	Perform the parameter settings of device stations, the detection of connected/disconnected devices, or others.	Page 153 "CC-Link IE TSN Configuration" Window (Network Configuration Settings)
Refresh Setting	Assign link refresh ranges between the devices described below. • SB, SW, link devices of the CC-Link IE TSN function part ↔ Devices of the CPU function part • SB, SW of the CC-Link IE TSN function part ↔ Module label	Page 1236 Link Refresh
Network Topology	Select the network topology type according to the actual network configuration.	Page 147 Network Topology
Communication Period Setting	Set the basic cycle setting and multiple cycle setting.	Page 287 Basic period setting Page 293 Multiple period setting
Connection Device Information	Set the information of the connected device.	Page 148 Connection Device Information
Device Station Setting	Set the number of consecutive communication failures until a device station is considered disconnected.	Page 150 Device Station Setting

Network Topology

Select the network topology type according to the actual network configuration.

"Module Parameter (CC-Link IE TSN)" ⇨ "Basic Settings" ⇨ "Network Topology"

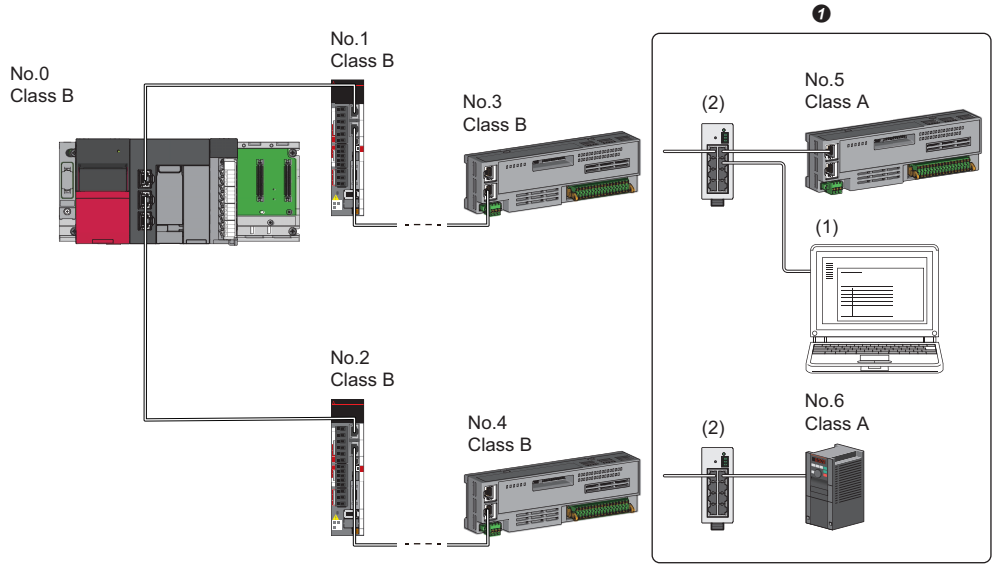


Item	Description	Setting range
Network Topology	Select the network topology type according to the actual network configuration. If a parameter where the ring topology is set is written to the controller, an error (error code 3A32H) occurs.	(Default: Line/Star)

Connection Device Information

Set the information of the connected device.

"Module Parameter (CC-Link IE TSN)" ⇨ "Basic Settings" ⇨ "Connection Device Information"



Item	Description	Setting range
CC-Link IE TSN Class Setting	Set the CC-Link IE TSN Class of the connected device.	• CC-Link IE TSN Class B Only • Mixture of CC-Link IE TSN Class B/A or CC-Link IE TSN Class A Only (Default: CC-Link IE TSN Class B Only)
CC-Link IE TSN Class A Group Send Upper Limit Size Setting	Set the upper limit size of CC-Link IE TSN Class A group send. (☞ Page 312 CC-Link IE TSN Class A group send) The setting is available when "CC-Link IE TSN Class Setting" is set to "Mixture of CC-Link IE TSN Class B/A or CC-Link IE TSN Class A Only".	• 2K bytes • 8K bytes (Default: 2K bytes)
TSN HUB Setting	Set whether to use an industrial switch (CC-Link IE TSN Class B certified). The setting is available when "CC-Link IE TSN Class Setting" is set to "Mixture of CC-Link IE TSN Class B/A or CC-Link IE TSN Class A Only" and "CC-Link IE TSN Class A Group Send Upper Limit Size Setting" is set to "8K bytes".	• Not to Use TSN HUB • Use TSN HUB (Default: Not to Use TSN HUB)

■CC-Link IE TSN Class setting

From "Connection Device Information" under "Basic Settings" of the engineering tool, select either of the following items according to devices to be connected.

Connection device information	System configuration	Supported standard
CC-Link IE TSN Class B Only	Select this if the system is to be configured without connecting the CC-Link IE TSN Class A device. • ☞ Page 173 Connection with modules on CC-Link IE TSN only • ☞ Page 176 Connection with modules on CC-Link IE TSN and Ethernet devices	IEEE 802.1AS
Mixture of CC-Link IE TSN Class B/A or CC-Link IE TSN Class A Only	Select this information if connecting a CC-Link IE TSN Class A device or Ethernet device to a configuration consisting only of CC-Link IE TSN Class B devices. (☞ Page 187 Connection with modules on CC-Link IE TSN and Ethernet devices)	IEEE 802.1AS or IEEE 1588

When "Mixture of CC-Link IE TSN Class B/A or CC-Link IE TSN Class A Only" is set in the "Connection Device Information" setting, connection is possible even in the configuration consisting of CC-Link IE TSN Class B devices only as shown below. Select this setting when connecting (2) Ethernet switch to the end of a CC-Link IE TSN Class B device-only configuration to connect CC-Link IE TSN Class A devices or Ethernet devices.

No.0: Master station
No.1 to 6: Remote stations
(1) Ethernet device
❶ When connecting CC-Link IE TSN Class A devices or Ethernet devices

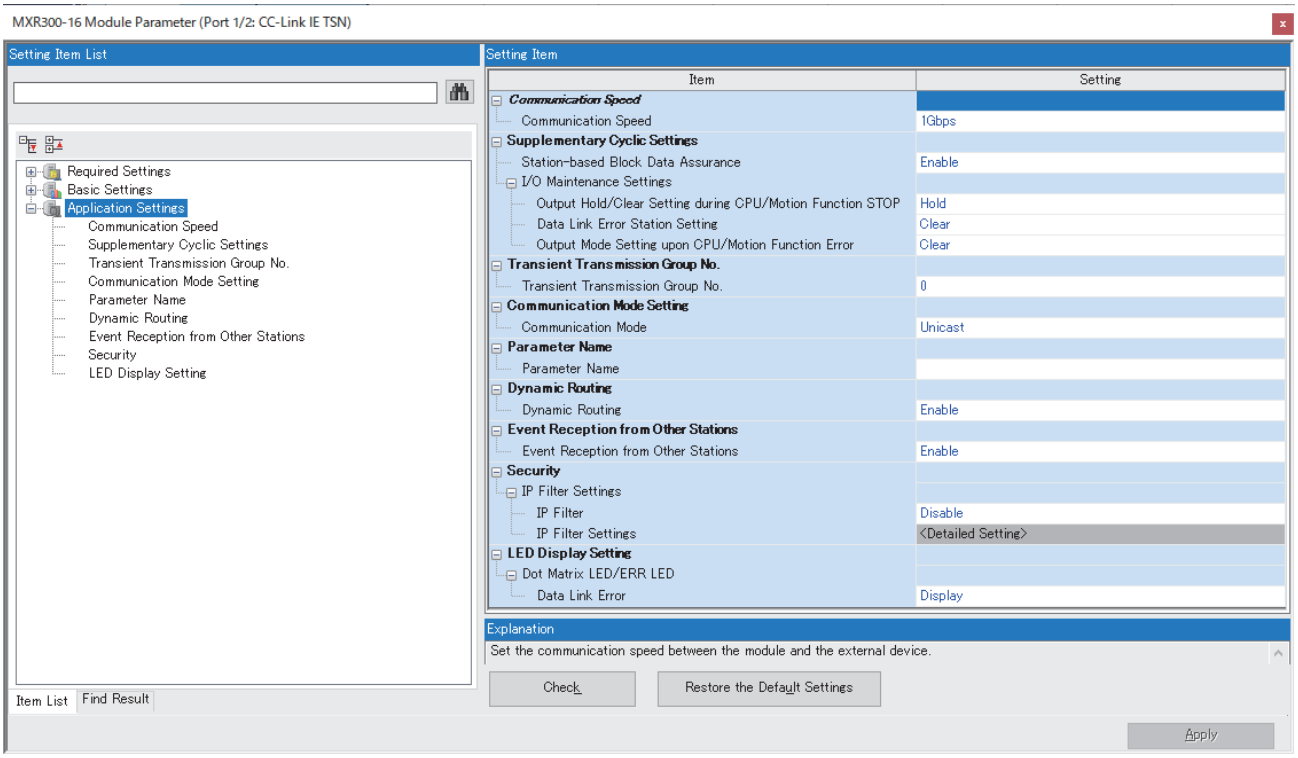
■Precautions

When "CC-Link IE TSN Class A Group Send Upper Limit Size Setting" is set to "8K bytes" in a configuration with mixed CC-Link IE TSN Class B devices and CC-Link IE TSN Class A devices, set "TSN HUB Setting" to "Use TSN HUB" when connecting the TSN HUB.

Device Station Setting

Set items related to the device station.

"Module Parameter (CC-Link IE TSN)" ⇨ "Basic Settings" ⇨ "Device Station Setting"



Item	Description	Setting range
Disconnection Detection Setting	Set the number of consecutive communication failures until a device station is considered disconnected.	• 2 times • 4 times • 8 times (Default: 4 times)

9.3 Application Settings

Set the parameters such as the communication speed setting of the controller.

Navigation window ⇨ [Parameter] ⇨ Controller model ⇨ [Module Parameter (Port 1/2: CC-Link IE TSN)] ⇨ [Module Parameter (CC-Link IE TSN)] ⇨ [Application Settings]

Item	Description	Reference
Communication Speed	Set the communication speed with the external device.	Page 152 Communication Speed
Supplementary Cyclic Settings	Set the station-based block data assurance and I/O maintenance settings.	Page 1246 Station-based block data assurance Page 1247 I/O Maintenance Settings
Transient Transmission Group No.	Set the transient transmission group number. Do not change the number. If a parameter where any of the setting values 1 to 32 is set for "Transient Transmission Group No." is written to the controller, an error (error code 3A6EH) occurs.	—
Communication Mode	Set the communication mode.	Page 152 Communication Mode Setting
Parameter Name	Set a name for the module parameter if desired.	Page 152 Parameter Name
Dynamic Routing	Select whether to enable the dynamic routing function.	Page 1255 Dynamic routing setting
Event Reception from Other Stations	Select whether to obtain the events occurring in the other stations.	Page 1757 Event Reception from Other Stations
Security	Set the security measures for access to the Ethernet device.	Page 1582 IP Filter Function
LED Display Setting	Set the LED display.	Page 1770 LED display setting

Communication Speed

Set the communication speed with the external device.

"Module Parameter (CC-Link IE TSN)" ⇨ "Application Settings" ⇨ "Communication Speed"

Item	Description	Setting range
Communication Speed	Set the communication speed with the external device.	• 1Gbps • 100 Mbps (Default: 1Gbps)

For details on the connection of modules or devices based on the communication speed setting, refer to the following.

☞ Page 171 Structure with CC-Link IE TSN Class B Devices Only

☞ Page 178 Structure with CC-Link IE TSN Class B/A Devices

Communication Mode Setting

Set the communication mode.

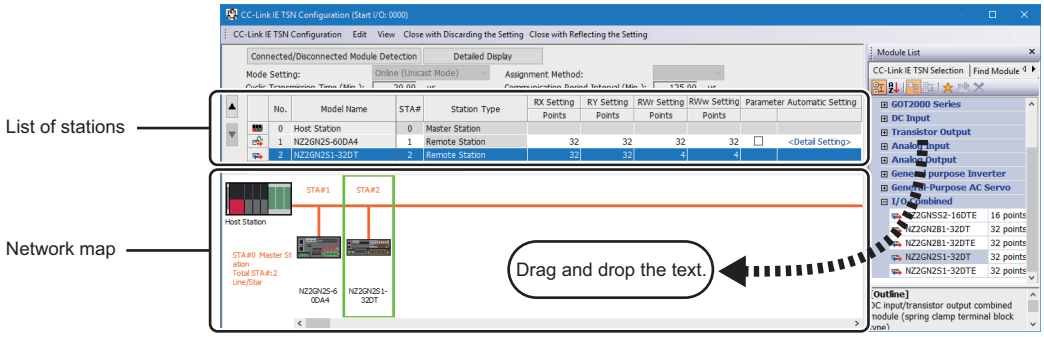
Item	Description	Setting range
Mode	Set the communication mode. If a parameter where the multicast is set is written to the controller, an error (error code 3A6EH) occurs.	Unicast (Default: Unicast)

Parameter Name

Set a name for the module parameter if desired.

Item	Description	Setting range
Parameter Name	Set a name for the module parameter if desired.	Up to 8 one-byte or two-byte characters (Default: Empty)

9.4 "CC-Link IE TSN Configuration" Window (Network Configuration Settings)



Perform the parameter setting of device stations, the detection of connected/disconnected devices, or others.

Navigation window ⇨ "Parameter" ⇨ "Controller model name" ⇨ Module Parameter (Port 1/2: CC-Link IE TSN) ⇨ Module Parameter (CC-Link IE TSN) ⇨ "Basic Settings" ⇨ "Network Configuration Settings"

Parameter setting of a device station

Set parameters of device stations (such as the number of points and assignment of link devices) in the master station.

1. Select the module in "Module List" and drag it to the list of stations or the network map.

2. Set the required items.
3. Check the system configuration.

[CC-Link IE TSN Configuration] ⇨ [Check] ⇨ [System Configuration]

An error or a warning message appears on the output window, refer to the following.

MELSOFT Navigator MessageNo.

4. Select [Close with Reflecting the Setting] and close the "CC-Link IE TSN Configuration" window.

Setting items

- Simple Display: Click the [Simple Display] button to display a narrow portion of items. Use for operation with default settings or the minimum required settings. (Default)
- Detailed Display: Click the [Detailed Display] button to display all items.

Item (Detailed display)		Description	Setting range
Mode Setting		The settings for "Module Operation Mode" and "Communication Mode" is displayed. For details on the settings, refer to the following. • Module Operation Mode: ☞ Page 1769 Module communication test • Communication Mode: ☞ Page 152 Communication Mode Setting	—
Assignment Method		Select a link device assignment method. • Points/Start: Enter the number of link devices and the start number. • Start/End: Enter the start and end numbers of link devices.	• Points/Start • Start/End (Default: Start/End)
No.		The total number of device stations set in the "CC-Link IE TSN Configuration" window is displayed.	—
Model Name		The module model name is displayed. To set a module where the profile is not registered, select it from the "General CC-Link IE TSN Module" list or register the profile before setting the model name. For how to register a profile, refer to the following. 📖GX Works3 Operating Manual	—
STA#		Enter the station number of each device station connected to the network. Station numbers do not need to be set consecutively, but must be unique.	• Master Station: Fixed to "0" • Device station: 1 to 253 (Default: Serial number of added stations)
Station Type		Set the station types. Select the station types same as those of the modules connected to the network. If a parameter where the connection to a local station is set is written to the controller, an error (error code 3A6EH) occurs.	• Remote Station (Default: Varies depending on the set module)
Network Label		Set this item to enable the network label generation. ☞ Page 108 Network labels	—
Number of input/output bit points[*1]	RX Setting	Assign RX/RY points in increments of 16. (☞ Page 1235 Communications Using RX, RY, RWr, and RWw) For modules for which the settings are provided by the device profile, this item is automatically set through selected models. (Excluding modules with a number of points that is not fixed)	• Points: None, 16 to 16384 • Start: 0000H to 3FF0H • End: 000FH to 3FFFH (Default: Varies depending on the set module)
	RY Setting		
Number of input/output word points[*1]	RWr Setting	Assign RWr/RWw points in increments of 4. (☞ Page 1235 Communications Using RX, RY, RWr, and RWw) For modules for which the settings are provided by the device profile, this item is automatically set through selected models. (Excluding modules with a number of points that is not fixed)	• Points: None, 4 to 8192 • Start: 0000H to 1FFCH • End: 0003H to 1FFFH (Default: Varies depending on the set module)
	RWw Setting		
—	LB Setting	If a parameter where "LB Setting" and "LW Setting" are set is written to the controller, an error (error code 3A6EH) occurs.	—
	LW Setting		—
Parameter Automatic Setting		Set whether to set the parameters of each device station automatically. This cannot be set for extension modules. However, the parameter automatic setting of extension modules is interlocked with the settings of the connected main module. ☞ Page 157 Device station parameter automatic setting	• Checked: Distribute parameters • Not checked: Do not distribute parameters. (Default: Not checked)
PDO Mapping Setting		Set the PDO mapping to the station that supports CANopen communications. (☞ Page 165 PDO mapping setting)	—
IP Address		Set the IP address of a station that performs cyclic transmission.	0.0.0.1 to 223.255.255.254 (Default: The first to third octets have the same values as the master station, the fourth octet has a serial number from 1 to 254.)
Subnet Mask		Set a subnet mask to identify a network address. Set the same value for the master station and device station. Even if a device station has a different subnet mask from the master station, it does not result in an input error. If 255.255.255.255 is set, leave it empty.	• 0.0.0.1 to 255.255.255.255 (00.00.00.01 to FF.FF.FF.FF) • Empty (Default: Empty[*2])
Default Gateway		Set the default gateway address to connect to the external network.	• 0.0.0.1 to 223.255.255.254 (00.00.00.01 to DF.FF.FF.FE) • Empty (Default: Empty)

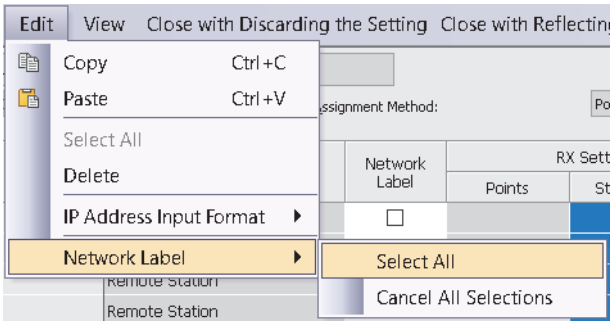
Item (Detailed display)	Description	Setting range
Reserved/Error Invalid Station	Set the device station as a reserved station or error invalid station. • No Setting: The device station is connected to the network. • Reserved Station: The device station is reserved in the parameters for future expansion. By using a reserved station, link device assignment will not change even if the device station is added (reservation is canceled). Therefore, modification of the program is not required. Physical connection of the device station is not required. • Error Invalid Station: Even if a device station is disconnected during a data link, the master station will not detect the device station as a faulty station.	• No Setting • Reserved Station • Error Invalid Station (Default: No setting, master station is fixed as empty)
Network Synchronous Communication	Set whether to synchronize each device station with network synchronous communication. (☞ Page 286 Network Synchronous Communication) When "PDO Mapping Setting" is provided for the set device station, the default is "Synchronous". If a module controlled by the motion system is set to "Asynchronous", an error code (3407H) occurs. For modules controlled by the motion system, refer to the following. ☞ Page 530 Specifications of Modules on CC-Link IE TSN Configuration Controlled by the Motion System	• Synchronous • Asynchronous (Default: Varies depending on the set module)
Communication Period Setting	When multiple communication cycles are set, set the cycle of each device station. (☞ Page 292 Communication cycle coexistence)	• Basic Period Setting (default) • Normal-Speed • Low-Speed
Station Information	■Alias Enter the name of a device if required. The name entered is displayed in "Network Status" of the "CC-Link IE TSN/CC-Link IE Field Diagnostics" window. For the extension module of the remote station, the name is not displayed in the "CC-Link IE TSN/CC-Link IE Field Diagnostics" window, even if entered.	Up to 32 one-byte characters (one-byte or two-byte) (Default: Empty)
	■Comment Information entered in "Comment1" on the "Properties" window displayed by right-clicking the module in the list of stations or the network map is displayed.	Up to 32 one-byte characters (one-byte or two-byte) (Default: Empty)
	■Station-specific mode setting Set the station-specific mode of the device station. (Only when the device station supports the station-specific mode.)	The setting varies depending on the set device station.
CC-Link IE TSN Class Setting	Select the CC-Link IE TSN Class of the device for each device station.	• CC-Link IE TSN Class B • CC-Link IE TSN Class A (Default: Automatically judged based on the profile)
Cyclic Transmission Distribution Setting	Set whether or not to perform cyclic transmission distribution. For details on cyclic transmission distribution, refer to the following. ☞ Page 310 Cyclic transmission distribution	• Do not distribute • Distribute (Default: Do not distribute)

*1 If the number of link device points assigned to a station whose CC-Link IE TSN Class is CC-Link IE TSN Class A exceeds the number of points that can be assigned, a link device number of points error (error code: 3AD8H) occurs. For the number of points that can be assigned to CC-Link IE TSN Class A device stations, refer to the following.
☞ Page 156 Number of link devices that can be assigned to a CC-Link IE TSN Class A device station

*2 If "Subnet Mask" is set in "Station No./IP Address Setting" of "Required Settings", the same value is set as default.

Point

- Because a portion of the setting items are not displayed in simple display, when there are deficiencies in setting items that are not displayed, the "Output" window may display a warning or error by selecting [Close with Reflecting the Setting].
  If a warning is displayed, switch to detailed display and correct the items.
- Up to 253 stations with station numbers can be set, and up to 256 stations can be set for network configuration. When using extension modules that support CANopen communication, each module is counted as one station.



■Network labels

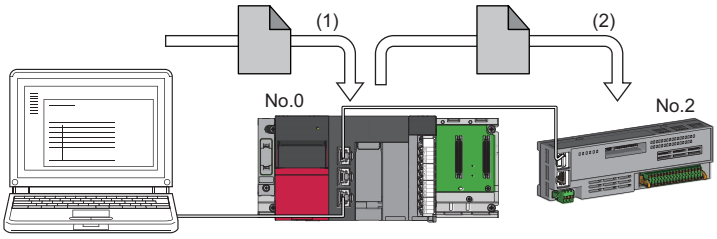
Device stations with "Network Label" selected are target stations for network label generation. (☞ Page 108 Network labels)

	No.	Model Name	Station Type	Network Label
	0	Host Station	Master Station	☐
	1	MR-J5-G	Remote Station	☑
	2	NZ2GN2S1-16D	Remote Station	☑
	3	NZ2GN2S1-16D	Remote Station	☑

Point

When [Edit] ⇨ [Network Label] ⇨ [Select All] is selected, all remote stations can be targeted.

■Number of link devices that can be assigned to a CC-Link IE TSN Class A device station



The number of points of link devices assigned to a CC-Link IE TSN Class A device station must satisfy the following two conditional formulas.

- (Number of points of "RY Setting" ÷ 8) + (Number of points of "RWw Setting" × 2) ≤ 1912
- (Number of points of "RX Setting" ÷ 8) + (Number of points of "RWr Setting" × 2) ≤ 1872

Device station parameter automatic setting

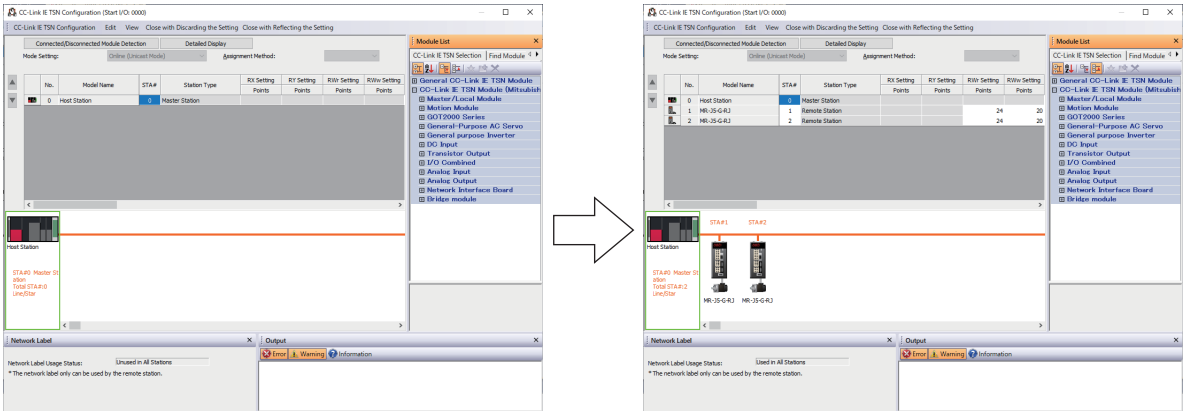
This function uses parameters of the device station saved to the master station to set the parameters automatically when the device station is connected or returned to the network.

1. Save parameters of the device station set using the engineering tool to the controller memory or the SD memory card by writing them.
2. When the device station is connected/returned by an operation such as power-on, saved parameters are automatically set from the master station.

(1) Save the parameters of the device station to the controller of the master station.
(2) When the device station is connected/returned, saved parameters are automatically set from the master station to the device station.

Point

- The master station starts data link with the device station after parameters of the device station are automatically set.
- The device station parameter automatic setting is also executed for device stations set as reserved stations.



Precautions

- A device station where the device station parameter automatic setting abnormally ended does not start data link, and 'Execution result of device station parameter automatic setting function (station numbers 1 to 253)' (SW0200 to SW020F) turns on. Check 'Detailed execution result of device station parameter automatic setting' (SW0194) and the event history and perform corrective actions according to Action of the error codes list.
- Use 'Execution result of device station parameter automatic setting function (station numbers 1 to 120)' (SW0160 to SW0167) when the station number of the device station to be connected is 120 or less and an existing program is used.
- Check if the checkbox of "Parameter Auto-setting" of the device station is selected in the "CC-Link IE TSN Configuration" window.
- Check if the IP address of the device station in the "CC-Link IE TSN Configuration" window matches the actual IP address of the device station.
- When communication speeds are different between the master station and the station where the device station parameter automatic setting is performed, the device station parameter automatic setting may end abnormally. If the setting ends abnormally, check if the communication speeds are matched.
- When saving the parameters of a device station in the SD memory card, set "Use" for "Device Station Parameter" in "Setting of File/Data Use or Not in Memory Card" in "Memory Card Parameter" of the controller.
- In the "CC-Link IE TSN Configuration" window of all master stations controlled by the controller, ensure that the total number of files for the device station parameter automatic setting targets including extension modules is 2048 or less.
- If the device station parameter automatic setting is completed with an error, connect/return the device station and perform the device station parameter automatic setting again. Or write the device station parameters.

Detection of connected/disconnected devices

Connected device stations are detected and displayed on the "CC-Link IE TSN Configuration" window.

1. Click the [Connected/Disconnected Module Detection] button.
2. When the [Execute] button is clicked according to the instruction on the window, connected device stations are detected and displayed on the "CC-Link IE TSN Configuration" window.

3. Check items in the list of stations and change them as necessary. (☞ Page 154 Setting items)
4. Select [Close with Reflecting the Setting] and close the "CC-Link IE TSN Configuration" window.

Point

Detection of connected/disconnected devices cannot be executed in the following cases.

- The controller is not in the online mode. (☞ Page 1769 Module communication test)
- The actual system configuration is incorrect. (An overlapping IP address or others)
- In "Setting to Use or Not to Use Default Open Port", "CC-Link IE TSN Connection" is set to "Close". (☞ Page 1585 Default Open Port Usage Setting Function)

Connection/Disconnection/Replacement

When the [Connected/Disconnected Module Detection] button is clicked while the saved CC-Link IE TSN configuration is displayed, IP addresses of detected device stations are compared with the saved IP addresses of device stations and displayed as follows by connection/disconnection/replacement.

IP address verification result	Operation	Display	When station numbers of detected device stations are not set
Detected device stations are not in the saved CC-Link IE TSN structure.	Connect	Detected device stations are added. (Settings other than "IP Address", "STA#", and "Station Type" are default) When adding a device, the settings other than IP address, station number, and station type are set to the defaults. (However, if the station number of the detected device has not been set, the station number is also set to the default.*1) Added device stations are displayed in the list of stations in the following order. • Modules other than extension modules: In the order of IP addresses, following disconnected device stations. • Extension modules: In the order of sub-IDs, following connected main modules and extension modules.	A station number is automatically numbered as the youngest unused station number in the range from 1 to 253. The order of automatic numbering is the same as the displayed order in the list of stations (see left).
Device stations in the saved CC-Link IE TSN structure are not detected.	Disconnect	• Modules other than extension modules: Setting of "Reserved/Error Invalid Station" is changed to "Reserved Station". • Extension modules: Are deleted.	—
Detected device stations are in the saved CC-Link IE TSN structure.	Replace	When parameters between a detected device station and a saved CC-Link IE TSN structure mismatch, the parameters are replaced with the parameters of the detected device station. When the model name, model version, and station type are mismatched, the following settings are inherited. • "RX Setting", "RY Setting", "RWr Setting", "RWw Setting", "LB Setting", "LW Setting" • "IP Address" of the master station • "Subnet Mask" • "Default Gateway" • "Reserved/Error Invalid Station" (Note that if "Reserved Station" is set, the setting will change to the default.) • "Network Synchronous Communication" • "Communication Period Setting" If only the station number is mismatched, only the station number is reflected, and all the settings are inherited. (Note that if the station number of the detected device has not been set, the station number of the device before replacement is inherited.)	The station number takes over the station number of the saved CC-Link IE TSN structure.

*1 A station number is automatically numbered as the youngest unused station number in the range from 1 to 253. If the numbers do not match between the automatically numbered station and the station numbered by the detected device station, take either of the following actions.

· Change the station number in "Network Configuration Settings" of the master station to the same value as the station number set by the device station.

· Change the station number of the device station to the same value as the station number set in "Network Configuration Settings" of the master station.

Precautions

- When the station number is set in the device station using the CC-Link IE TSN structure and parameters are written in the controller, the station number of the device station is held in the master station. When parameters are not to be written in the controller, they are saved in the CC-Link IE TSN structure as device stations with the station number not set.
- In "Setting to Use or Not to Use Default Open Port", when "CC-Link IE TSN Connection" is set to "Close", even if this function is executed, device stations cannot be detected and the network configuration settings are not automatically configured.
- If the actual system configuration is incorrect, executing this function may not automatically set some or all device stations. Check that nothing is incorrect in the system configuration before executing.

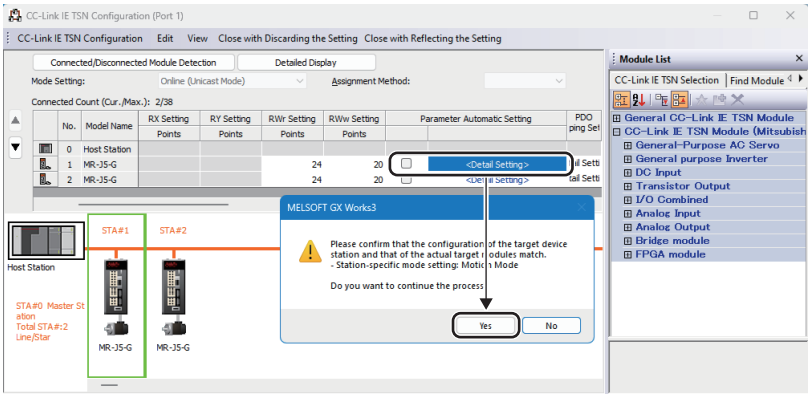
Point

Register the profile of the target device to detect in advance.
If the profile is not registered, the following may be displayed.
- "Model Name" is "General Remote Station" or "General Extension Module".
- "Station Type" is "Remote Station" or "Extension Module".

For how to register a profile, refer to the following.
GX Works3 Operating Manual

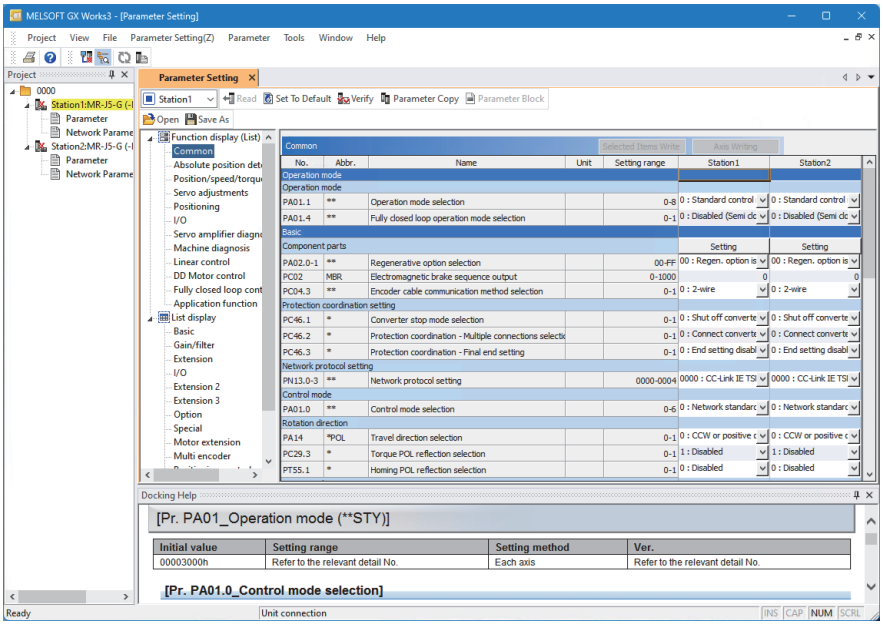
Restriction

Even when the profile is registered, if modules that are not available for detection of connected/disconnected devices are used, "Model Name" and "Station Type" are not displayed correctly.



Parameter processing of a device station

The processing is to read and save the parameters from the device station, and to write the saved parameters to the device station.

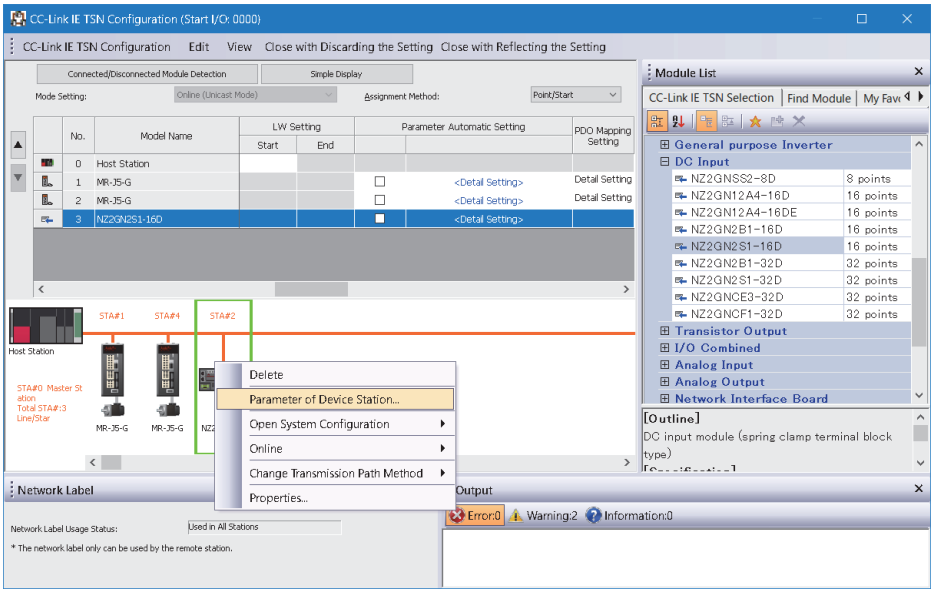


Also, it automatically sets parameters of the device station from the master station. (☞ Page 157 Setting items)

For the MR-J5(W)-G

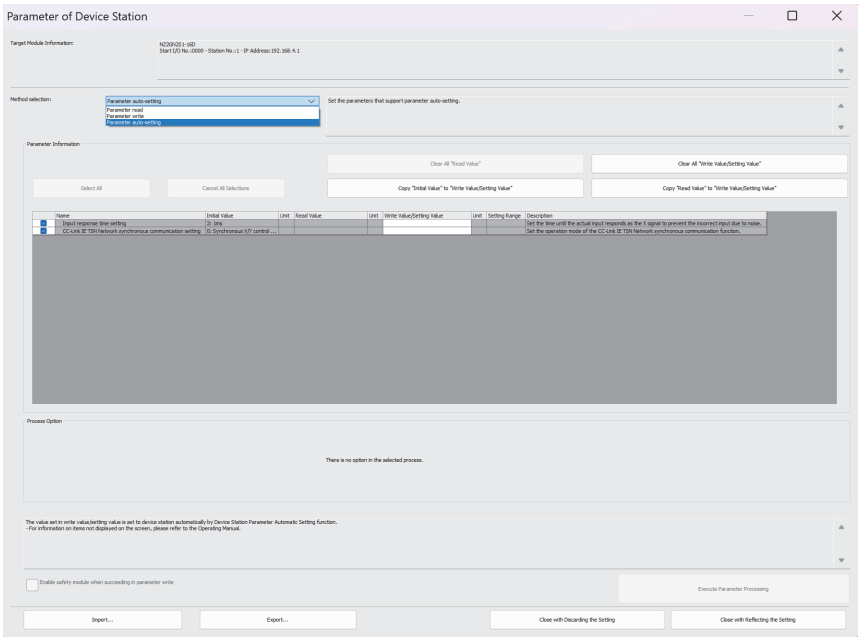
[Module Parameter (Port 1/2: CC-Link IE TSN)] ⇨ [Module Parameter (CC-Link IE TSN)] ⇨ [Basic Settings] ⇨ [Network Configuration Settings]

Select "Parameter Automatic Setting" ⇨ <Detailed Setting> to display the "Parameter Setting" window.



In addition to setting device station parameters, the following can be performed. For details on the window, refer to [Help].

- Reading and writing parameters for the MR-J5(W)-G during data link (during online)
- Saving the MR-J5(W)-G parameters to a separate file/Reading them from the file where they have been saved



When the settings are completed, close the "Parameter Setting" window by selecting [Project] ⇨ [Exit MR Configurator2] or clicking the [Close] button in the upper right corner of the window.

For modules other than the MR-J5(W)-G

Navigation window ⇨ "Parameter" ⇨ "Module Information" ⇨ Target module ⇨ "Basic Settings" ⇨ "Network Configuration Settings"

Select and right-click the device station, and select "Parameter of Device Station" to display the "Parameter of Device Station" window.

Item		Description
Target Module Information		Information for the selected device stations is displayed.
Method selection		Select processing to be executed for selected device stations. • Parameter auto-setting: Automatically set contents of "Write Value/Setting Value" to the device station. (☞ Page 157 Setting items) • Parameter read: Read parameters from the selected device station. • Parameter write: Write parameters to the selected device station.
Parameter Information	[Clear All "Read Value"] button	Click to clear all setting details that were read using "Parameter read".
	[Clear All "Write Value/Setting Value"] button	Click to clear all setting details that are written using "Parameter write".
Processing Option		When there are options for processing selected by "Method selection", setting items are displayed.
[Import] button		Read contents of parameter processing created in a CSV file.
[Export] button		Output contents of parameter processing set in this window to a CSV file.

Clearing a saved parameter

■Procedure

When returning the saved parameters of a not-required device station to the not-set status, perform the following procedure.

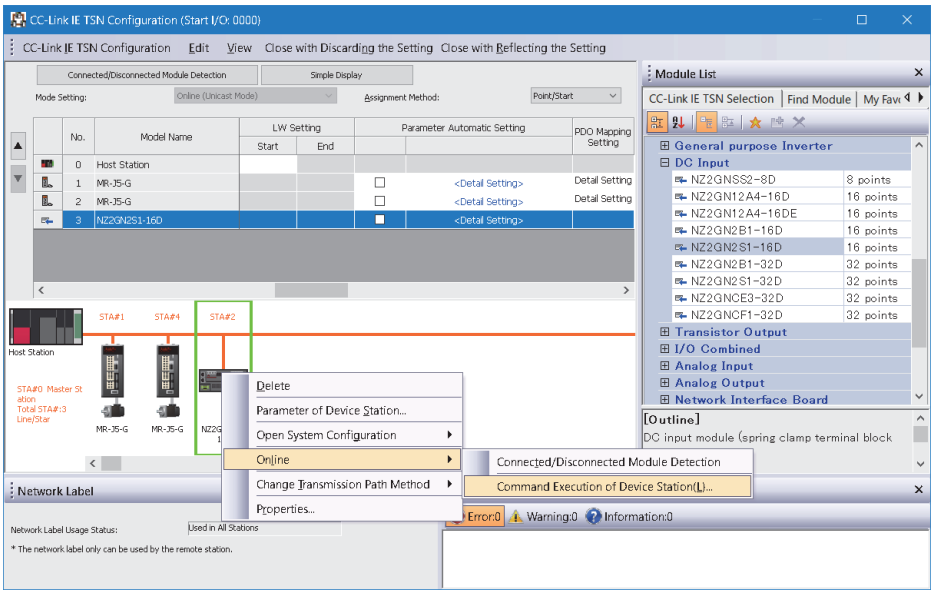
1. If the saved parameters are to be saved, output them in a CSV file using the [Export] button.
2. Delete not-required device stations from the list of stations.
3. Select the same module as the deleted device station in "Module List", and drag it to the list of stations or the network map.

■Conditions

Saved parameters of a device station can be cleared under the following conditions.

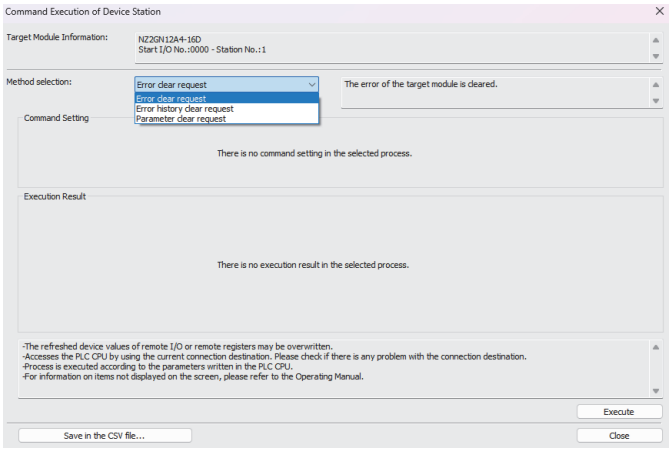
When saved parameters are cleared, execute "Parameter auto-setting" or "Parameter read" in the "Parameter of Device Station" window and read the parameters of the device station.

Item	Operation	Description
"CC-Link IE TSN Configuration" window	Open the "CC-Link IE TSN Configuration" window.	When there is no device station with a station number that matches the saved parameter information in the "CC-Link IE TSN Configuration" window, the saved parameters of the relevant device station are skipped. Skipped parameters of the device station are deleted.
	Reflect the setting and close the window.	Saved parameters of a device station that is not in the actual system configuration are cleared.
	Execute detection of connected/disconnected devices.	All saved parameters are cleared.
	Change the function version in the "Properties" window.	When the "Properties" window is closed, saved parameters are cleared.
"Parameter of Device Station" window	Open the "Parameter of Device Station" window.	Saved parameters that mismatch the relevant device station are skipped. Clicking the [Close with Reflecting the Setting] button in the above state clears the skipped saved device station parameters.
Module Parameter	Manually delete "Network Configuration Settings" to apply.	Parameters of "Network Configuration Settings" return to default.
	Change "Station Type" or set parameters that do not exist.	
System Parameter	Divert system parameters from another project.	Parameters of the device station are not diverted.
Module Configuration	Delete a module and check.	Parameters are deleted together with the module.
Navigation window	Delete a module.	
Read from PLC	Read module parameters that have a different network configuration and the same start I/O number.	Parameters are overwritten.
Navigation window	Import the data of the controller to take network settings.	
MELSOFT Navigator	Reflect the parameters.	Saved parameters are cleared.



Precautions

If writing parameters to the device station is completed with an error, write the parameters to the device station again.



Command execution to device stations

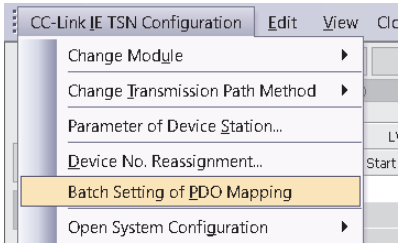
Commands to a device station (Error clear request, Error history clear request) are executed.

Navigation window ⇨ "Parameter" ⇨ "Module Information" ⇨ Target module ⇨ "Basic Settings" ⇨ "Network Configuration Settings"

Select and right-click the device station, and select "Command Execution of Device Station" from "Online" to display the "Command Execution of Device Station" window.

Item	Description
Target Module Information	Information for the selected device stations is displayed.
Method selection	Select the processing to be executed for the selected device stations. • Error clear request • Error history clear request
Command setting	When there are command settings for the processing selected by "Method selection", setting items are displayed.
Execution Result	Execution results of the processing selected in "Method selection" are displayed.
[Save in the CSV file] button	Outputs the contents of this window to a CSV file.

Precautions



If the command execution to the device station is completed with an error, execute the command to the device station again.

PDO mapping setting

Set the PDO mapping to the station that supports CANopen communications.
When an extension module such as the multi-axis servo amplifier having PDO mapping information is connected, the maximum number of connectable modules varies depending on the number of axes.

"Batch Setting of PDO Mapping"

Set the default PDO mapping to the target device stations at once.

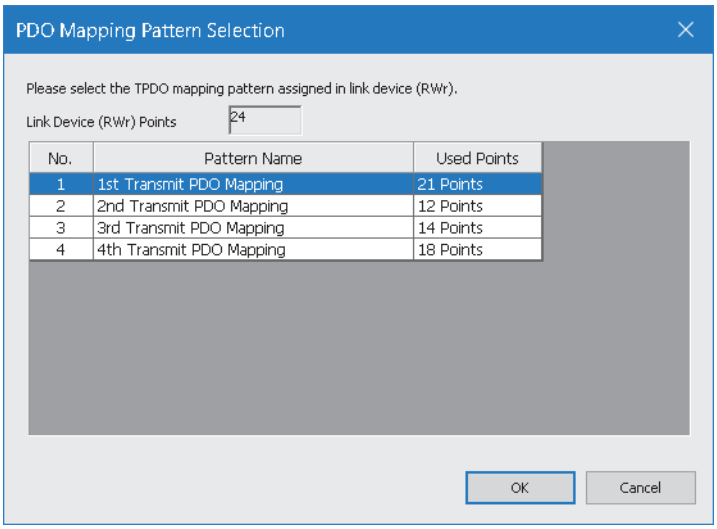
1. Click "Batch Setting of PDO Mapping".

   "Basic Settings" ⇨ "Network Configuration Settings" ⇨ [CC-Link IE TSN Configuration] ⇨ [Batch Setting of PDO Mapping]

2. Check the confirmation message appeared, then click the [OK] button.
3. When the completion window of "Batch Setting of PDO Mapping" appears, click the [OK] button.

Restriction

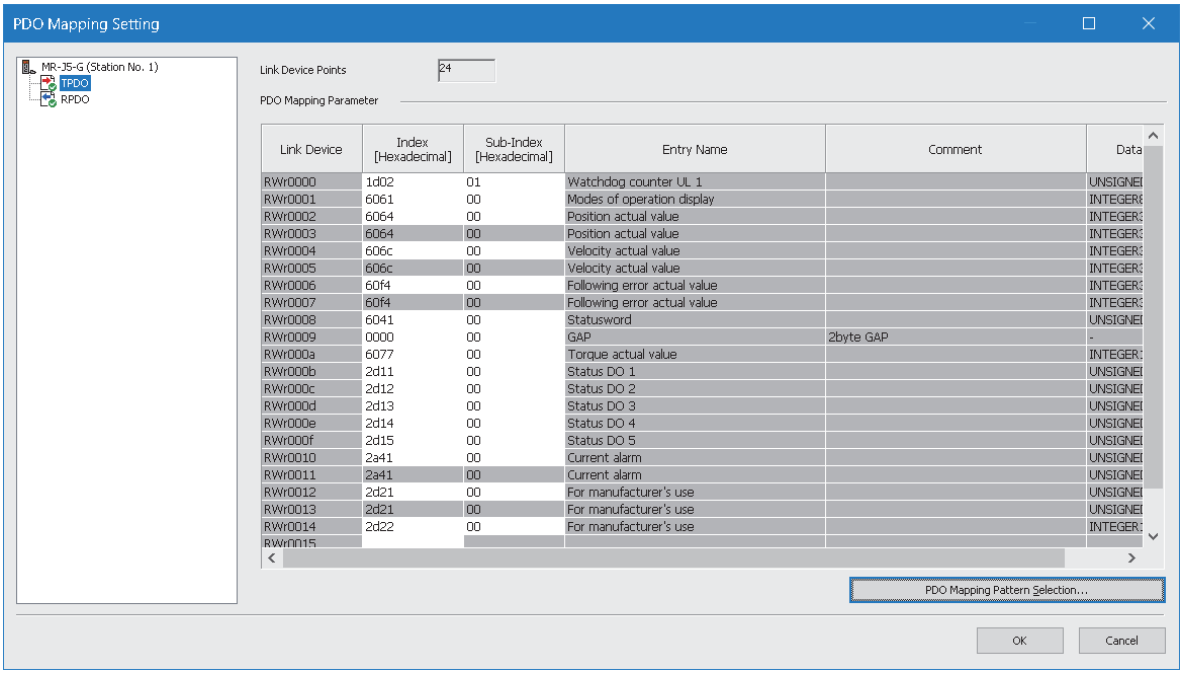
The PDO mapping is not set to the target device stations in the following cases:



- A station that the PDO mapping can be set does not exist.
- The numbers of points of "RWr Setting" and "RWw Setting" are less than the points used in the default pattern.
- The setting is performed when "RWr Setting" and "RWw Setting" are blanks, and the checkbox of "Batch set default pattern only when PDO mapping is unset device station" is not selected.

"PDO Mapping Setting"

Set the PDO mapping of the target device stations individually.



"Basic Settings" ⇨ "Network Configuration Settings" ⇨ "PDO Mapping Setting" ⇨ Double-click <Detailed Setting> of the target device station.

1. Select a PDO mapping pattern of TPDO assigned in the link device (RWr). Click the [OK] button.

2. Select a PDO mapping pattern of RPDO assigned in the link device (RWw). Click the [OK] button.

3. Check the selected PDO mapping pattern.

4. Click the [OK] button to close "PDO Mapping Setting".

Restriction

The PDO mapping is not set to the target device stations in the following cases:

- The number of points in "RWr Setting" is one or more points and an entry is not assigned in TPDO.
- The number of points in "RWw Setting" is one or more points and an entry is not assigned in RPDO.
- A line where "Sub-Index" is blank though a value has been entered in "Index" exists.
- Entries are assigned out of the link device range.
- The same entry is assigned to the multiple link devices.

Precautions

- Ensure that the number of set entries does not exceed 64.
- The number of link devices to which one entry is assigned varies depending on the data length (data type) of the entry. Data length of one entry ÷ 16 bits = Number of link devices (The operation result is rounded up to the nearest integer). For the GAP for 2-byte alignment, assign one entry to one link device.
- When using the watchdog counter, set an object of the watchdog counter for both TPDO and RPDO. If the watchdog counter is not used, delete any objects of the watchdog counter from both TPDO and RPDO. (☞ Page 289 Watchdog counter)
- When writing is performed to objects assigned to a link device in the PDO mapping setting using SDO communication, the written value is overwritten by PDO communication. To write the value using SDO communication, delete the setting of the corresponding object from the PDO mapping setting.

Ex.

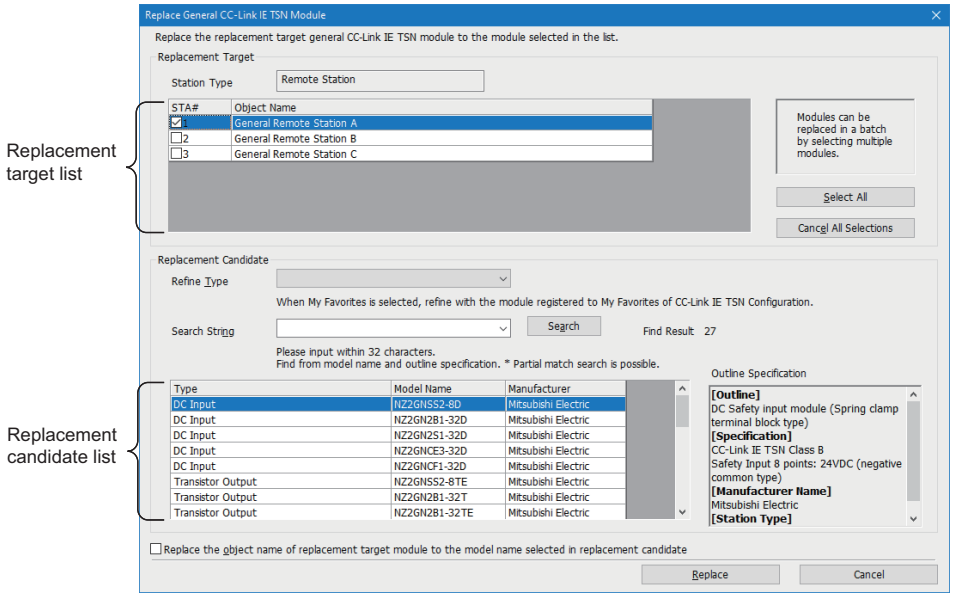
In the following case, 4 entries are assigned to 5 link devices.

PDO Mapping Parameter

Link Device	Index [Hexadecimal]	Sub-Index [Hexadecimal]	Entry Name	Comment	Data Type
RWw001e	1d01	01	Watchdog counter DL 1		UNSIGNED16
RWw001f	6060	00	Modes of operation		INTEGER8
RWw0020	607a	00	Target position		INTEGER32
RWw0021	607a	00	Target position		INTEGER32
RWw0022	0000	00	GAP	2byte GAP	-

Entry 1: 16 ÷ 16 = 1 link device (RWw0030)
Entry 2: 8 ÷ 16 = 0.5 rounded up → 1 link device (RWw0031)
Entry 3: 32 ÷ 16 = 2 link devices (RWw0032, RWw0033)
Entry 4: GAP = 1 link device (RWw0034)

- For a multi-axis servo amplifier, up to eight axes can be set to a single module. If nine or more axes are set, an error occurs, and a parameter error (multidrop number) (error code: D658H) is stored in SW004C (parameter setting status).



Change of module

This section describes how to replace a general CC-Link IE TSN module with a module (device station) and vice versa.

A general CC-Link IE TSN module → A module (device station)

Replace a general CC-Link IE TSN module with a module (device station).

Right-click a general CC-Link IE TSN module from the list of stations on the "CC-Link IE TSN Configuration" window. ⇨ [Change Module] ⇨ Click [Replace General CC-Link IE TSN Module].

Item		Description
Replacement Target	Station Type	Displays the station type of the general CC-Link IE TSN module selected from the list of stations on the "CC-Link IE TSN Configuration" window.
	Replacement target list	Displays general CC-Link IE TSN modules whose station types are the same as the general CC-Link IE TSN modules selected from the list of stations on the "CC-Link IE TSN Configuration" window. By selecting the checkboxes, multiple general CC-Link IE TSN modules can be replaced.
	[Select All] button	Selects all checkboxes in the replacement target list.
	[Cancel All Selections] button	Deselects all checkboxes in the replacement target list.
Replacement Candidate	Refine Type	Narrows the replacement candidates in the list by types.
	Search String	Searches the input string from models and outline specifications.
	[Search] button	Displays the replacement candidate list based on the conditions that was set in "Refine Type" and "Search String".
	Replacement candidate list	The modules to be replaced are displayed.
	Outline Specification	The outline specifications of the module selected in the replacement candidate list are displayed.
	Replace the object name of replacement target module with the model name selected from replacement candidate	By selecting the checkbox, the object name of the replacement target module is replaced with the module model name selected from the replacement candidate.
	[Replace] button	Replaces the module selected in the replacement target list with the module selected in the replacement candidate list.
	[Cancel] button	Cancels the replacement processing and close the window.

A module (device station) → A general CC-Link IE TSN module

Replace a module (device station) with a general CC-Link IE TSN module of the same station type.

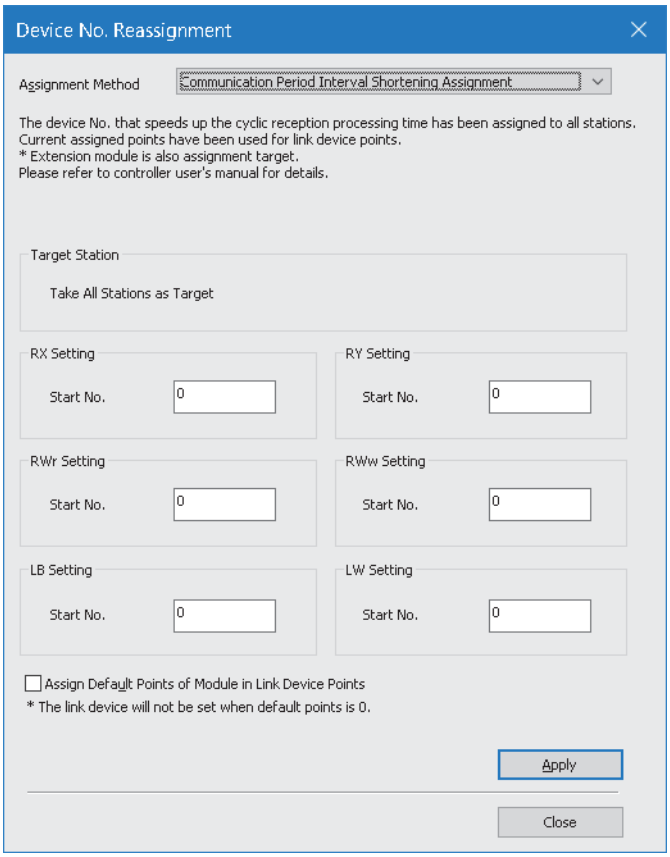
Right-click a device station in the list of stations on the "CC-Link IE TSN Configuration" window. ⇨ [Change Module] ⇨ Click [Change to General CC-Link IE TSN Module].

Device number reassignment

Assign the device numbers successively to the link device of the specified target station.

Point

This setting shortens the communication cycle interval by assigning device numbers by selecting "Communication Period Interval Shortening Assignment" in "Assignment Method". This setting also allows consecutive refresh devices to be more easily set in the refresh settings, creating a good potential of improvement in refresh performance.



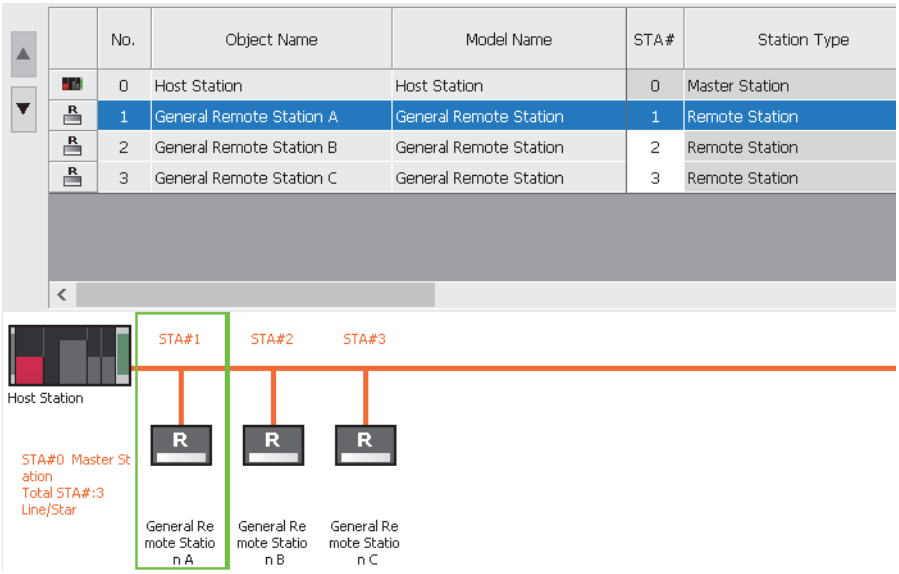
If "Communication Period Interval Shortening Assignment" is selected in "Assignment Method", the device numbers for the RX setting, RY setting, RWr setting, and RWw setting of the device station set in the network configuration settings are assigned consecutively in the following order.

Assignment order	"Network Synchronous Communication"	"Communication Period Setting"
1	"Asynchronous"	"Basic Period"
2	"Asynchronous"	"Normal-Speed"
3	"Asynchronous"	"Low-Speed"
4	"Synchronous"	"Basic Period"
5	"Synchronous"	"Normal-Speed"
6	"Synchronous"	"Low-Speed"

Operating procedure

1. Display "Device No. Reassignment".

[CC-Link IE TSN Configuration] ⇨ [Device No. Reassignment]

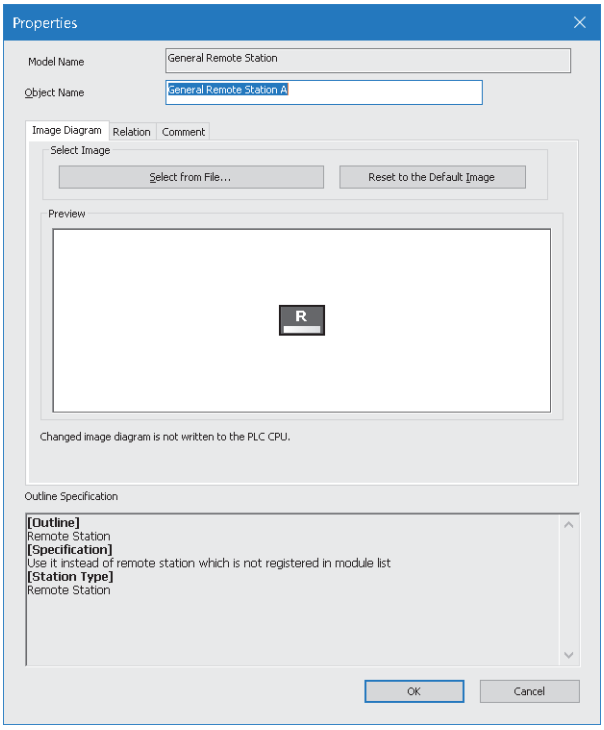


2. Check that "Communication Period Interval Shortening Assignment" is selected in "Assignment Method", and click the [Apply] button.

When the [Apply] button is clicked with the checkbox of "Assign Default Points of Module in Link Device Points" selected, the default points of each module are reassigned. However, if a default number of points is 0, the number of points of corresponding link device is not assigned.

Object name display

The object name of the module displayed in the list of stations on the "CC-Link IE TSN Configuration" window is displayed.

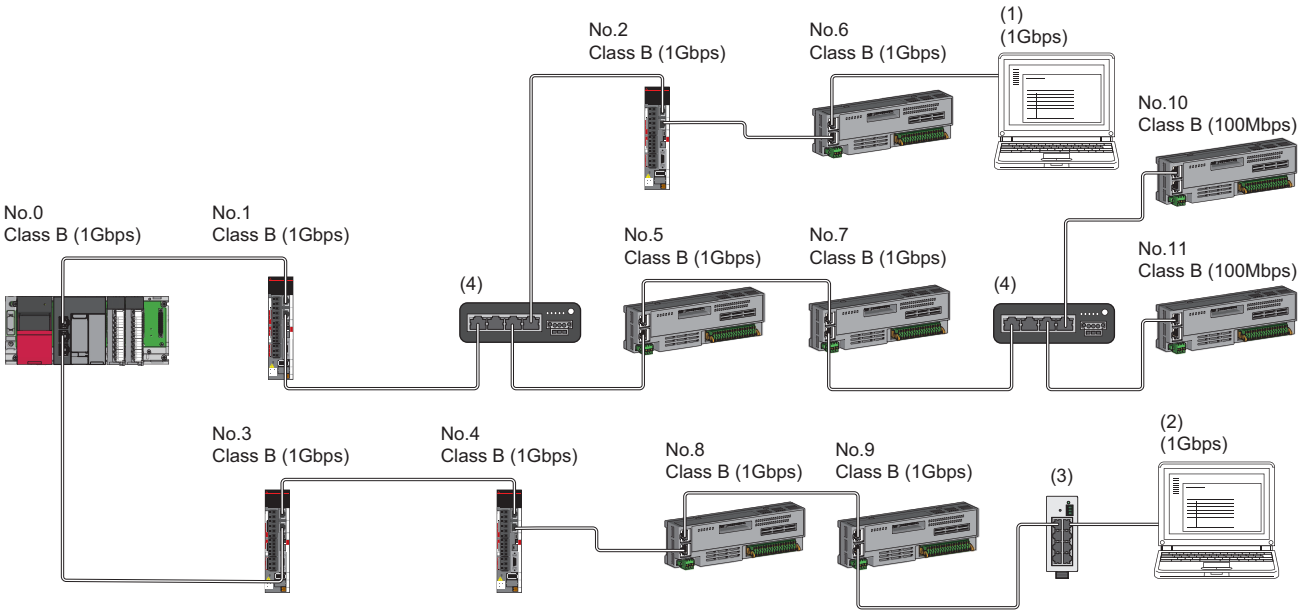


[View] ⇨ [Object Name Display]

Change of object name

Changing object names helps users to identify each module on the "CC-Link IE TSN Configuration" window.

1. In the network map on the "CC-Link IE TSN Configuration" window, right-click the module whose object name is changed and click "Properties".



2. Change "Object Name".

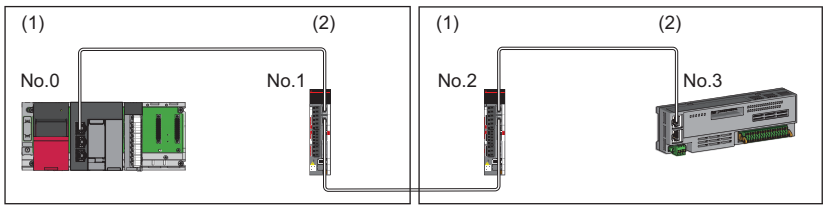
3. Click the [OK] button.

9.5 Structure with CC-Link IE TSN Class B Devices Only

This section describes the system configuration when "Connection Device Information" under "Basic Settings" of the engineering tool is set to "CC-Link IE TSN Class B Only".
When "Connection Device Information" under "Basic Settings" of the master station is set to "CC-Link IE TSN Class B Only", up to 254 stations (one master station and 253 device stations) can be connected.

No.0: Master station
No.1 to 11: Remote stations
(1), (2): Ethernet devices
(3) Ethernet switch
(4) Industrial switch (CC-Link IE TSN Class B certified)
Class B: CC-Link IE TSN Class B device

Point



For the parameter settings related to CC-Link IE TSN system configuration, refer to the following.
☞ Page 153 "CC-Link IE TSN Configuration" Window (Network Configuration Settings)

The availability of connection of network configuration devices varies depending on the communication mode and communication speed.

- Unicast mode

☞ Page 172 When the communication speed for the master station is set to 1Gbps
☞ Page 172 When the communication speed for the master station is set to 100Mbps

The following terms are used to describe the terms in the tables referenced.

No.0: Master station
No.1, No.2, and No.3: Remote stations
(1) Device on the master station side (The master station or a device near the master station)
(2) Device on the end side (A device far from the master station)

Structure of unicast mode

The following table lists the availability of connection with a network configuration device when "Communication Mode" under "Application Settings" is set to "Unicast".

When the communication speed for the master station is set to 1Gbps

The following table lists the availability of connection with a network configuration device when "Communication Speed" for the master station is set to "1Gbps".

○: Connection available, △: Connection available via an Ethernet switch, ×: Connection not available

S: Industrial switches (CC-Link IE TSN Class B certified) can be used.

H: Ethernet switches can be used.

Device on the master station side (A device near the master station)		Device on the end side (A device far from the master station)			
		Remote station (CC-Link IE TSN Class B device)		Ethernet device	
		1Gbps	100Mbps	1Gbps	100Mbps
Master station (CC-Link IE TSN Class B device)	1Gbps	○S	△S*1	○SH	△SH
Remote station (CC-Link IE TSN Class B device)	1Gbps	○S	△S*1*2	○SH	△SH
	100Mbps	×	○S*1*2	×	○SH

*1 For a device station with a communication speed of 100Mbps, set "Communication Period Setting" to "Low-Speed".

*2 A connection cannot be established if the total cyclic data size of all device stations on the 100Mbps device side exceeds 2K bytes. This includes the devices with a communication speed of 100Mbps that form a boundary between the communication speed of 1Gbps and 100Mbps. (☞ Page 189 Calculation of the total cyclic data size)

Precautions

When using an industrial switch (CC-Link IE TSN Class B certified), be sure to check the specifications of the industrial switch (CC-Link IE TSN Class B certified) on the CC-Link Partner Association website at www.cc-link.org.

When the communication speed for the master station is set to 100Mbps

The following table lists the availability of connection with a network configuration device when "Communication Speed" for the master station is set to "100Mbps".

○: Connection available, △: Connection available via an Ethernet switch, ×: Connection not available

S: Industrial switches (CC-Link IE TSN Class B certified) can be used.

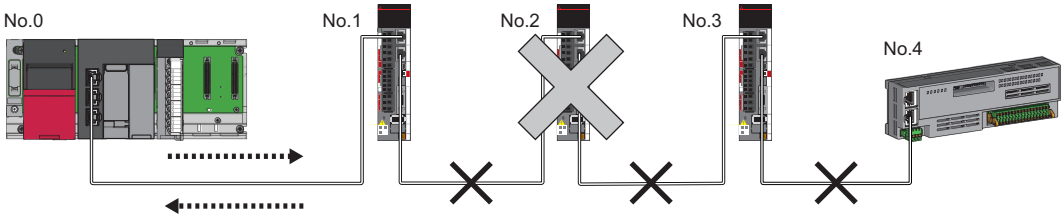
H: Ethernet switches can be used.

Device on the master station side (A device near the master station)		Device on the end side (A device far from the master station)			
		Remote station (CC-Link IE TSN Class B device)		Ethernet device	
		1Gbps	100Mbps	1Gbps	100Mbps
Master station (CC-Link IE TSN Class B device)	100Mbps	×	○S*1	×	○SH
Remote station (CC-Link IE TSN Class B device)	1Gbps	×	×	×	×
	100Mbps	×	○S*1	×	○SH

*1 For a device station with a communication speed of 100Mbps, set "Communication Period Setting" to "Basic Period" or "Normal-Speed".

Precautions

When using an industrial switch (CC-Link IE TSN Class B certified), be sure to check the specifications of the industrial switch (CC-Link IE TSN Class B certified) on the CC-Link Partner Association website at www.cc-link.org.

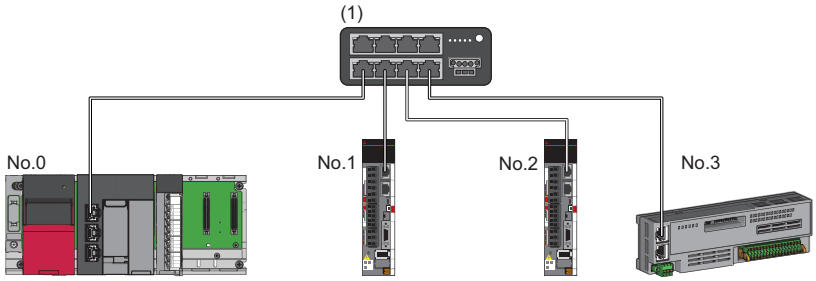


Structure with modules on CC-Link IE TSN only

Connection with modules on CC-Link IE TSN only

■Line topology

The network is configured in a line topology. An industrial switch (CC-Link IE TSN Class B certified) is not required for connection.

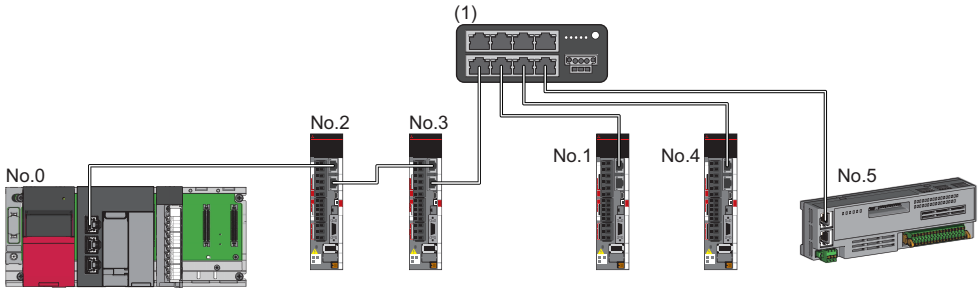


When an error occurs in a device station, the stations connected after the faulty station will be disconnected.

No.0: Master station
No.1 to 4: Remote stations

■Star topology

The modules are connected in a star topology via an industrial switch (CC-Link IE TSN Class B certified). This allows devices to be added easily.



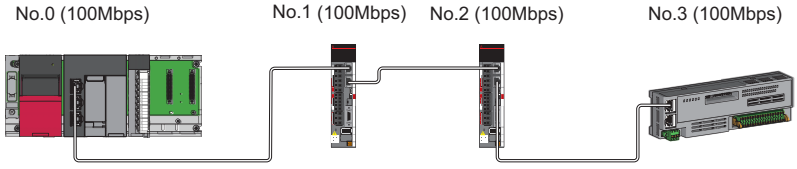
No.0: Master station
No.1, No.2, and No.3: Remote stations
(1) Industrial switch (CC-Link IE TSN Class B certified)

Even when an error occurs in a device station, a data link can be continued with the stations that are operating normally.

■Coexistence of line and star topologies

Line and star topologies are mixed.

No.0: Master station
No.1 to 5: Remote stations
(1) Industrial switch (CC-Link IE TSN Class B certified)



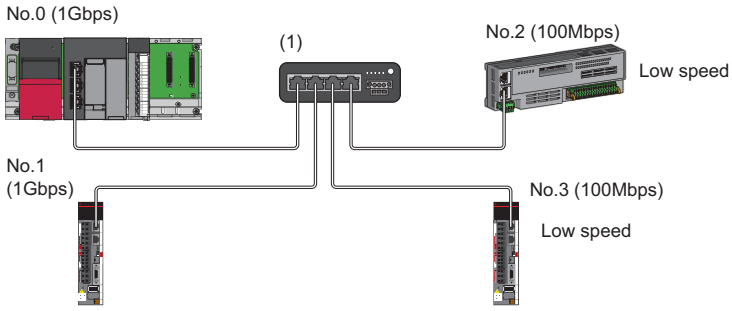
Connection with modules on CC-Link IE TSN with a communication speed of 100Mbps

This section describes the network topology when "Communication Speed" under "Application Settings" is set to "100Mbps".

■Line topology

The network is configured in a line topology.

- Ensure that the communication speed of each module is the same when connecting them.
- When connecting modules with different communication speeds, connect the modules via an industrial switch (CC-Link IE TSN Class B certified).

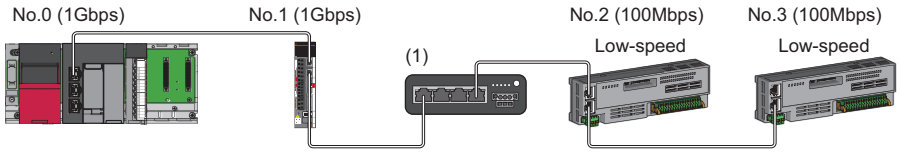


No.0: Master station
No.1, No.2, and No.3: Remote stations

■Star topology

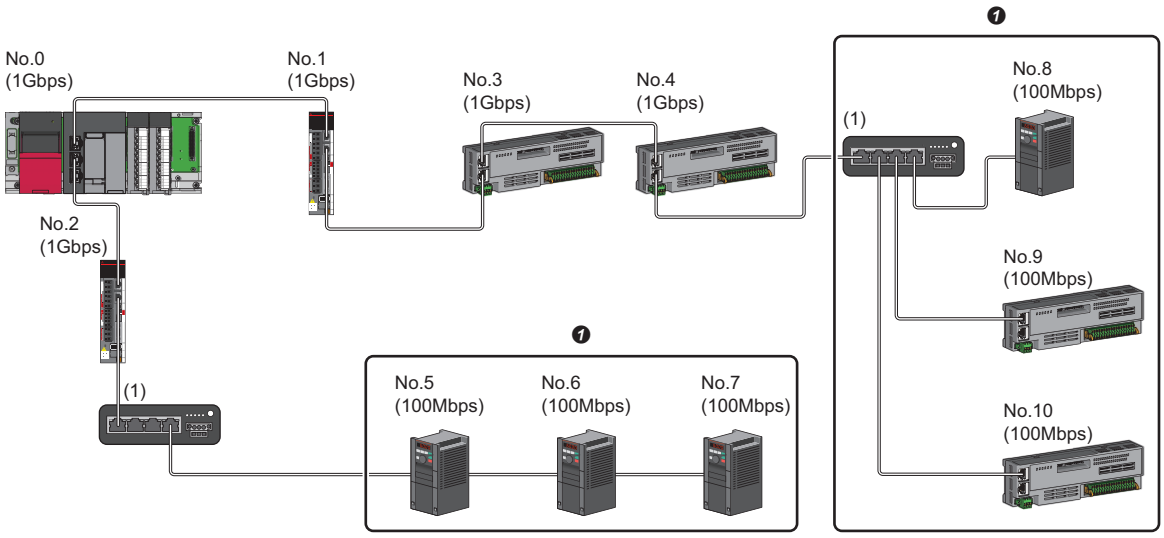
The modules are connected in a star topology via an industrial switch (CC-Link IE TSN Class B certified).

- When the master station with a communication speed of 1Gbps and a remote station with a communication speed of 100Mbps exist in the structure, set "Communication Period Setting" to "Low-Speed" for the remote station with a communication speed of 100Mbps.



No.0: Master station
No.1, No.2, and No.3: Remote stations
(1) Industrial switch (CC-Link IE TSN Class B certified)

■Coexistence of line and star topologies



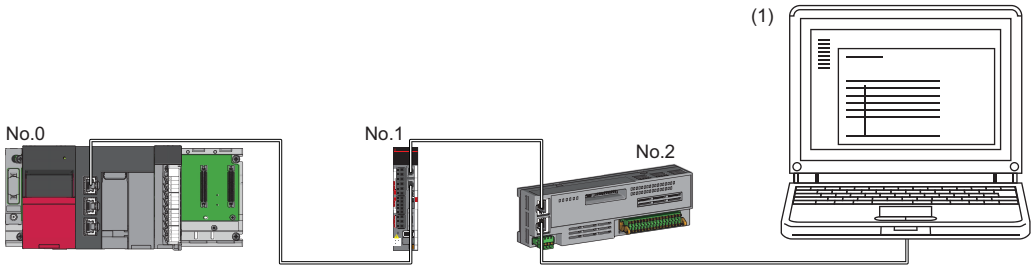
Line and star topologies can be mixed in the same network configuration.

- When the master station with a communication speed of 1Gbps and a device station with a communication speed of 100Mbps exist in the structure, set "Communication Period Setting" to "Low-Speed" for the device station with a communication speed of 100Mbps.

No.0: Master station
No.1, No.2, and No.3: Remote stations
(1) Industrial switch (CC-Link IE TSN Class B certified)

- When the communication speed of the master station is 1Gbps, a connection cannot be established if the total cyclic data size of all device stations on the 100Mbps device side exceeds 2K bytes. This includes the devices with a communication speed of 100Mbps that form a boundary between the communication speed of 1Gbps and 100Mbps.

No.0: Master station
No.1 to 10: Remote stations
(1) Industrial switch (CC-Link IE TSN Class B certified)
❶ Set the total cyclic data size within 2K bytes.



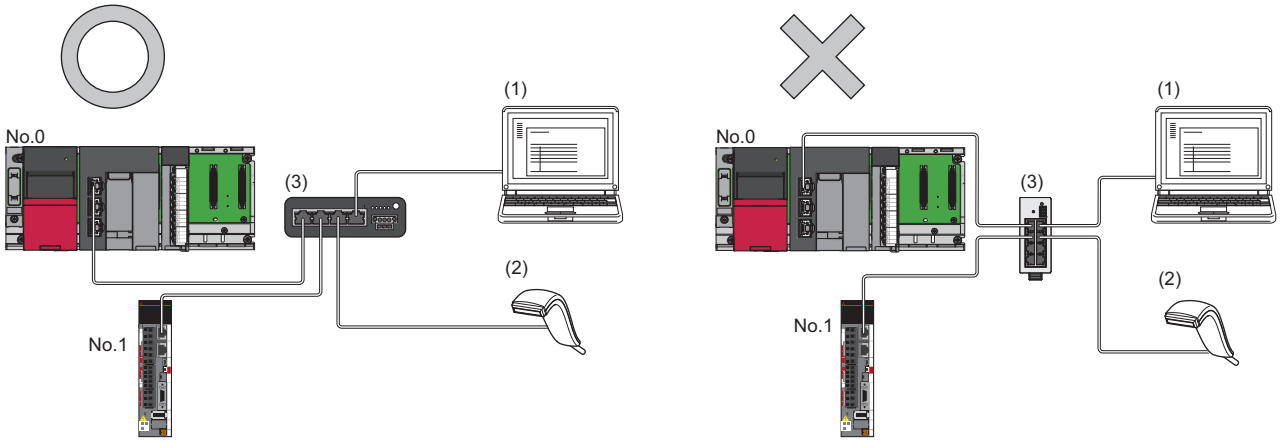
Structure with modules on CC-Link IE TSN and Ethernet devices

Connection with modules on CC-Link IE TSN and Ethernet devices

■Line topology

The network with modules and devices is configured in a line topology. An industrial switch (CC-Link IE TSN Class B certified) is not required for connection.

Connect Ethernet devices to the end of the network.



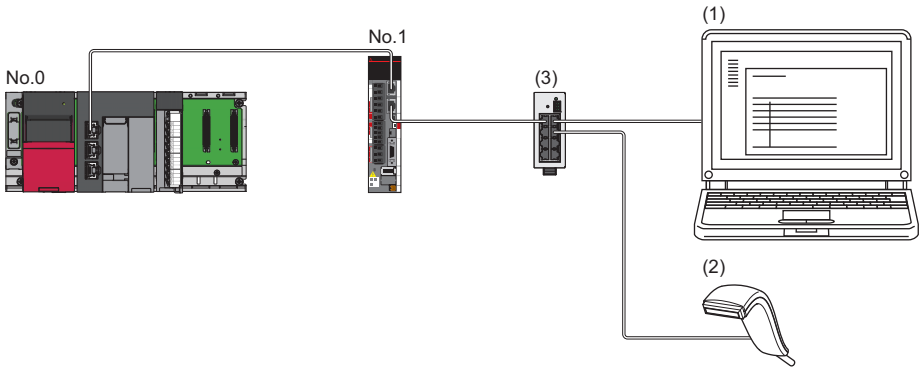
No.0: Master station
No.1 and No.2: Remote stations
(1) Ethernet device (such as a personal computer)

When an error occurs in a device station, the stations connected after the faulty station will be disconnected.

■Star topology

The modules are connected in a star topology via an industrial switch (CC-Link IE TSN Class B certified).

Device stations cannot be connected with an Ethernet switch other than (3) industrial switch (CC-Link IE TSN Class B certified). Line and star topologies should be mixed in the same network configuration.



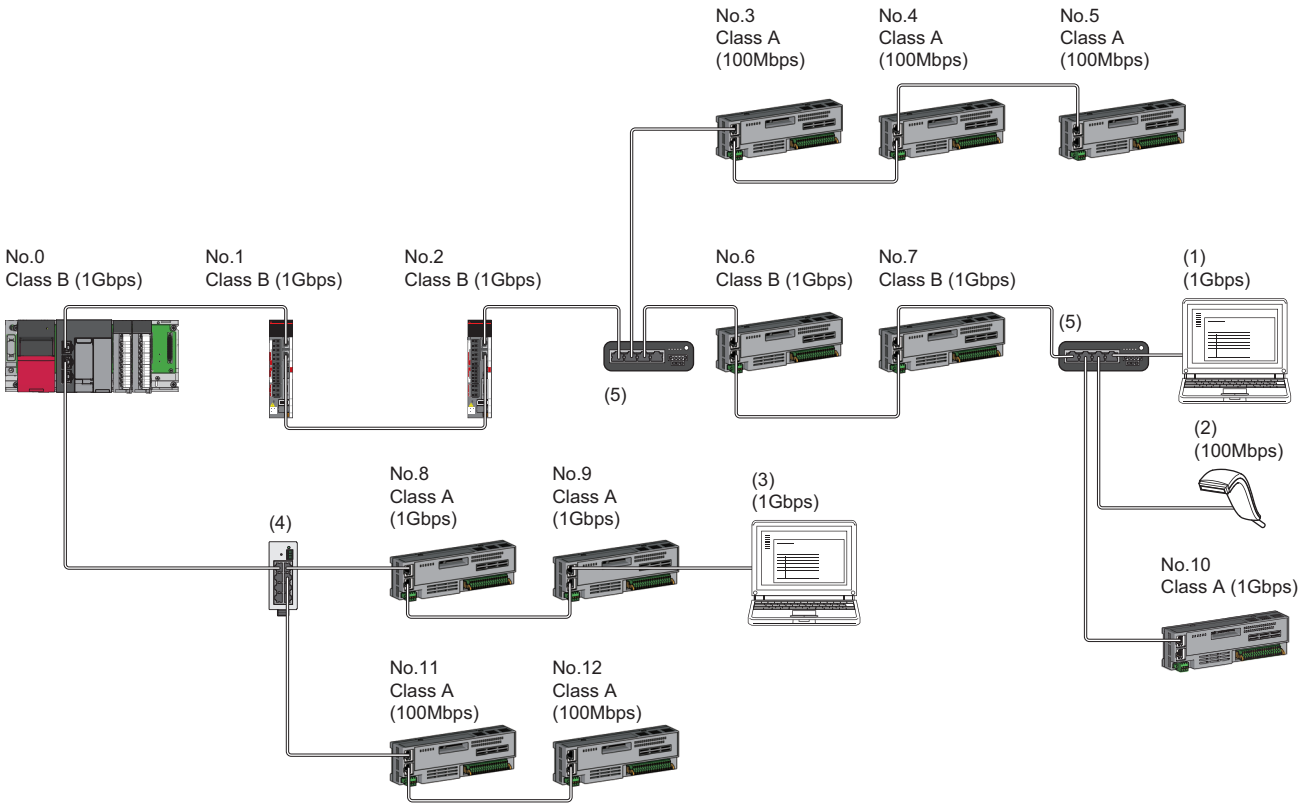
No.0: Master station
No.1: Remote station
(1), (2): Ethernet devices
(3) Industrial switch (CC-Link IE TSN Class B certified)

■Coexistence of line and star topologies

Line and star topologies can be mixed in the same network configuration.

Connect Ethernet devices to the end of the network.

No.0: Master station
No.1: Remote station
(1), (2): Ethernet devices
(3) Ethernet switch



9.6 Structure with CC-Link IE TSN Class B/A Devices

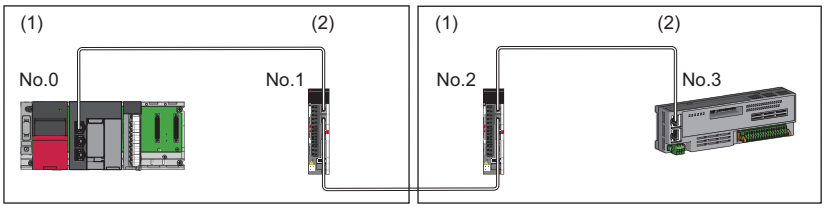
The following diagram shows the system configuration under the conditions below:

- CC-Link IE TSN module is protocol version 2.0 only.
- "Mixture of CC-Link IE TSN Class B/A or CC-Link IE TSN Class A Only" is set for "Connection Device Information" under "Basic Settings" in the engineering tool

If there is a CC-Link IE TSN module that is not protocol version 2.0, refer to the following.

☞ Page 2129 Connection of CC-Link IE TSN Class B/A Devices

No.0: Master station
No.1 to 12: Remote stations
(1), (2), and (3): Ethernet devices
(4) Industrial switch (CC-Link IE TSN Class A certified)
(5) Industrial switch (CC-Link IE TSN Class B certified)
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device



The availability of connection of network configuration devices varies depending on the communication mode and communication speed.

- Unicast mode

☞ Page 179 When the communication speed for the master station is set to 1Gbps

☞ Page 179 When the communication speed for the master station is set to 100Mbps

The following terms are used to describe the terms in the tables referenced.

No.0: Master station
No.1, No.2, and No.3: Remote stations
(1) Device on the master station side (The master station or a device near the master station)
(2) Device on the end side (A device far from the master station)

Structure of unicast mode

The following table lists the availability of connection with a network configuration device when "Communication Mode" under "Application Settings" is set to "Unicast".

When the communication speed for the master station is set to 1Gbps

The following table lists the availability of connection with a network configuration device when "Communication Speed" for the master station is set to "1Gbps".

○: Connection available, △: Connection available via an Ethernet switch, ×: Connection not available

S: Industrial switches (CC-Link IE TSN Class B certified) can be used.

H: Ethernet switches can be used.

Device on the master station side (A device near the master station)		Device on the end side (A device far from the master station)					
		Remote station (CC-Link IE TSN Class B device)		Remote station (CC-Link IE TSN Class A device)		Ethernet device	
		1Gbps	100Mbps	1Gbps	100Mbps	1Gbps	100Mbps
Master station (CC-Link IE TSN Class B device)	1Gbps	○S	△S*1	○SH	△SH*1	○SH	△SH
Remote station (CC-Link IE TSN Class B device)	1Gbps	○S	△S*1*2	○SH	△SH*1	○SH	△SH
	100Mbps	×	○S*1*2	×	○SH*1*2	×	○SH
Remote station (CC-Link IE TSN Class A device)	1Gbps	×	×	○SH	△SH*1	○SH	△SH
	100Mbps	×	×	×	△SH*1	×	○SH

*1 For a device station with a communication speed of 100Mbps, set "Communication Period Setting" to "Low-Speed".

*2 A connection cannot be established if the total cyclic data size of all device stations on the 100Mbps device side exceeds 2K bytes. This includes the devices with a communication speed of 100Mbps that form a boundary between the communication speed of 1Gbps and 100Mbps. (☞ Page 189 Calculation of the total cyclic data size)

Precautions

When using an industrial switch (CC-Link IE TSN Class B certified), be sure to check the specifications of the industrial switch (CC-Link IE TSN Class B certified) on the CC-Link Partner Association website at www.cc-link.org.

When the communication speed for the master station is set to 100Mbps

The following table lists the availability of connection with a network configuration device when "Communication Speed" for the master station is set to "100Mbps".

○: Connection available, ×: Connection not available

S: Industrial switches (CC-Link IE TSN Class B certified) can be used.

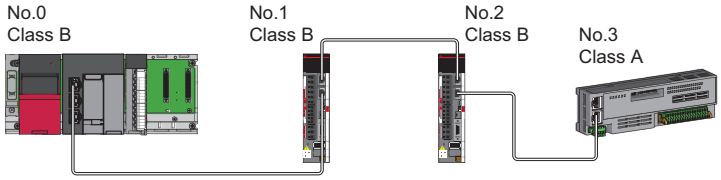
H: Ethernet switches can be used.

Device on the master station side (A device near the master station)		Device on the end side (A device far from the master station)					
		Remote station (CC-Link IE TSN Class B device)		Remote station (CC-Link IE TSN Class A device)		Ethernet device	
		1Gbps	100Mbps	1Gbps	100Mbps	1Gbps	100Mbps
Master station (CC-Link IE TSN Class B device)	100Mbps	×	○S*1	×	○SH	×	○SH
Remote station (CC-Link IE TSN Class B device)	1Gbps	×	×	×	×	×	×
	100Mbps	×	○S*1	×	○SH	×	○SH
Remote station (CC-Link IE TSN Class A device)	1Gbps	×	×	×	×	×	×
	100Mbps	×	×	×	○SH	×	○SH

*1 Set "Communication Period Setting" to "Basic Period" or "Normal-Speed".

Precautions

When using an industrial switch (CC-Link IE TSN Class B certified), be sure to check the specifications of the industrial switch (CC-Link IE TSN Class B certified) on the CC-Link Partner Association website at www.cc-link.org.



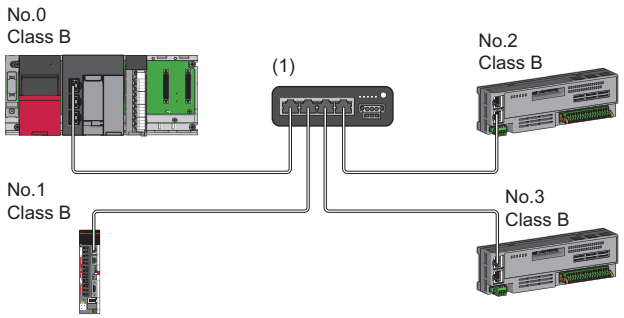
Structure with modules on CC-Link IE TSN only

Connection with modules on CC-Link IE TSN only

■Line topology

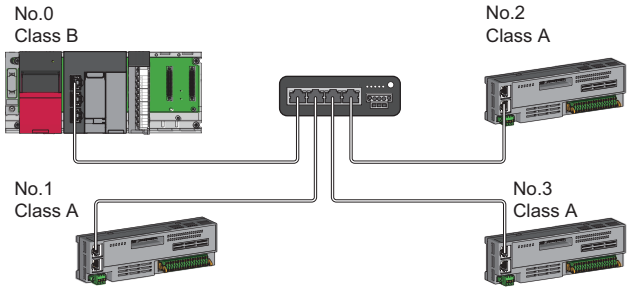
The network is configured in a line topology.

- When connecting a CC-Link IE TSN Class A device, connect to the end of the CC-Link IE TSN Class B device.



No.0: Master station
No.1, No.2, and No.3: Remote stations
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device

■Star topology

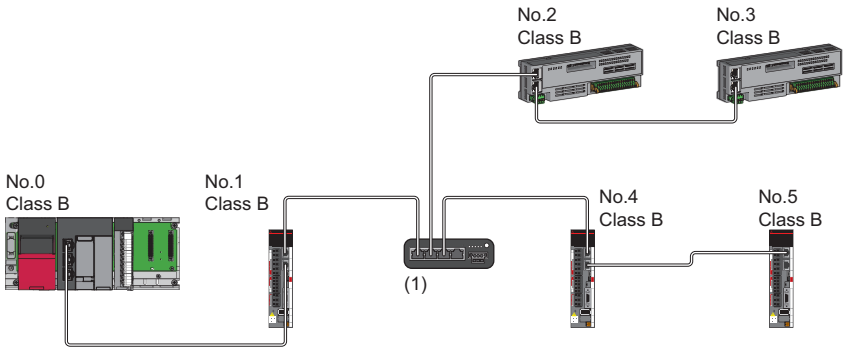


Modules are connected in a star topology via an industrial switch (CC-Link IE TSN certified).

- When connecting a CC-Link IE TSN Class B device in a star topology, use an industrial switch (CC-Link IE TSN Class B certified).

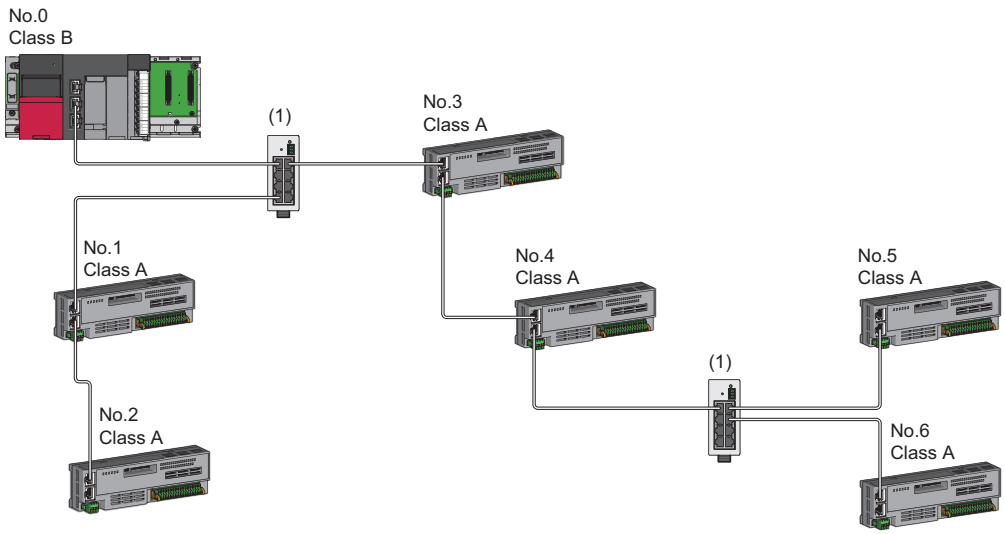
No.0:Master station
No.1, No.2, and No.3: Remote stations
(1) Industrial switch (CC-Link IE TSN Class B certified)
Class B: CC-Link IE TSN Class B device

- When connecting a CC-Link IE TSN Class A device to a CC-Link IE TSN Class B device or a CC-Link IE TSN Class A device to another CC-Link IE TSN Class A device in a star topology, connect them via an industrial switch (CC-Link IE TSN certified).



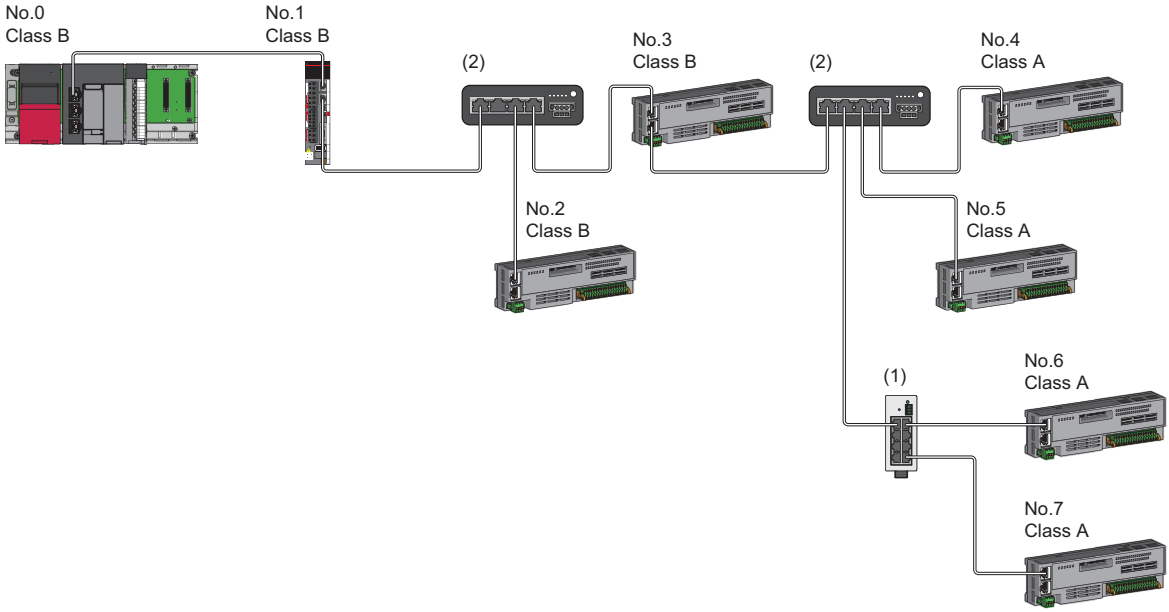
No.0:Master station
No.1, No.2, and No.3: Remote stations
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device

■Coexistence of line and star topologies



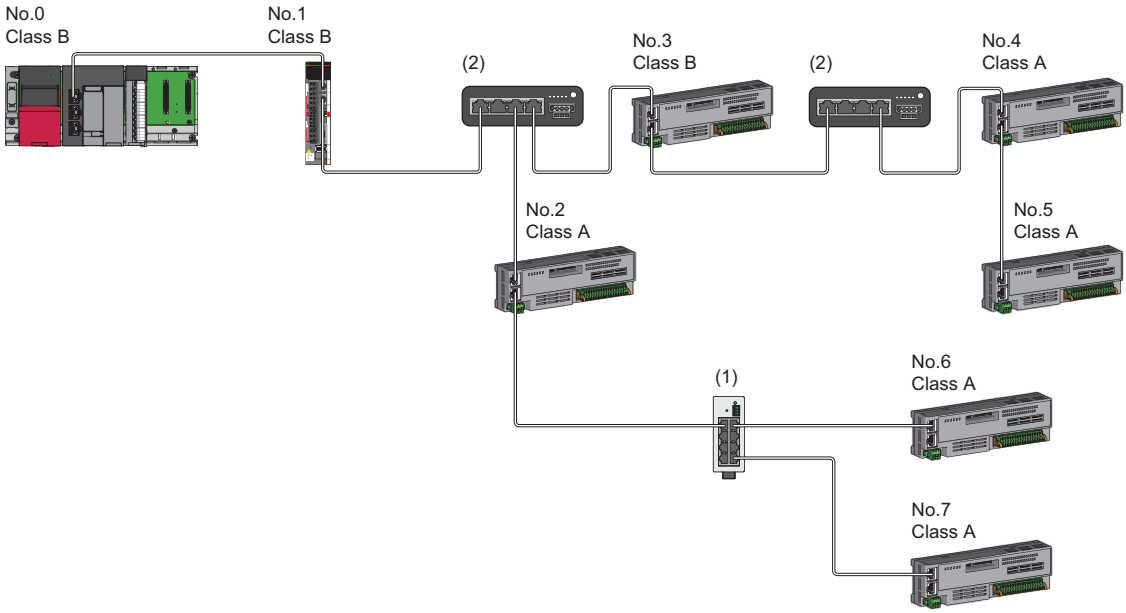
Line and star topologies can be mixed according to the following connection requirements.

- When connecting a CC-Link IE TSN Class B device in a star topology, use an industrial switch (CC-Link IE TSN Class B certified).



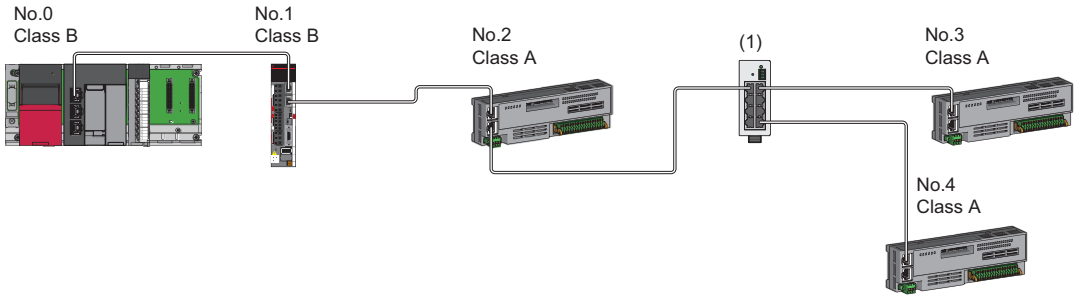
No.0: Master station
No.1 to 5: Remote stations
(1) Industrial switch (CC-Link IE TSN Class B certified)
Class B: CC-Link IE TSN Class B device

- When connecting CC-Link IE TSN Class A devices only in a star topology, use (1) industrial switch (CC-Link IE TSN Class A certified).



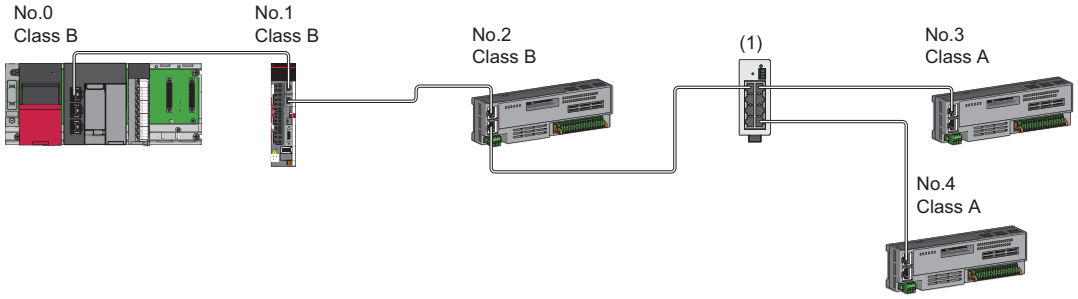
No.0: Master station
No.1 to 6: Remote stations
(1) Industrial switch (CC-Link IE TSN certified)
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device

• In a CC-Link IE TSN Class B/A mixed structure, when connecting a CC-Link IE TSN Class B device in a star topology, connect a CC-Link IE TSN Class A device via an industrial switch (CC-Link IE TSN Class B certified).



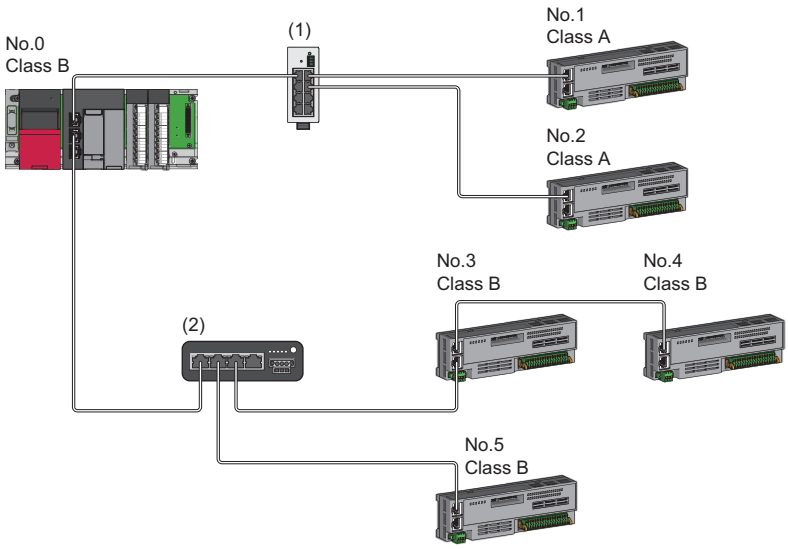
No.0: Master station
No.1 to 7: Remote stations
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device
(1) Industrial switch (CC-Link IE TSN certified)
(2) Industrial switch (CC-Link IE TSN Class B certified)

• In a CC-Link IE TSN Class B/A mixed structure, the CC-Link IE TSN Class A device can be connected from the industrial switch (CC-Link IE TSN Class B certified) between the CC-Link IE TSN Class B devices.



No.0: Master station
No.1 to 7: Remote stations
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device
(1) Industrial switch (CC-Link IE TSN certified)
(2) Industrial switch (CC-Link IE TSN Class B certified)

- In a CC-Link IE TSN Class B/A mixed structure, when connecting a CC-Link IE TSN Class B device in the line topology, connect the CC-Link IE TSN Class A device directly or via (1) industrial switch (CC-Link IE TSN certified).

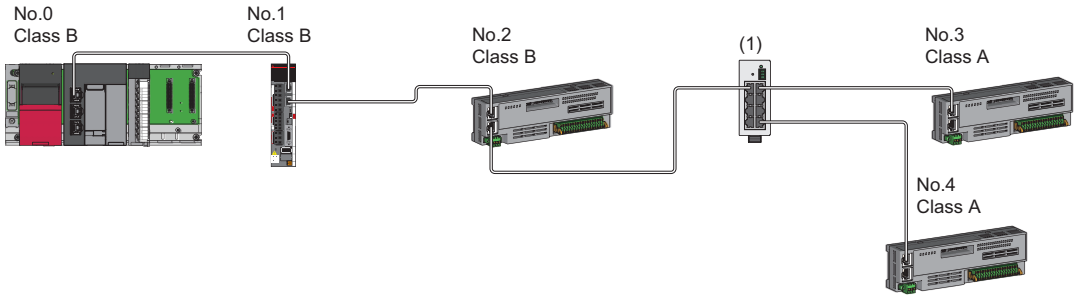


No.0: Master station
No.1 to 4: Remote stations
(1) Industrial switch (CC-Link IE TSN certified)
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device

No.0: Master station
No.1 to 4: Remote stations
(1) Industrial switch (CC-Link IE TSN certified)
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device

- In a CC-Link IE TSN Class B/A mixed structure, when a CC-Link IE TSN Class B device is connected in the star topology using an industrial switch (CC-Link IE TSN Class B certified), the CC-Link IE TSN Class A device station can be connected to another port of the master station directly or via (1) industrial switch (CC-Link IE TSN certified). (Example: P1 to a CC-Link IE TSN Class A device, and P2 to a CC-Link IE TSN Class B device.)

No.0: Master station
No.1 to 5: Remote stations
(1) Industrial switch (CC-Link IE TSN certified)
(2) Industrial switch (CC-Link IE TSN Class B certified)
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device



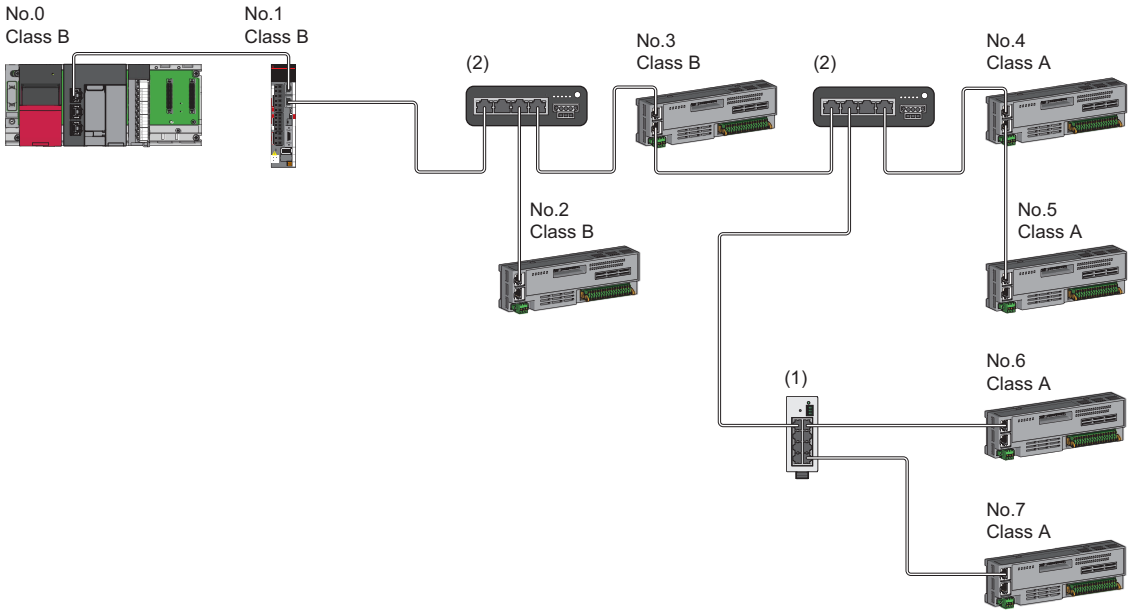
Precautions

In a CC-Link IE TSN Class B/A mixed structure, set whether to use an industrial switch (CC-Link IE TSN Class B certified) in "TSN HUB Setting" of "Connection Device Information" under "Basic Settings". If "TSN HUB Setting" and the system structure differ in whether an industrial switch (CC-Link IE TSN Class B certified) is used, the CC-Link IE TSN Class A device may not perform a data link.

Ex.

Connecting CC-Link IE TSN Class B devices in line topology

- Set "TSN HUB Setting" of "Connection Device Information" under "Basic Settings" to "Not to Use TSN HUB".
- CC-Link IE TSN Class B and CC-Link IE TSN Class A devices are connected using (1) industrial switch (CC-Link IE TSN certified).



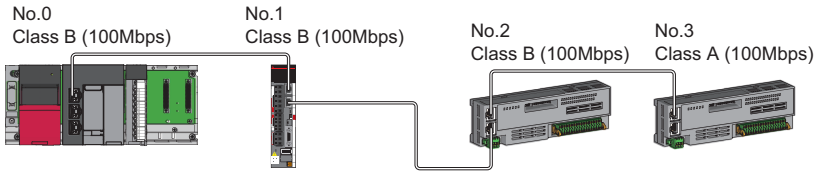
(1) Industrial switch (CC-Link IE TSN certified)
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device

Ex.

Connecting CC-Link IE TSN Class B devices in a star topology

- Set "TSN HUB Setting" of "Connection Device Information" under "Basic Settings" to "Use TSN HUB".
- CC-Link IE TSN Class B and CC-Link IE TSN Class A devices are connected by an industrial switch (CC-Link IE TSN Class B certified).

(1) Industrial switch (CC-Link IE TSN certified)
(2) Industrial switch (CC-Link IE TSN Class B certified)
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device



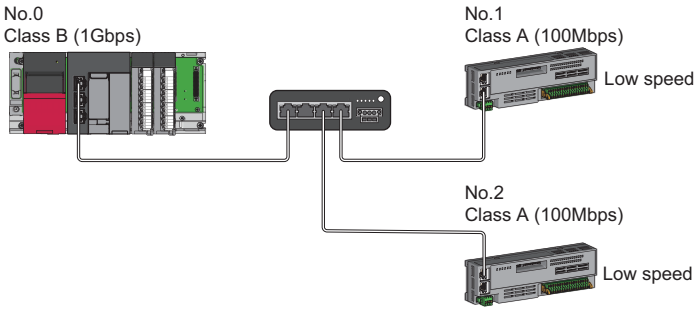
Connection with modules on CC-Link IE TSN with a communication speed of 100Mbps

This section describes the network topology when "Communication Speed" under "Application Settings" is set to "100Mbps".

■Line topology

The network is configured in a line topology.

- Adjust the communication speed of the module.
- When connecting modules with different communication speeds, connect the modules via an industrial switch (CC-Link IE TSN certified).

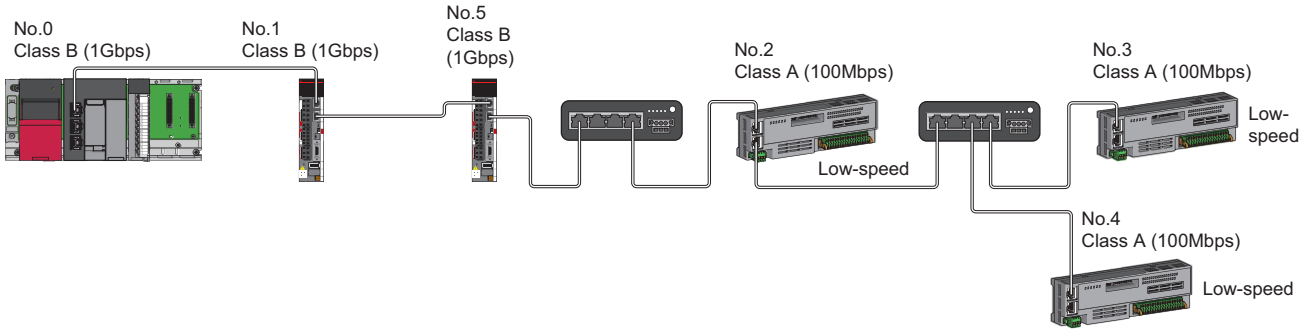


No.0: Master station
No.1, No.2, and No.3: Remote stations
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device

■Star topology

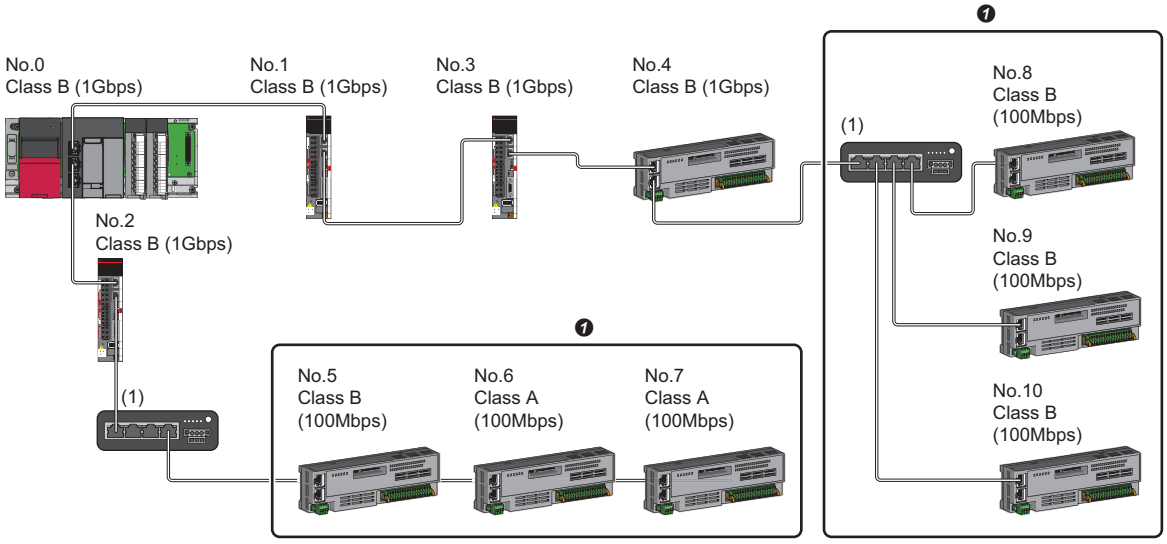
Modules are connected in a star topology via an industrial switch (CC-Link IE TSN certified).

- When the master station with a communication speed of 1Gbps and a device station with a communication speed of 100Mbps exist in the structure, set "Communication Period Setting" to "Low-Speed" for the device station with a communication speed of 100Mbps.



No.0: Master station
No.1 and No.2: Remote stations
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device

■Coexistence of line and star topologies



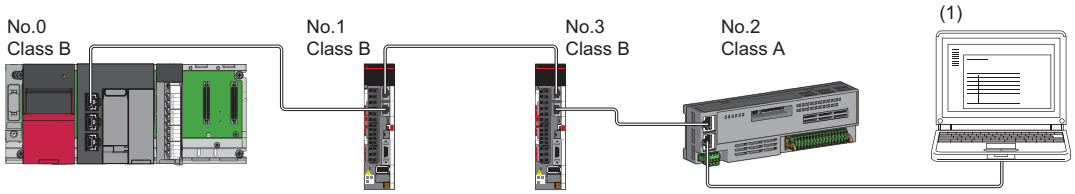
Line and star topologies can be mixed in the same network configuration.

- When the master station with a communication speed of 1Gbps and a device station with a communication speed of 100Mbps exist in the structure, set "Communication Period Setting" to "Low-Speed" for the device station with a communication speed of 100Mbps.

No.0: Master station
No.1 to 5: Remote stations
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device

- When the communication speed of the master station is 1Gbps, a connection cannot be established if the total cyclic data size of all device stations on the 100Mbps device side exceeds 2K bytes. This includes the devices with a communication speed of 100Mbps that form a boundary between the communication speed of 1Gbps and 100Mbps.

No.0: Master station
No.1 to 10: Remote stations
(1) Industrial switch (CC-Link IE TSN Class B certified)
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device
❶ Set the total cyclic data size within 2K bytes.

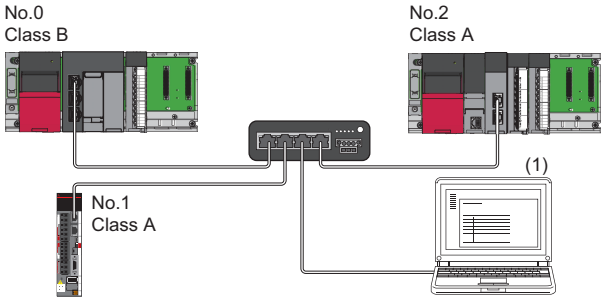


Structure with modules on CC-Link IE TSN and Ethernet devices

Connection with modules on CC-Link IE TSN and Ethernet devices

■Line topology

The network with modules and devices is configured in a line topology. An Ethernet switch is not required for connection.

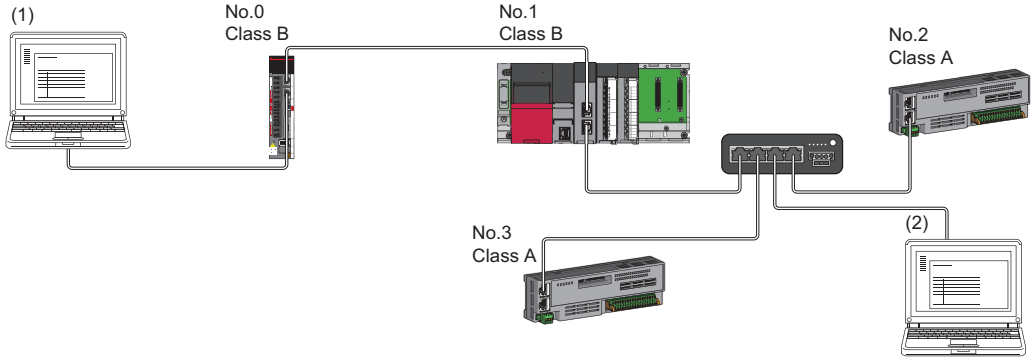


Connect Ethernet devices to the end of the network.

No.0:Master station
No.1, No.2, and No.3: Remote stations
(1) Ethernet device
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device

■Star topology

Modules or Ethernet devices are connected in a star topology via an industrial switch (CC-Link IE TSN certified).



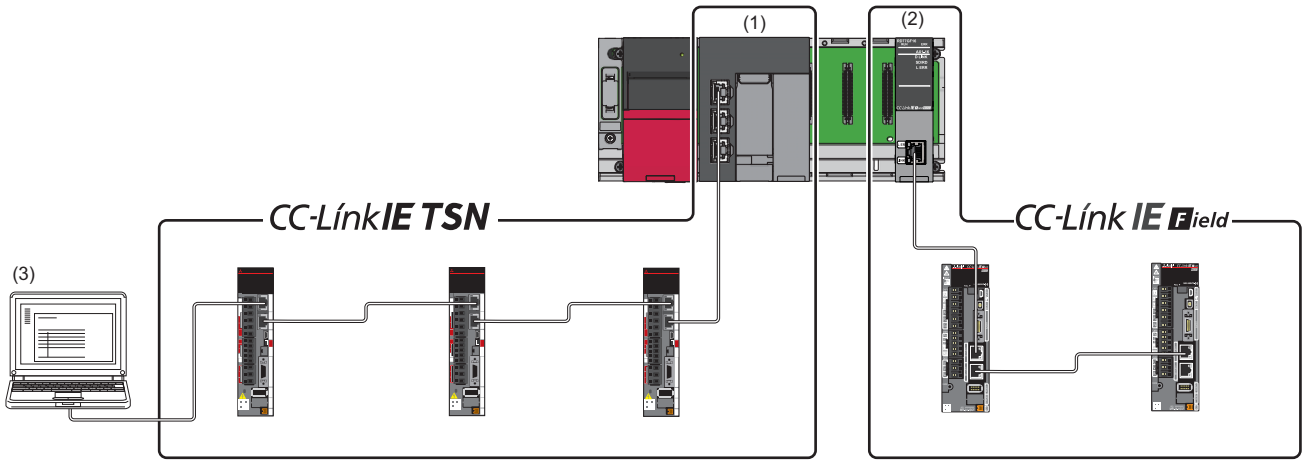
No.0: Master station
No.1 and No.2: Remote stations
(1) Ethernet device (such as a personal computer, vision sensor, and bar code reader)
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device

■Coexistence of line and star topologies

Line and star topologies can be mixed according to the following connection requirements.

- Connect Ethernet devices at the end of line topology.
- When connecting the Ethernet devices in a star topology, connect them to an industrial switch (CC-Link IE TSN certified).

No.0:Master station
No.1, No.2, and No.3:Remote stations
(1), (2): Ethernet devices
Class A: CC-Link IE TSN Class A device
Class B: CC-Link IE TSN Class B device



9.7 Structure of the CC-Link IE TSN and CC-Link IE Field Network

Set different network numbers to the controller and the CC-Link IE Field compatible network module, and mount the master stations of each network on the same base unit.

Connect Ethernet devices to the end of the network.

For details on CC-Link IE Field Network, refer to the following.

- MELSEC iQ-R Ethernet/CC-Link IE User's Manual (Startup)
- MELSEC iQ-R CC-Link IE Field Network User's Manual (Application)

(1) Master station (Network No.1)
(2) Master station (Network No.3)
(3) Ethernet device

Point

The communication data of the CC-Link IE TSN and CC-Link IE Field Network are transferred between master stations.

9.8 Precautions for System Configuration

Devices connected to the same network

Do not connect the devices as described below. Doing so may cause the disconnection of all stations.

- A module on CC-Link IE TSN and a device having different network types (such as CC-Link IE Controller Network or CC-Link IE Field Network) other than an Ethernet device are connected to the same network.
- A module on CC-Link IE TSN and an Ethernet device (such as a personal computer), both of which are on different networks, are connected to one Ethernet switch.

Adding a device station with no IP address setting

In a line topology, do not connect the device station with no IP address setting at a place other than the end of the network. A data link may not be performed in the device stations after the device station with no IP address setting.

CC-Link IE TSN/CC-Link IE Field diagnostics

If the following operations are performed, the actual network configuration and the network map of the CC-Link IE TSN/CC-Link IE Field diagnostics may be different.

Network configuration	Operation
Star topology	• Powering off and on a device station or Ethernet switch • Connecting/disconnecting an Ethernet cable connected to the Ethernet switch • Disconnecting an Ethernet cable and connecting it to another device station or an Ethernet switch • Disconnecting 10 or more stations, or half or more the number of device stations in the system • Changing the network topology when adding a device station
Line topology	• Simultaneously powering off or on multiple stations • Simultaneously connecting/disconnecting Ethernet cables to/from multiple stations (When a data link faulty station returns, a data link error will occur in all the stations.) • Disconnecting 10 or more stations, or half or more the number of device stations in the system • Changing the network topology when adding a device station

Point

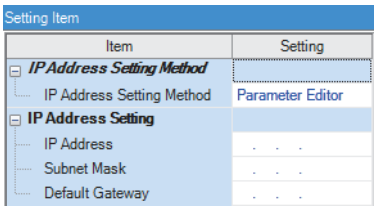
The actual network configuration and network map can be matched by executing the network map update of the CC-Link IE TSN/CC-Link IE Field diagnostics. For details, refer to the following.

☞ Page 1697 CC-Link IE TSN/CC-Link IE Field diagnostics

Calculation of the total cyclic data size

The following shows the calculation formula of the total cyclic data size. The part of the variable surrounded by double quotes (" ") is the setting value of "Network Configuration Settings" under "Basic Settings".

Total cyclic data size = 256 + (106 × Number of remote stations) + (Number of "RX Setting" points ÷ 8) + (Number of "RWr Setting" points × 2) [byte]



10 Ethernet SYSTEM CONFIGURATION

This chapter describes the system configuration for connecting the devices using Ethernet with the controller.

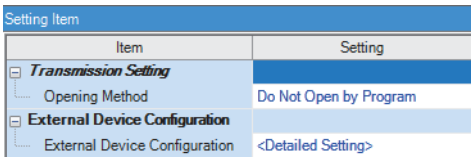
10.1 Required Settings

This section describes the parameter settings required for communications with other stations.
Set the parameters such as the IP address of the controller.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [Module Parameter (Port 3: Ethernet)] ⇨ [Module Parameter (Ethernet)] ⇨ [Required Settings]

Item	Description	Reference
IP Address Setting Method	Select the method for setting the IP address of own station.	Page 1432 IP Address Setting Method
IP Address Setting	Set the IP address of the own station. Set the IP address class within the range of classes A, B and C.	Page 190 IP Address Setting

IP Address Setting



Set the IP address of the own station.

Item		Description	Setting range
IP Address Setting	IP Address	Set the IP address of the own station. Set the IP address class within the range of classes A, B and C. Set the external device to the same class and subnet address of the controller of the own station for communications. Consult with the network manager for the IP address setting. When the parameters are written without setting the IP address, the address 192.168.3.39 is set.	• Blank • 0.0.0.1 to 223.255.255.254 (Default: Blank)
	Subnet Mask	Set the subnet mask pattern of the default gateway when setting the IP address of the default gateway and communicating with an external device on another network via a router. All the devices on a subnetwork must have the same subnet mask. This setting is not required when communicating in single network.	• Blank • 0.0.0.1 to 255.255.255.255 (Default: Blank)
	Default Gateway	Set the IP address of the default gateway (the device which the own node passes through to access a device of another network). Set the value that satisfies the following conditions. • The IP address class is any of A, B, and C. • The subnet address of the default gateway is the same as the subnet address of the controller of the own station. • The host address bits are not all "0" or all "1".	• Blank • 0.0.0.1 to 223.255.255.254 (Default: Blank)

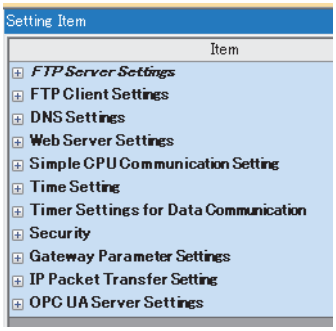
10.2 Basic Settings

Set the connection with the external device.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [Module Parameter (Port 3: Ethernet)] ⇨ [Module Parameter (Ethernet)] ⇨ [Basic Settings]

Item	Description	Reference
Transmission Setting	Configure the settings for Ethernet communications.	Page 191 Transmission Setting
External Device Configuration	Configure the settings for communications with external devices.	Page 194 "Ethernet Configuration" Window (External Device Configuration Setting)

Transmission Setting



Configure the settings for Ethernet communications.

Item	Description	Setting range
Opening Method	Select how to open the connection.	• Do Not Open by Program • Open by Program (Default: Do Not Open by Program)

10.3 Application Settings

Configure the settings for communications with external devices.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [Module Parameter (Port 3: Ethernet)] ⇨ [Module Parameter (Ethernet)] ⇨ [Application Settings]

Item	Description	Reference
FTP Server Settings	Configure settings related to the FTP server.	Page 1347 FTP server settings
FTP Client Settings	Configure settings related to the FTP client.	Page 1375 FTP client settings
DNS Settings	Configure settings related to the DNS server.	Page 1437 DNS settings
Web Server Settings	Configure settings related to the Web server function.	Page 1384 Web server settings
Simple CPU Communication Setting	Configure settings related to simple CPU communications.	Page 193 Simple CPU Communication Setting
Time Setting	Automatically performs time setting of the controller by collecting clock data from the time information server (SNTP server) on the LAN.	Page 1935 Clock Data
Timer Settings for Data Communication	Set the timer to be used by each function.	Page 1771 Timer settings for data communication
Security	Configure settings related to security.	Page 1534 LIST OF SECURITY FUNCTIONS
Gateway Parameter Settings	Set gateway parameters to communicate with an external device connected to other Ethernet via a router.	Page 193 Gateway Parameter Settings
IP Packet Transfer Setting	Configure settings related to the IP packet transfer function.	Page 193 IP Packet Transfer Setting
OPC UA Server Settings	Configure settings related to the OPC UA server function.	Page 1416 OPC UA Server Settings

Simple CPU Communication Setting

Configure settings related to simple CPU communications.

Item	Description	Setting range
To Use or Not to Use Simple CPU Communication	Select whether to use the simple CPU communication or not.	• Not to Use • Use (Default: Not Use)
Simple CPU Communication Setting	Configure settings for simple CPU communications.	—

Gateway Parameter Settings

Set gateway parameters to communicate with an external device connected to other Ethernet via a router.

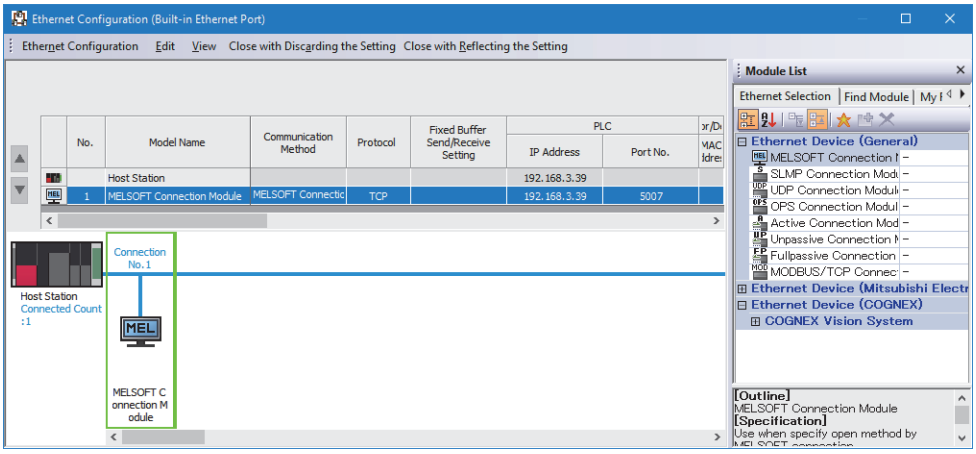
Item			Description	Setting range
Gateway Other Than Default Gateway			Set whether or not to use a gateway other than the default gateway.	• Not Use • Use (Default: Not Use)
Gateway Information	No.1 to No.8	Gateway IP Address	Set the IP address of the gateway other than the default gateway.	• Blank • 0.0.0.1 to 223.255.255.254 (Default: Blank)
		Subnet Address	Set the network address or subnet address of the external device when communicating with it through a gateway other than the default gateway.	• Blank • 0.0.0.1 to 223.255.255.254 (Default: Blank)

IP Packet Transfer Setting

Configure settings related to the IP packet transfer function.

Item	Description	Setting range
IP Packet Transfer Function	Select whether to use the IP packet transfer function.	• Not Use • Use (Default: Not Use)

10.4 "Ethernet Configuration" Window (External Device Configuration Setting)



Set the method and protocol used for communicating with external devices.
This setting can be used only for Ethernet ports. (☞ Page 50 MX-R Model)

Setting method

The procedure for setting the external device to be connected is shown below.

1. Select the external device to be connected in "Module List" and drag it to the list of devices or device map area.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [Module Parameter (Port 3: Ethernet)] ⇨ [Module Parameter (Ethernet)] ⇨ [Basic Settings] ⇨ [External Device Configuration]

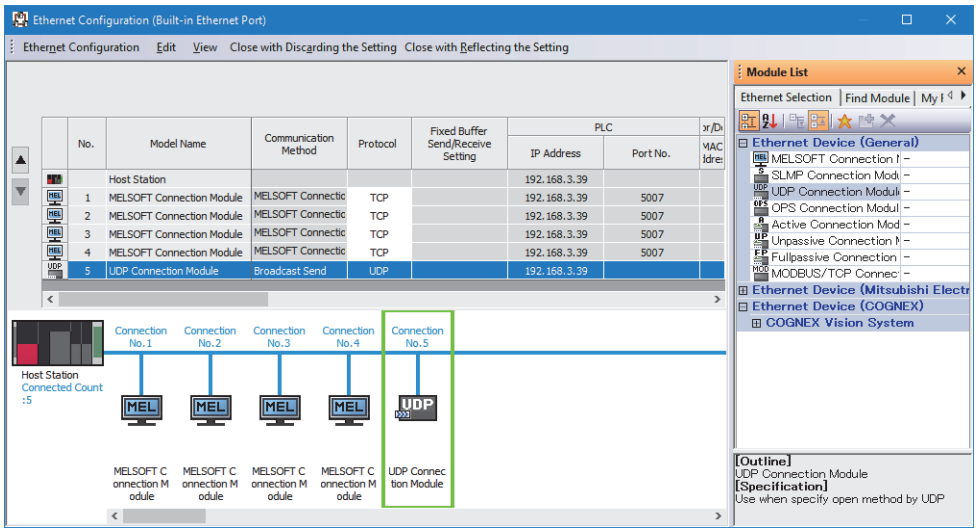
2. Set the required items. The required items vary depending on the selected external device.

3. Select [Close with Reflecting the Setting] to finish the "External Device Configuration" settings.

Point

Since encrypted communications need the protocol (TLS, DTLS) and port number to be set, apply the external device configuration settings. In addition, the same port number cannot be used for multiple connections.

For unencrypted communications, the system dedicated connection can be used to connect to MELSOFT products and GOT. The number of connectable modules by protocol is listed below.



- TCP connection: (Maximum number of connectable modules in "External Device Configuration") - (Number set for a communication means other than "MELSOFT connection") + 1
- UDP connection: Simultaneous communication is possible for up to 120 modules by Ethernet port and up to 8 modules by CC-Link IE TSN port.

Restriction

Set external devices from the connection No.1.

To use specific connection number, set "MELSOFT Connection Module" in the connection number not used. (Set "Protocol" to "TCP".)

• When only the connection No.5 is used.

Setting items

Item		Description	Setting range
No.		Connection number for distinguishing settings for each user connection.	The number is set in the range in order from 1 up to 64.
Model Name		The name of the external device is displayed.	—[*1]
Communication Method		Set the method for communications with the external device. • Broadcast Send: Sends the same data to an unspecified number of devices all at once. • Broadcast Receive: Receives data sent by broadcast. • Predefined Protocol: Communications according to the protocol of the external device • Socket Communication: Send and receive arbitrary data. • MELSOFT Connection: Communicate with MELSOFT products and a GOT. Set it to reserve a connection for MELSOFT. • SLMP: Communications that use SLMP (MC protocol) commands to access controller files and read/write data from external devices	• Broadcast Send • Broadcast Receive • Predefined Protocol • Socket Communication • MELSOFT Connection • SLMP
Protocol		Select the communication protocol for the external device. • TCP: Secures a connection that allows one-to-one communication with the external device. Data arrival is checked. • UDP: Secures a connection that allows one-to-many communications with the external device. Data arrival is not checked. • TLS: Secures a connection for encrypted communications with the external device. Data arrival is checked. • DTLS: Secures a connection for encrypted communications with the external device. Data arrival is not checked.	• TCP • UDP • TLS • DTLS (Default: TCP)
PLC	IP Address	The IP address of the own node, which is set in "IP Address" of "Required Settings", is displayed.	0.0.0.1 to 223.255.255.254
	Port No.	Set the port number for each connection on the controller.	1 to 4999, 5010 to 65534 (Default: Blank)[*2]
Sensor/ Device	MAC Address	The MAC address of the device supporting iQSS is displayed when using the automatic detection of connected devices.	—
	Host Name	Set the name for identifying the device supporting iQSS. This setting is available only for the devices supporting iQSS which were detected by automatic detection of connected devices.	63 characters maximum The following one-byte characters can be used. • Number (0 to 9) • Alphabetical character (a to z, A to Z) • Hyphen (-) • Period (.) • Colon (:) • Underscore (_) (Default: Blank)[*2]
	IP Address	Set the IP address of the external device.	0.0.0.1 to 223.255.255.254 (Default: Blank)[*2]
	Port No.	Set the port number of the external device. Set "65535" to set all the port numbers as the target of data receive.	1 to 65534, 65535 (Default: Blank)[*2]
	Subnet Mask	Set the subnet mask of the device supporting iQSS. This setting is available only for the devices supporting iQSS which were detected by automatic detection of connected devices.	192.0.0.0 to 255.255.255.252 (Default: Blank)[*2]
	Default Gateway	Set the default gateway of the device supporting iQSS. This setting is available only for the devices supporting iQSS which were detected by automatic detection of connected devices.	0.0.0.1 to 223.255.255.254 (Default: Blank)[*2]
Existence Confirmation		Select the method of alive check which is performed when the controller has not communicated with the external device for a certain period of time. When the controller cannot communicate with the external device, the connection will be closed. (☞ Page 198 Existence confirmation)	• KeepAlive • UDP • Do not confirm existence

Item		Description	Setting range
Connection Monitoring Timer	Setting	Set the watch time when closing a connection in TCP or TLS communications. If a communication request is not made from the external device within the set time after the connection is established, a timeout error will occur and the connection will be closed. (☞ Page 199 Connection monitoring timer)	• — • Disable • Enable
	Time	Set the time for the connection monitoring timer.	• — • ms: 100 to 16383000 (in increments of 100ms) • s: 1 to 16383
	Unit	Select a unit of measurement for the connection monitoring timer.	• — • s • ms

*1 OPS connected devices and MODBUS/TCP connected devices cannot be set.

*2 When the automatic detection of the connected devices is executed, the values read from the connected devices will be the default.

Point

Comment can be set on the "Properties" window displayed by right-clicking the module in the list of devices or device map area and selecting "Properties". The following can be performed depending on the selected device.

- Changing the image
- Creating association with a file or application

Encrypted communication protocol

Select TLS or DTLS for encrypted communications with an external device.

The combinations of "Model Name" and "Communication Method" for which TLS or DTLS can be selected are shown below.

○: Selectable, ×: Not selectable

Model name	Communication method	Selectable protocol	
		TLS	DTLS
MELSOFT Connection Module	MELSOFT Connection	○	○
SLMP Connection Module	SLMP	○	○
UDP Connection Module	Broadcast Send	×	×
	Broadcast Receive	×	×
	Socket Communication	×	×
	Predefined Protocol	×	×
Active Connection Module	Socket Communication	○	○
	Predefined Protocol	×	×
Unpassive Connection Module	Socket Communication	○	○
	Predefined Protocol	×	×
Fullpassive Connection Module	Socket Communication	○	○
	Predefined Protocol	×	×

For precautions on encrypted communications, refer to the following.

☞ Page 1558 Encrypted Communication Function

Point

Right-click the SLMP connected device item. From the menu displayed, select "Change Module" to change "Model Name".

If the "Protocol" before change is TLS or DTLS, TLS is changed to TCP and DTLS to UDP.

Existence confirmation

When the controller has not communicated with the external device for a certain period of time while the connection is open, this function checks whether the external device is alive by sending an alive check message to the device and waiting for the response.

The following table lists the details on alive check.

Item	Applicable protocol	Description
KeepAlive	• TCP • TLS	This method is used for a connection opened using TCP. The controller performs an alive check by sending an ACK message for alive check to the external device with which communications have not been performed for a certain period of time and waiting to check whether the response is received. The connection will be automatically closed when the open state is not continued.*1
UDP	• UDP*3 • DTLS	This method is used for a connection opened using UDP. The controller performs an alive check by sending the PING command (ICMP echo request/response function) to the external device with which communications have not been performed for a certain period of time and waiting to check whether the response is received.*2
Do not confirm existence	• TCP • UDP • TLS • DTLS	Alive check is not performed.

*1 The connection may be disconnected if the external device does not support the TCP KeepAlive function (response to a KeepAlive ACK message).

*2 The controller automatically sends an echo response packet when it receives a PING echo request command. (It sends a response to the received PING command even if the connection used in the data communications with the external device is closed.)

*3 When "Protocol" of the SLMP connection device is set to "UDP" in the "Ethernet Configuration" window, the destination cannot be specified. Therefore, the alive check will not be executed even if "Existence Confirmation" is set to "UDP".

Point

If a response message cannot be received from the external device (or if an error has been detected) using the alive check function, the following are performed.

- The corresponding connection will be forcibly closed. (The line is disconnected.) Open the connection again using a user program.
- Open completion signal is turned off, and the error code is stored in the buffer memory areas.

Connection monitoring timer

Set the watch time when closing a connection in TCP or TLS communications where the controller is the server.

If a communication request or communication response is not made within the set time while the connection is established, a timeout error will occur and the connection will be closed.

The combinations for which the connection monitoring timer can be set are shown below.

○: Selectable, ×: Not selectable

Model	Communication method	Selectable protocol	
		TCP	TLS
MELSOFT Connection Module	MELSOFT Connection	×*1	○
SLMP Connection Module	SLMP	○	○
Unpassive Connection Module*2	Socket Communication	○	○
	Predefined Protocol	○	×
Fullpassive Connection Module*2	Socket Communication	○	○
	Predefined Protocol	○	×

*1 If TCP is set for the MELSOFT connection, use the system dedicated connection.
The controller can connect to MELSOFT products and GOT using the system dedicated connection without configuring the external device connection configuration setting.

*2 When the communication method is socket communication or communication protocol connection, the connection is closed when a timeout error occurs in the connection monitoring timer. Therefore, to accept the connection again, the connection needs to be opened.

Point

DTLS communications operate with a watch time of 900 seconds.

■Precautions

Set the connection monitoring timer to a value greater than the send/receive interval of communication requests and communication responses.

If a value smaller than the send/receive interval is set, the connection monitoring timer may close the connection during communication, resulting in communication failure. If the connection is closed by the connection monitoring timer, extend the time.

Ex.

For MELSOFT connection:

- Connection monitoring timer setting value > Communication time check setting value

10.5 Connection with MELSOFT Product and GOT

Programming and monitoring of the programmable controller with the engineering tool, and monitoring and testing of the programmable controller from the GOT can be performed via Ethernet. This function enables remote operations using Ethernet's long-distance connection and high-speed communications.
This section describes the methods of connecting the controller to MELSOFT products (such as engineering tool and MX Component) and a GOT.
○: Supported, ×: Not supported

Port*1	Direct connection	Specifying IP address	Searching the CPU module on the network*2
Port for CC-Link IE TSN	×	×	×
Port for Ethernet	○	○	○

*1 For the port allocation, refer to the following.
☞ Page 50 MX-R Model
*2 Encrypted communications are not supported.

Point

- Encrypt communications whose communication route crosses the trust boundary.
- For the procedures to connect the controller and a GOT, refer to the following.

📖 Manual for the GOT used

Restriction

The following functions cannot be used when the controller and an engineering tool are connected via an industrial switch. To use the functions, connect them directly or with a USB cable.

- Ethernet diagnostics
- CC-Link IE TSN/CC-Link IE Field diagnostics
- CC-Link IE Control Diagnostics

Direct connection

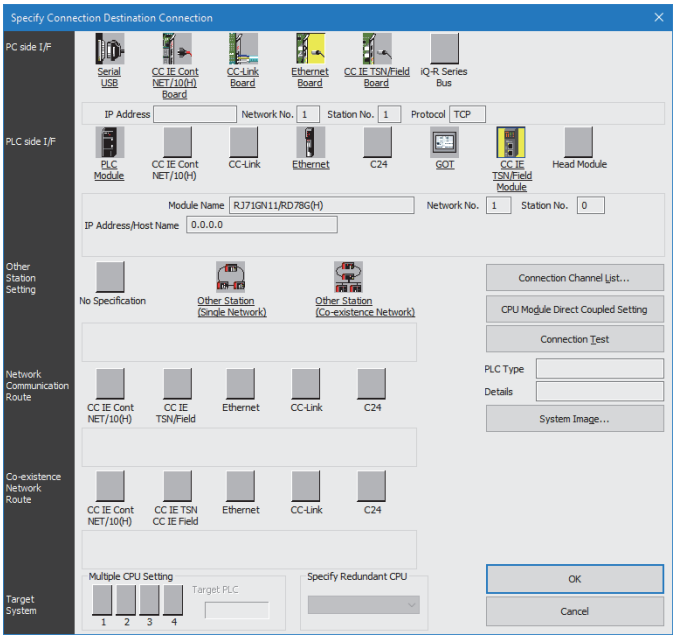
The controller and engineering tool can be directly connected with a single Ethernet cable without using an industrial switch. When direct connection is made, communications are possible without setting the IP address or host name in the "Specify Connection Destination Connection" window. (Communicate using broadcast communications)

The availability of unencrypted/encrypted communications with MELSOFT products and GOT are shown below.

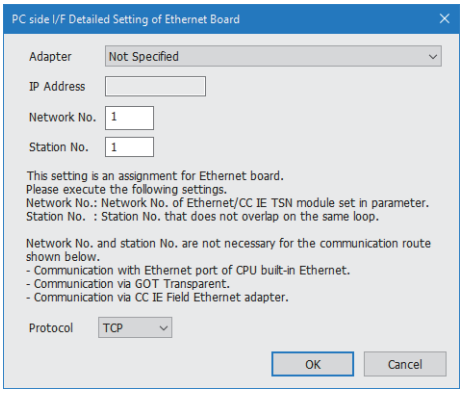
○: Available, ×: Not available

Connection device*1	Whether unencrypted communications are available		Whether encrypted communications are available	
	Port for CC-Link IE TSN	Port for Ethernet	Port for CC-Link IE TSN	Port for Ethernet
MELSOFT products	×	○	×	×
GOT	×	×	×	×

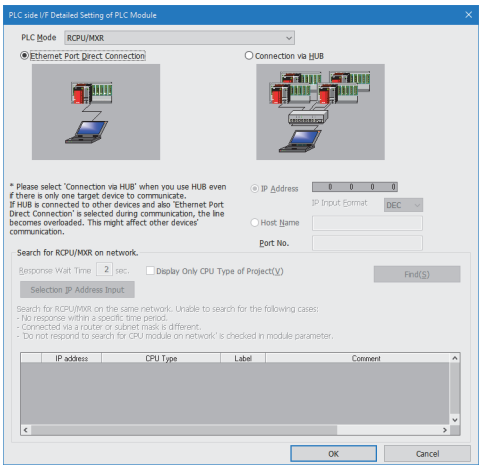
*1 For the port allocation, refer to the following.
☞ Page 50 MX-R Model



Point



To prohibit direct connection via Ethernet cable, set "MELSOFT Direct Connection Port" in "Security" of "Basic Settings" under "Module Parameter (Common Setting)" to "Close".



Setting method

Set in the "Specify Connection Destination Connection" window.

[Online] ⇨ [Current Connection Destination]

1. Select "Ethernet Board" for "PC side I/F".
2. Double-click "Ethernet Board" to display the "PC side I/F Detailed Setting of Ethernet Board" window.
3. Set the operating protocol. Set the protocol according to the settings for the controller.

4. Set "PLC side I/F" to "PLC Module".
5. Double-click "PLC Module" to display the detailed setting window.
6. Select "Ethernet Port Direct Connection" for the connection method.

Point

It can also be set with the [CPU Module Direct Coupled Setting] button on the "Specify Connection Destination Connection" window.

Precautions

■Connection with LAN line

Do not connect with a LAN line and set direct connection. Data will be sent to all external devices on the LAN line, so this setting will cause the line load to increase and will affect communications with other external devices.

■Connections that are not direct connections

- Do not use a configuration in which the controller and the external device are connected to an industrial switch. A direct connection is not established if an industrial switch is used.
- When creating a network connection on the personal computer side, communications with a direct connection is not possible if two or more Ethernet ports are set to "Enable". Review the personal computer settings so that only the Ethernet port for the direct connection is set to "Enable", and the other Ethernet ports are set to "Disable".
- Use only one engineering tool for the personal computer.

■Conditions that disable communications using direct connection

Communications with a direct connection may be disabled if the following conditions apply. If communications are not possible, review the controller and personal computer settings.

- When all the bits of the controller IP address that correspond to 0 part of the personal computer subnet mask are on or off:

Ex.

Controller IP address: 64.64.255.255

IP address for the personal computer: 64.64.1.1

Subnet mask for the personal computer: 255.255.0.0

- When all the bits of the controller IP address that correspond to the host address of each class of the personal computer IP address are on or off:

Ex.

IP address for the personal computer: 192.168.0.1 ← 192.x.x.x., class C and the host address is the fourth octet.

Subnet mask for the personal computer: 255.0.0.0

IP address for the controller: 64.255.255.255 ← Each bit turns on because the fourth octet is 255.

Point

The IP address for each class are as follows.

- Class A: 0.x.x.x to 127.x.x.x
- Class B: 128.x.x.x to 191.x.x.x
- Class C: 192.x.x.x to 223.x.x.x

The host address for each class is the 0 section shown below.

- Class A: 255.0.0.0
- Class B: 255.255.0.0
- Class C: 255.255.255.0

Specifying IP address

It is used to connect to an Ethernet-equipped module that has no network number and station number settings or no settings, or to connect multiple MELSOFT products.

The availability of unencrypted/encrypted communications with MELSOFT products and GOT are shown below.

○: Available, ×: Not available

Connection device*1	Whether unencrypted communications are available		Whether encrypted communications are available	
	Port for CC-Link IE TSN	Port for Ethernet	Port for CC-Link IE TSN	Port for Ethernet
MELSOFT products	×	○	×	○
GOT	×	○	×	×

*1 For the port allocation, refer to the following.
☞ Page 50 MX-R Model

Precautions

When UDP or DTLS is used as the communication protocol, problems such as loss of data and data arrival order interchange may occur. If such a problem occurs, consider using the TCP or TLS protocol.

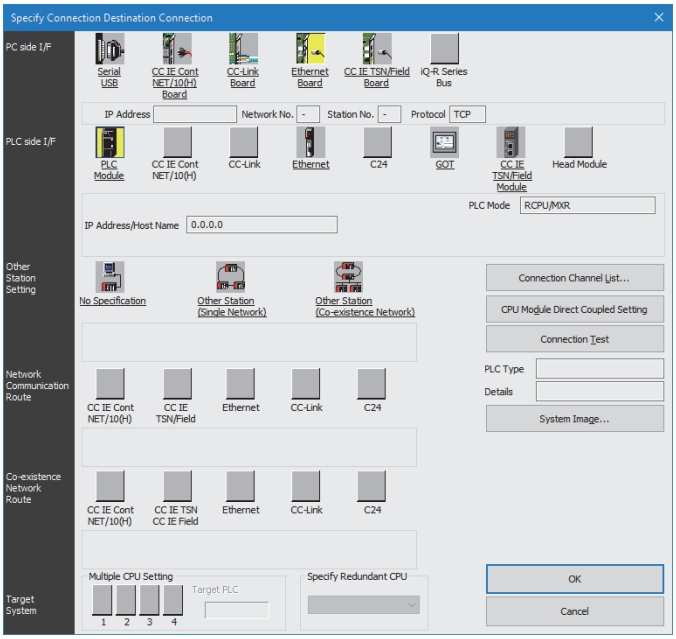
Ethernet port setting method

■Controller settings

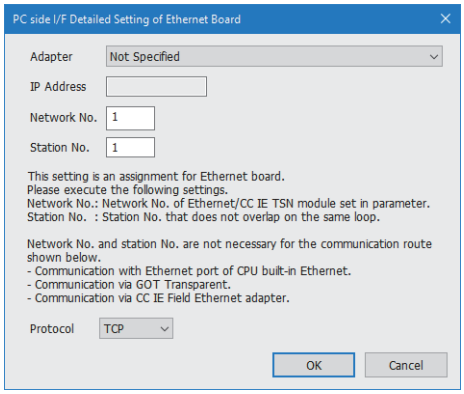
Set the IP address of the controller in "Required Settings" in "Module Parameter (Ethernet)".

The controller can be connected to MELSOFT products and GOTs using the system dedicated connection without setting in "External Device Configuration" of "Basic Settings" under "Module Parameter (Ethernet)".*1

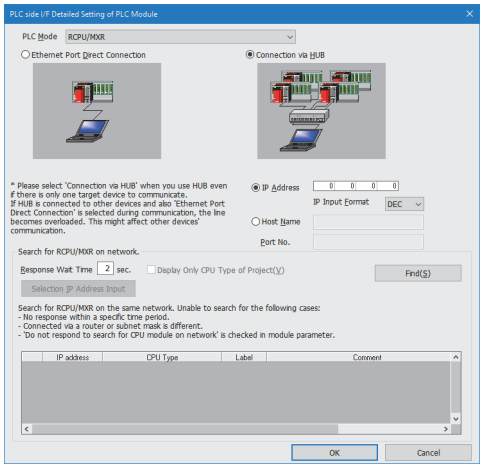
*1 When using a TCP/IP connection with the system dedicated connection, up to ((maximum number of connected modules in "External Device Configuration") - (set number) + 1) modules can be connected.
When using a UDP/IP connection, up to the maximum number of connectable modules can be connected.



Point



When connecting multiple MELSOFT products with TCP/IP, drag "MELSOFT Connection Module" from the "Module List" in "External Device Configuration" under "Basic Settings" of "Module Parameter (Ethernet)".
(☞ Page 194 "Ethernet Configuration" Window (External Device Configuration Setting))



■Settings on the engineering tool side

Set in the "Specify Connection Destination Connection" window.

[Online] ⇨ [Current Connection Destination]

1. Select "Ethernet Board" for "PC side I/F".
2. Double-click "Ethernet Board" to display the "PC side I/F Detailed Setting of Ethernet Board" window.
3. Set the adapter and protocol of the personal computer. Set the protocol according to the settings for the controller.

4. Set "PLC side I/F" to "PLC Module".
5. Double-click "PLC Module" to display the detailed setting window.
6. Select "Connection via HUB" for the connection method, and enter the IP address or host name of the controller.

7. Set "Other Station Setting" to "No Specification".

Searching modules on the network

For a connection using an industrial switch, a list of the following modules that can be searched for will appear by clicking the [Find] button on the detailed setting window.

- The controller connected to the same industrial switch as the engineering tool
- The controller connected to a cascade-connected industrial switch

Restriction

Not available for the CC-Link IE TSN port.

When module does not appear after search

If the connected controller does not appear in the list after searching the modules on the network, check the following items.

- Search cannot be performed if it is disabled with the IP filter.
- Modules connected via a router cannot be searched.
- If the module is connected via a wireless LAN, packet loss can prevent the Ethernet communications from stabilizing, and may inhibit the module search.
- If there are modules with the same IP address in the list, review the IP address parameter settings for the controller.
- If the service processing load of the search-target CPU module is high, it may not be possible to search for the corresponding module. If the search cannot be performed, increase the response wait time in the search dialog, and perform the search again.

PART 6 SPECIFICATIONS

This part consists of the following chapters.

11 GENERAL SPECIFICATIONS

12 PERFORMANCE SPECIFICATIONS

11 GENERAL SPECIFICATIONS

This chapter describes general specifications such as the usage environment.

Item	Specifications					
Operating ambient temperature	0 to 55℃					
Storage ambient temperature	-25 to 75℃					
Operating ambient humidity	5 to 95%RH, non-condensing					
Storage ambient humidity	5 to 95%RH, non-condensing					
Vibration resistance	—	Frequency	Constant acceleration	Half amplitude	Sweep count	IEC 61131-2: 2007/JIS B 3502: 2011
	Under intermittent vibration	5 to 8.4Hz	—	3.5mm	10 times each in X, Y, and Z directions	
		8.4 to 150Hz	9.8m/s²	—		
	Under continuous vibration	5 to 8.4Hz	—	1.75mm	—	
		8.4 to 150Hz	4.9m/s²	—		
Shock resistance	Three shocks in each direction per axis, on 3 mutually perpendicular axes (total of 18 shocks)					
Operating atmosphere	No corrosive gases*4 and flammable gases, less conductive dust					
Operating altitude*1	0 to 2000m					
Installation location	Inside a control panel intended for indoor use					
Overvoltage category*2	Ⅱ or less					
Pollution degree*3	2 or less					

*1 Do not use or store the controller under pressure higher than the atmospheric pressure of altitude 0m. Doing so may cause malfunction.

*2 This indicates the section of the power supply to which the equipment is assumed to be connected between the public electrical power distribution network and the machinery within premises. Category Ⅱ applies to equipment for which electrical power is supplied from fixed facilities. The surge voltage withstand level for up to the rated voltage of 300V is 2500V.

*3 This index indicates the degree to which conductive material is generated in terms of the environment in which the equipment is used. Pollution degree 2 is when only non-conductive pollution occurs. A temporary conductivity caused by condensing must be expected occasionally.

*4 When using the controller in the environment with the corrosive gases, use the special coated products having improved resistance to the environment of a certain degree of corrosive gas concentration specified in IEC 60721-3-3: 1994 3C2. For details on the special coated products, please contact your local Mitsubishi representative.

MEMO

12 PERFORMANCE SPECIFICATIONS

12.1 Controller

This section describes the specifications of the MX-R models.

Hardware specifications

Item			MXR300-16 MXR300-32 MXR300-64	MXR500-128 MXR500-256
Operation control method			Stored program cyclic operation	
I/O control mode			Refresh mode (The direct access input/output is available by specifying the direct access input/output (DX, DY).)	
Processing speed	Instruction processing time	LD instruction	0.38ns minimum	0.28ns minimum
Memory capacity	Program memory		100M bytes	150M bytes
	Program cache memory		40M bytes	80M bytes
	SD memory card*1		The capacity differs depending on the SD memory card used. (SD/SDHC memory card)	
	Device/label memory		131072K bytes	262144K bytes
	Signal flow memory		512K bytes (fixed)	
	Data memory		30M bytes	60M bytes
	Function memory		172032K bytes	
	Buffer memory		36864K bytes (18432K words)	
	Refresh memory		8M bytes	
	Motion data memory		512K bytes	1024K bytes
Number of storable files	Program memory		Number of program files: 252 Number of FB files: 128	Number of program files: 380 Number of FB files: 192
	SD memory card*2		Number of files that can be stored in the root directory of the SD memory card/Number of files that can be stored in the subdirectory of the SD memory card • 2GB: 511/65534 • 4GB, 8GB, 16GB: 65535/65534	
	Device/label memory		324	
	Data memory*3		7616	15244
	Function memory*3		LOGGING: 10172, motion: 8129, other: 8129 (☞ Page 322 Function memory)	
	Motion data memory		512	1024
USB port			USB2.0 High Speed (Type-C) × 1	
Ethernet port	Number of ports		3	
	Interface		RJ45 connector (Auto MDI/MDI-X)	
Clock function	Display		Year, month, date, hour, minute, second, and day of the week (automatic leap year adjustment)	
	Accuracy		-1.00 to +1.00s/d at 0 to 55℃	
Number of occupied I/O points			64 points (CC-Link IE TSN function part: 32 points, motion function part: 32 points)	
Backup power	Backup method		Capacitor	
	Backup power time		10 days (under an ambient temperature of 25℃)	
	Data retained		Clock data	
Allowable momentary power failure time			The time differs depending on the power supply module used. (📖MELSEC iQ-R Module Configuration Manual)	
Internal current consumption (5VDC)			2.83A	3.22A
External dimensions	Height		110mm (base unit mounting side: 98mm)	
	Width		84.2mm	
	Depth		131mm	
Weight			0.72kg	

*1 The memory capacity of an SD memory card used for the system may be additionally consumed by the file operation processing speed enhancement. (The consumed capacity varies depending on the usage environment.)
To free up the consumed capacity, turn on the controller power while the SD memory card is inserted, or eject and insert the SD memory card.

*2 If the number of characters in a file name is 12 characters or less (including single-byte alphanumeric characters and the extension), the total number of files and folders shown in the above table can be stored in the root directory and each subdirectory. If a file name exceeds 12 characters or one includes lower-case characters, the number of files that can actually be stored may be reduced compared to the values shown in the above table.
When the temporary file creation setting at file transfer is set to 0: Create by the GP.FTPCGET and SP.FTPGET instructions, the extension .TMP (4 characters) is automatically provided for the file name of the temporary file to be created. Therefore, if a file name exceeding 8 characters (including the extension) is specified, the maximum number of the files that can actually be stored may be reduced.

*3 This is a total number of files and folders that can be stored in the root directory when the number of characters in a file name is 9 (including the extension). Note that the number of files that can actually be stored may increase or decrease depending on the usage status.

Programming specifications

Item			MXR300-16 MXR300-32 MXR300-64	MXR500-128 MXR500-256
Programming language			• Ladder diagram (LD) • Structured text (ST) • Function block diagram (FBD/LD)	
Programming supporting function			• Function block (FB) • Label programming	
Program operation	Execution type		• Initial execution type • Scan execution type • Fixed scan execution type • Event execution type • Standby type	
	Type of interrupt		• Interrupt using the internal timer (I28 to I31) • High-speed internal timer interrupt 1 (I49) • High-speed internal timer interrupt 2 (I48) • Network communication cycle synchronous interrupt • Interrupt by a module	
Number of executable programs			252	380
Number of FB files			128	192
Tact performance	Constant scan		0.2 to 2000ms (The value can be set in increments of 0.1ms.)	
	Fixed scan interrupt	Interrupt using the internal timer (I28 to I31)	0.5 to 1000ms (The value can be set in increments of 0.5ms.)	
		High-speed internal timer interrupt 1 (I49)	0.05 to 1000ms (The value can be set in increments of 0.05ms.)	
		High-speed internal timer interrupt 2 (I48)	0.05 to 1000ms (The value can be set in increments of 0.05ms.)	
Timer performance	Low-speed timer		1 to 10000ms (Default: 100ms)	
	High-speed timer		0.01 to 100ms (Default: 10ms)	
	Long timer		0.001 to 1000ms (Default: 0.001ms)	
Number of I/O points			4K points (4096 points)*3	
Number of user device points (default)	Input (X)		12K points (12288 points (fixed))*4	
	Output (Y)		12K points (12288 points (fixed))*4	
	Internal relay (M)		64K points (65536 points)*1	
	Latch relay (L)		8K points (8192 points)*1	
	Link relay (B)		32K points (32768 points)*1	
	Link special relay (SB)		2K points (2048 points)*1	
	Annunciator (F)		2K points (2048 points)*1	
	Edge relay (V)		2K points (2048 points)*1	
	Timer device	Timer (T)	1K points (1024 points)*1	
		Long timer (LT)	4K points (4096 points)*1	
	Retentive timer device	Retentive timer (ST)	0 points*1	
		Long retentive timer (LST)	0 points*1	
	Counter device	Counter (C)	512 points*1	
		Long counter (LC)	512 points*1	
	Data register (D)		64K points (65536 points)*1	
	Link register (W)		32K points (32768 points)*1	
	Link special register (SW)		2K points (2048 points)*1	
Number of system device points	Special relay (SM)		4496 points (fixed)	
	Special register (SD)		4496 points (fixed)	
	Function input (FX)		16 points (fixed)	
	Function output (FY)		16 points (fixed)	
	Function register (FD)		5 points × 4 words (fixed)	
Number of file register points (default)	File register (R/ZR)		0 points*1	

Item		MXR300-16 MXR300-32 MXR300-64	MXR500-128 MXR500-256
Number of index register points (default)	Index register (Z)	24 points (fixed)	
	Long index register (LZ)	12 points (fixed)	
Number of pointer points	Pointer (P)	8192 points (16384 points maximum)*1	16384 points (32768 points maximum)*1
	Interrupt pointer (I)	1024 points (fixed)	
Number of link direct device points*2	Link input (J□\X□)	160K points maximum	
	Link output (J□\Y□)	160K points maximum	
	Link relay (J□\B□)	640K points maximum	
	Link register (J□\W□)	2560K points maximum	
	Link special relay (J□\SB□)	5120 points maximum	
	Link special register (J□\SW□)	5120 points maximum	
Number of module access device points	Intelligent function module device (U□\G□)	268435456 points maximum	
Number of CPU buffer memory access device points	Buffer memory (U3E□\G□)	512K points maximum (Up to 268435456 points can be input by using the engineering tool.)	
Number of refresh data register points (default)	Refresh data register (RD)	1024K points (4096K points maximum)	
Number of nesting points	Nesting (N)	15 points	

*1 The points can be changed by using the parameter. For the setting range, refer to the following.
☞ Page 347 Device Setting

*2 These are the maximum points that can be handled in the controller. The number of points actually used differs depending on the module (network) used.
X: 16K points, Y: 16K points, B: 32K points, W: 16K points, SB: 4K points, SW: 4K points when CC-Link IE TSN is used
X: 8K points, Y: 8K points, B: 32K points, W: 128K points, SB: 512 points, SW: 512 points when CC-Link IE Controller Network is used

*3 When a module such as an I/O module and intelligent function module is mounted, allocate I/O points based on the number of I/O points of each module as set in the I/O assignment. (X/Y0 to FFF) (☞ Page 133 I/O Numbers of Modules)

*4 The number of points that can be used in the program.

Motion control specifications

This section describes the performance specifications of motion control.

Item			MXR300-16 MXR300-32 MXR300-64	MXR500-128 MXR500-256
Number of controlled axes	Real drive axis		MXR300-16: 16 axes MXR300-32: 32 axes MXR300-64: 64 axes	MXR500-128: 128 axes MXR500-256: 256 axes
	Real drive axis + the other axes		10000 axes maximum The number of axes that can be set varies depending on the system memory capacity setting. (Depends on the amount of system memory that is set.)	
Operation cycle			1000.00μs: 64 axes	500.00μs: 64 axes
Operation cycles mixed			3 groups	
Control unit system			Double-precision real number (LREAL type), any unit string	
System memory size			256MB	
Size of built-in ROM for user data			30MB (Data memory is used.)	60MB (Data memory is used.)
Number of connectable motion control FBs			256	
Electronic cam	Number of registrations		60000 maximum	
	Cam data	Zone division, spline interpolation (resolution)	8 to 65535	
		Linear interpolation (coordinate number)	2 to 65535	
	Area sizes available		Parameter setting (The sizes depend on the amount of system memory that is set.)	

Network specifications

This section describes the network specifications.

Performance specifications of CC-Link IE TSN

The following table lists the performance specifications of CC-Link IE TSN.

Item			MXR300-16 MXR300-32 MXR300-64	MXR500-128 MXR500-256
Maximum number of link points per network[*1]		RX/RY	16K points (16384 points, 2K bytes) for each	
		RWr/RWw	8K points (8192 points, 16K bytes) for each	
Maximum number of link points per station	Master station	RX/RY	16K points (16384 points, 2K bytes) for each	
		RWr/RWw	8K points (8192 points, 16K bytes) for each	
Transient transmission capacity			1920 bytes maximum (259 bytes maximum for the send data size)	
Communication speed			• 1Gbps • 100Mbps	
Minimum synchronization cycle			125.00μs	
CC-Link IE TSN Class			CC-Link IE TSN Class B device	
CC-Link IE TSN Protocol version			2.0/1.0	
Maximum number of connectable stations per network			254 stations (master station: 1, device stations: 253[*2*3])	
Communication cable			☞ Page 62 Ethernet cable	
Overall cable distance		Line topology	25300m (when 254 stations are connected)	
		Others	Depends on the system configuration.	
Maximum station-to-station distance			100m	
Maximum number of networks			239	
Network topology			Line topology, star topology, coexistence of line and star topologies	
Communication method			Time sharing method	
Multicast filter			Not available	
Number of extension modules per main module			7	

*1 All link devices may not be able to use its maximum number of points simultaneously depending on the number of device stations, or the number of points and assignments of the link devices that are set in "Network Configuration Settings" of "Basic Settings".

*2 The maximum number of connectable stations becomes 256 when modules that operate as extension modules, such as a multiple-axes drive unit, are included in the number.

*3 Depending on the device station used, the number of connectable stations varies on the trunk line of one port of the master station. Refer to the manual for the device station to check the maximum number of connectable stations. Then, ensure that the maximum number of connectable stations is not exceeded for each device station on the trunk line of one port of the master station.
Also, when using 121 or more device stations, check the following.
· For information on the device stations manufactured by Mitsubishi Electric, refer to the Line Topology with 121 or More Device Stations (CC-Link IE TSN Products) (FA-A-0451).
· Device stations not manufactured by Mitsubishi Electric are considered incompatible with line topology with 121 or more stations.

Performance specifications of Ethernet

The following table lists the performance specifications of Ethernet.

Item			MXR300-16 MXR300-32 MXR300-64	MXR500-128 MXR500-256
Transmission specifications	Data transmission speed		• 1Gbps • 100Mbps	
	Communication mode	100BASE-TX	Full-duplex/half-duplex	
	Transmission method		Base band	
	Maximum frame size		1518 bytes	
	Jumbo frame		Not available	
	Maximum distance between an industrial switch and a node		100m (For the distance between industrial switches, consult the manufacturer of the industrial switches used.)	
	IP version		Compatible with IPv4	
	Maximum nodes connection	100BASE-TX	Cascade connection, 2 levels maximum	
Sending/receiving data storage memory	Number of simultaneous open connections (maximum number of connections)		■Port for Ethernet 64 connections	
	Socket communications		5K words × 64	
Number of connections	TCP		■Port for Ethernet • Total of MELSOFT connections, SLMP, and socket communications ≤ 64 connections • FTP: 1 connection	
	UDP			
	TLS			
	DTLS			

Point

The operation of commercial devices used for the following applications is not guaranteed. Check the operation before using the controller.

- Internet (general public line) (Internet-access service offered by an Internet service provider or a telecommunications carrier)
- Firewall device(s)
- Broadband router(s)
- Wireless LAN

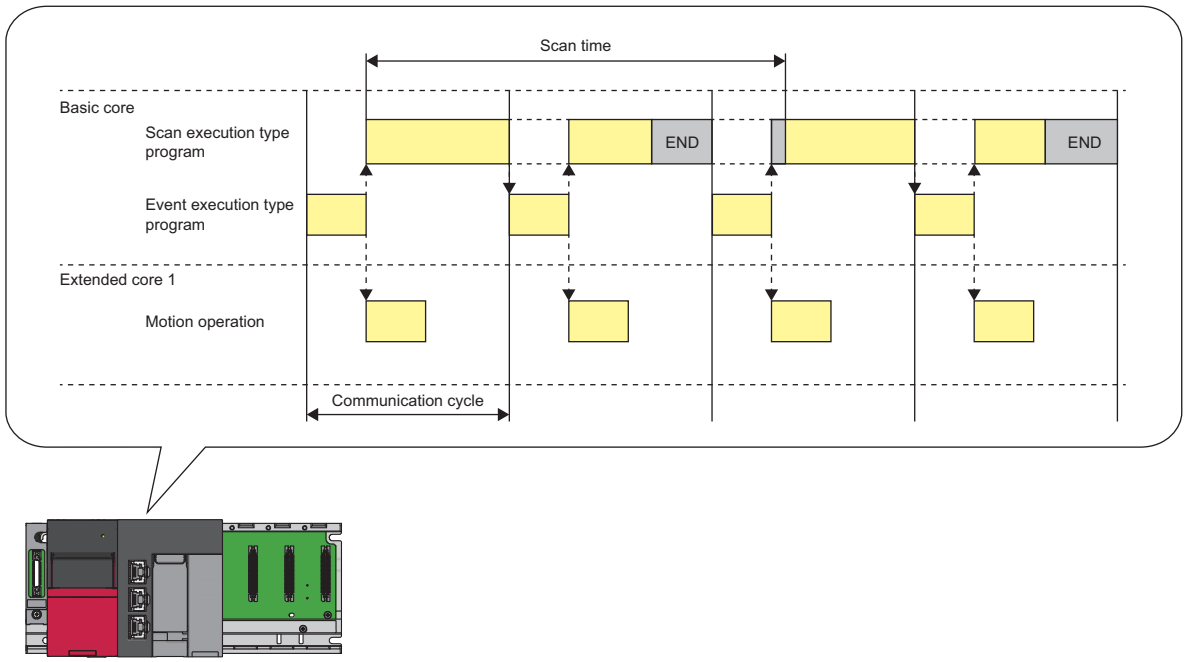
PART 7 CONTROLLER OPERATION

This part consists of the following chapters.

13 SCAN CONFIGURATION

14 RUNNING A PROGRAM

15 OPERATING STATUS OF THE CONTROLLER

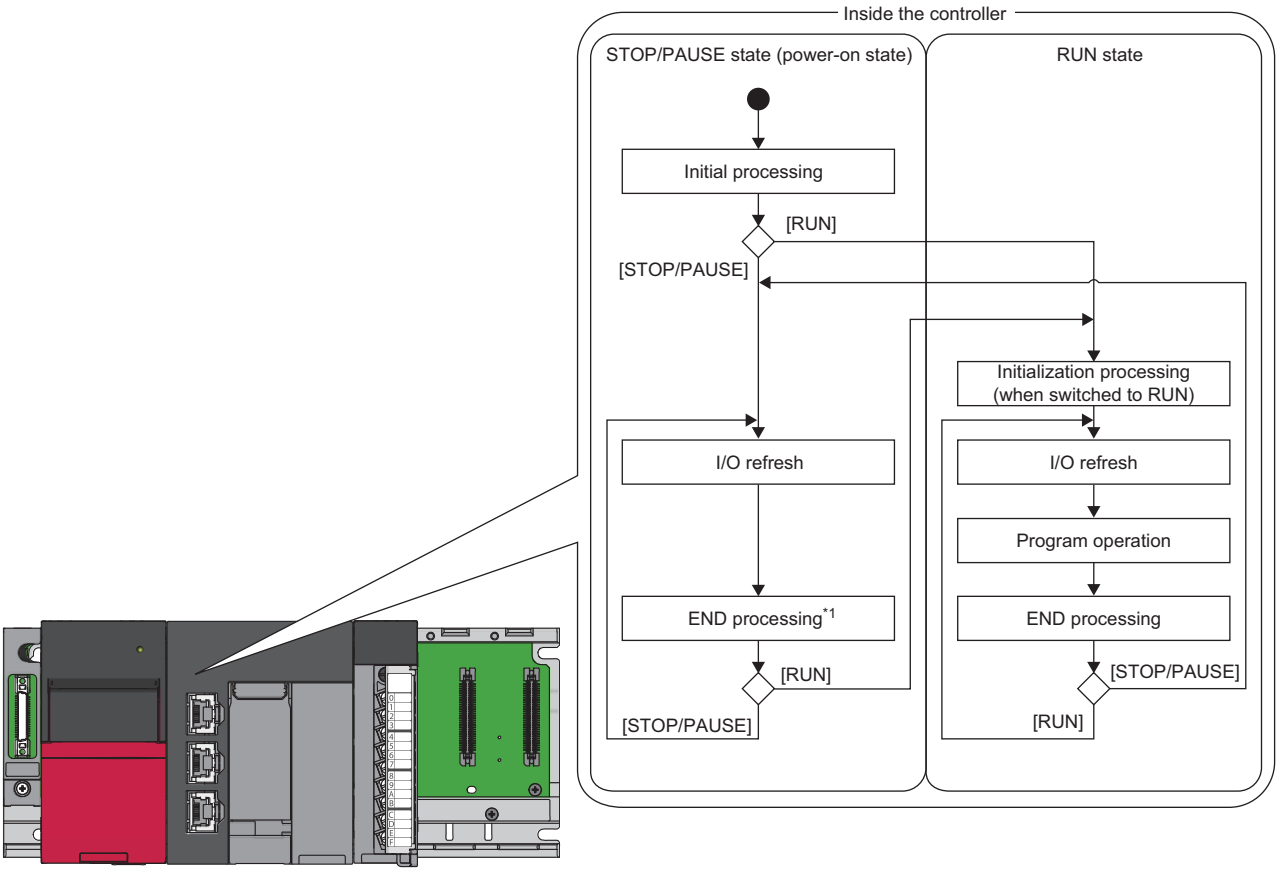


16 CC-Link IE TSN COMMUNICATION CYCLE AND MOTION OPERATION

17 CONTROLLER MEMORY CONFIGURATION

13 SCAN CONFIGURATION

The controller has multiple cores to execute programs or perform motion operation.
Multiple cores can perform operation simultaneously. For instance, the basic core executes programs and the extended core performs motion operation simultaneously.



Ex.

Point

For the program execution type, refer to the following.
☞ Page 246 Program Execution Type
For the execution of a program synchronized with the communication cycle of CC-Link IE TSN/motion operation, refer to the following.
☞ Page 284 CC-Link IE TSN COMMUNICATION CYCLE AND MOTION OPERATION

The following shows the scan configuration of the controller.

*1 The END processing differs between STOP and PAUSE.

13.1 Initial Processing (When Powered On or Switched to RUN)

For the initial processing (when powered on or switched to RUN), the following processes are performed:

Item	Initial processing	Initial processing (when switched to RUN)
Booting from an SD memory card	Executed	Not executed
Checking each parameter and program*1	Executed	Executed
Assigning the I/O number to the mounted module	Executed	Not executed
Initializing and setting the information of each module	Executed	Not executed
Restoring latch data after initializing a device/label (Bit device: Off, Others: 0)	Executed	Not executed
Setting the device/label initial value	Executed	Executed*2

*1 In the following cases, the initial processing may take time, and it may take time to respond to peripherals.
· The SD memory card has too many files, or the SD memory card is close to the end of life or it has reached the end of life.
· It takes time to check each parameter and program depending on the parameter settings and the number of programs.

*2 The operation may vary depending on the parameter settings. For details, refer to the following.
☞ Page 427 Initial value setting

13.2 I/O Refresh

The module performs the following before starting program operation.

- ON/OFF data input from the input module/intelligent function module to the controller
- ON/OFF data output from the controller to the output module/intelligent function module

Point

While constant scan is in progress, I/O refresh is performed after the waiting time for constant scan expires.

13.3 Program Operation

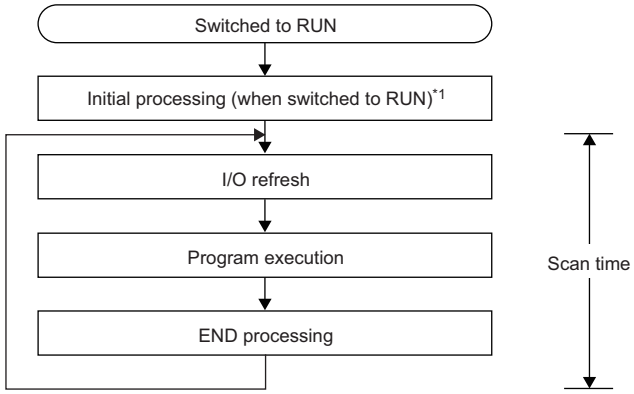
According to the program settings, the module executes from step 0 through the END/FEND instruction for each program. This program is referred to as a main routine program. A main routine program can be divided into subroutine programs. (☞ Page 260 Subroutine Program)

Point

Interrupts are enabled at power-on or reset or at transition to RUN. When an initial execution type program is registered, interrupts are disabled during the execution of the initial execution type program in the first scan after the status is changed to RUN. However, interrupts are enabled at the execution of the program in the second and subsequent scans.

13.4 END Processing

The controller performs the following processing.



- Network module link refresh
- Intelligent function module refresh
- Instruction end processing (including dedicated instruction for the module)
- Device/label latch processing
- Service processing such as read and write of devices, labels, and program access files (☞ Page 2122 Service Processing)
- Watchdog timer reset (☞ Page 1743 Watchdog timer reset)
- Data collection by the data logging function (when the collection interval is set to "Each scanning cycle" or "Sample data at the next END processing after the specified time has elapsed")
- Self-diagnostics processing
- Sets a value to the special relay/special register (for those with the set timing specified as the END processing timing)
- Sequence scan synchronization sampling function

Point

Even during the END processing, an interrupt program, fixed scan execution type program, or event execution type program (when the trigger type is set to at interrupt occurrence or network communication cycle synchronization) is executed. To prevent the execution of an interrupt program during the END processing, disable an interrupt by the DI instruction immediately before the END processing, and enable an interrupt by the EI instruction at the head of the interrupt program.

13.5 Scan Time

The controller repeats the following processing. The scan time is the sum of the following processing and execution time.

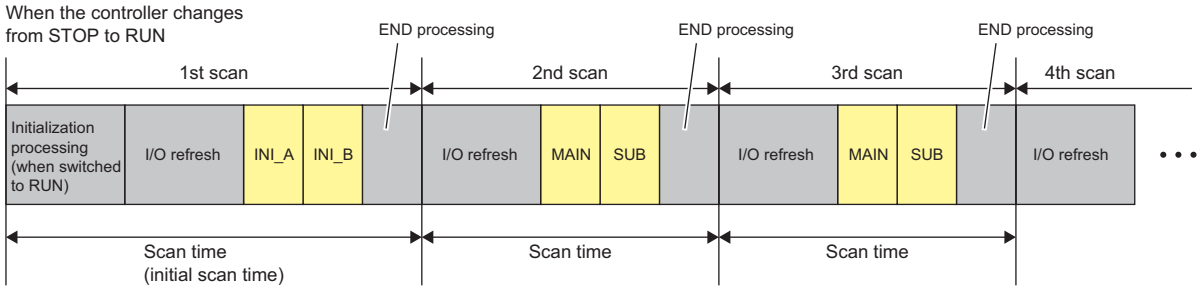
*1 The initial scan time includes this processing.

Initial scan time

The first scan time when the controller is in the RUN state

How to check the initial scan time

See below.

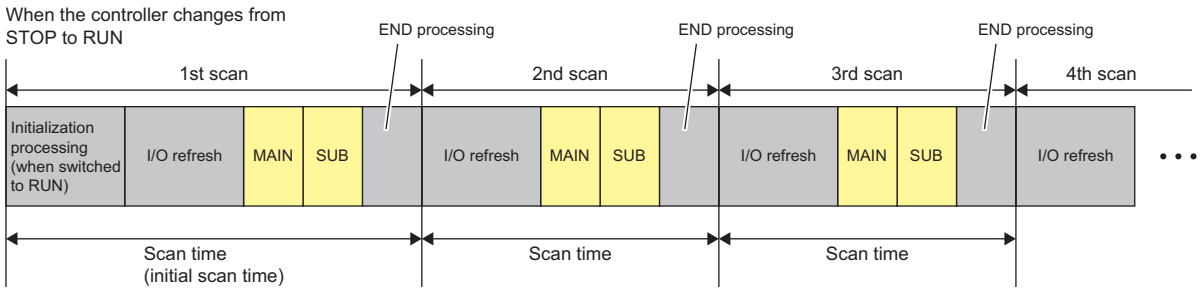


- Values stored in SD518 (Initial Scan Time) and SD519 (Initial Scan Time)

For single core execution

■When an initial execution type program exists

The following figure shows the initial scan time when there is an initial execution type program.



Program name	Execution type
INI_A	Initial
INI_B	Initial
MAIN	Scan
SUB	Scan

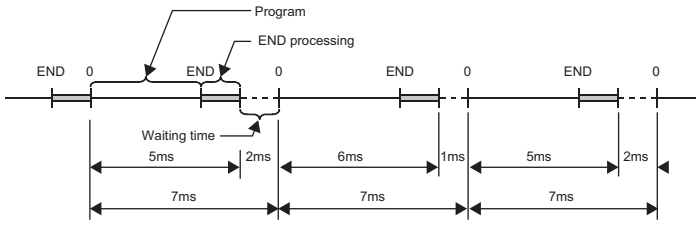
■When no initial execution type program exists

The following figure shows the initial scan time when there is no initial execution type program.

Program name	Execution type
MAIN	Scan
SUB	Scan

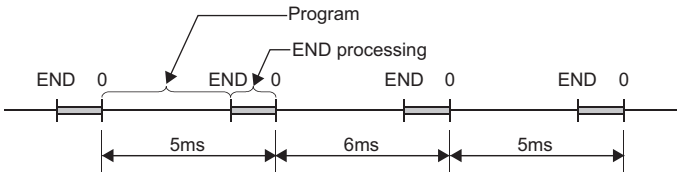
Initial scan time monitoring

Monitoring is performed with the initial scan time monitoring time. (☞ Page 1743 Scan Time Monitoring Time (WDT) Setting)



■Precautions on the initial scan time monitoring time

- Set the initial scan time monitoring time longer than the execution time of the initial scan time.

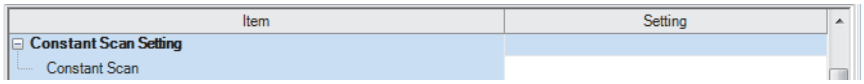


Constant scan

Scan time is different for each scan because its processing time varies depending on whether instructions used in a program are executed or not. By setting constant scan, the I/O refresh interval can be kept constant even when the program execution time varies because the program can be executed repeatedly by keeping the scan time constant.

- When constant scan is set (Setting value = 7ms)

- When constant scan is not set



Constant scan setting

Constant scan can be set.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [RAS Setting] ⇨ [Contact Scan Setting]

Window

Displayed items

Item	Description	Setting range	Default
Constant Scan	Sets the constant scan time.	0.2 to 2000ms (in increments of 0.1ms)	—

Point

The setting time for the constant scan must be a value that satisfies the relational expression below.
Watchdog timer setting time > Constant scan setting time > Maximum scan time of the program
If the execution time until constant scan wait (the time period from the start of a scan to the completion of an END processing) is longer than the constant scan setting time, a constant scan time error (error code: 1818H) is detected.

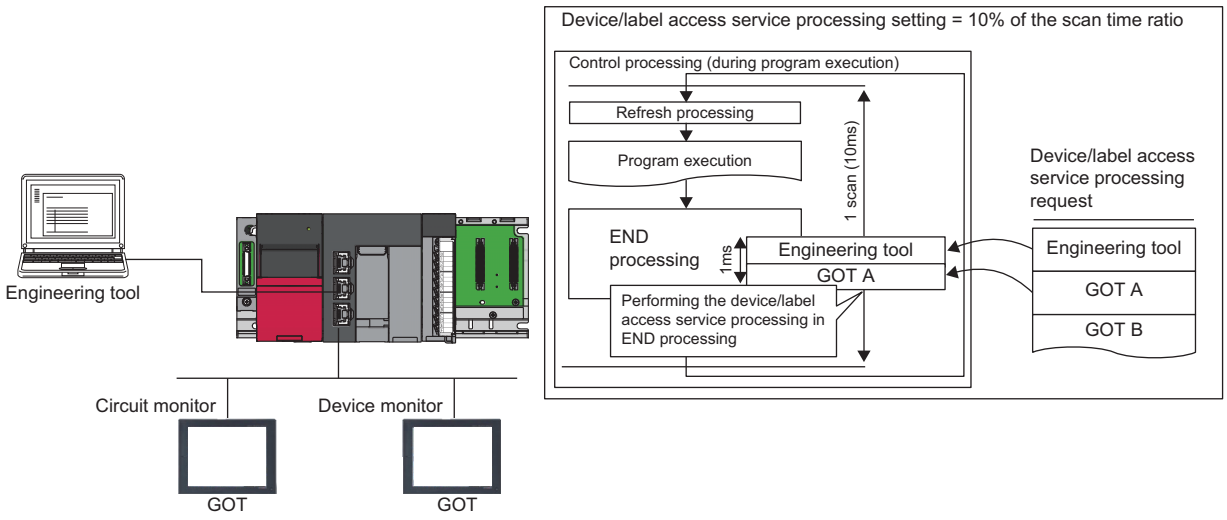
Accuracy of constant scan

The accuracy of the constant scan is 0.03ms. However, if processing, which should be executed during the waiting time from the completion of the END processing to the start of the next scan, is being executed, the constant scan cannot finish even if the constant scan time is reached. The constant scan may increase by the program execution time of the interrupt factor. (☞ Page 225 Precautions)

Precautions

Processing of the program is stopped during the waiting time from the time the END processing is completed for the program until the next scan starts. If any of the following processing requests is received during the waiting time, the corresponding processing is executed.

- Interrupt program
- Fixed scan execution type program
- Event execution type program which uses an interrupt occurrence or network communication cycle synchronization as a trigger
- Data logging function
- Realtime monitor function
- Refresh synchronized with the network communication cycle (performing only the I/O refresh processing of the synchronous station)
- Device/label access service processing
- Count processing (system interruption) after executing the special counter instruction (UDCNT1/UDCNT2)
- Label access from an add-on
- Continuation error notification at error detection by the self-diagnostic function
- Device access from an add-on whose add-on type is GI/RI



Device/label access service processing setting

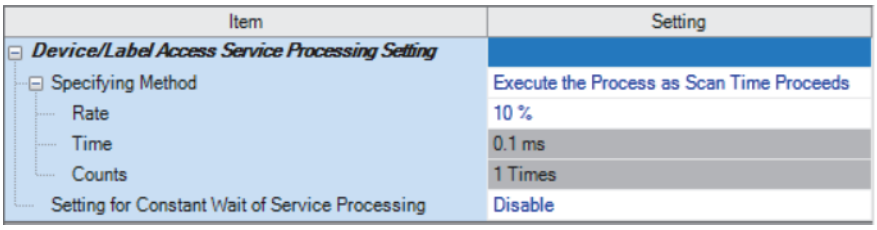
The user can specify the time or the execution timing of the device/label access service processing which is performed during the END processing.

A request to the controller from a peripheral is processed by the device/label access service processing. A communication response to a request from a peripheral varies depending on the scan time and the state of communication load. To create the service processing environment suitable for the system, change the device/label access service processing setting as shown below.

- Set a longer time for the device/label access service processing to improve a communication response to a peripheral.
- Set a shorter time for the device/label access service processing to reduce a scan time extension due to service processing.

Note that communications to the controller from multiple peripherals may lower a communication response to each peripheral. Thus, consider the performance of communication responses and the extension of scan time, and adjust the service processing environment according to the system by methods such as setting a longer time for the device/label access service processing or changing the parameter settings of peripherals so that the timeout time becomes longer.

Point



For functions to which the device/label access service processing setting can be applied, refer to the list targeted for device/label access service processing setting. (☞ Page 2122 Target list and operation details of the device/label access service processing setting)

Setting method

The device/label access service processing can be configured as follows.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Service Processing Setting] ⇨ [Device/Label Access Service Processing Setting]

Window

Displayed items

Item	Description		Setting range	Default
Specifying Method	Select a method for specifying the service processing for access to devices/labels.		• Execute the Process as Scan Time Proceeds • Set Processing Time • Set Processing Counts • Execute END Processing between Programs	Execute the Process as Scan Time Proceeds
	Rate	Set the ratio of the device/label access service processing to execute during a single scan when "Execute the Process as Scan Time Proceeds" is enabled. The device/label access service processing time is determined based on the scan time.	1 to 99% (unit: 1%)	10%
	Time	Set the device/label access service processing time per scan when "Set Processing Time" is enabled.	0.1 to 1000ms (unit: 0.1ms)	0.1ms
	Counts	Set the number of executions of the device/label access service processing per scan when "Set Processing Counts" is enabled.	1 to 10 times (unit: 1 time)	1 time
Setting for Constant Wait of Service Processing	Specify whether to enable or disable the device/label access service processing constant wait setting.		• Disable • Enable	Disable

Operations enabled by setting details

Operations enabled by setting details of the device/label access service processing setting are as follows.

Item	Scan performance		Device/label access service process performance		Inter-program monitoring *5	Application
	Increase *1	Stability *2	Response time *3	Stability *4		
Execute the Process as Scan Time Proceeds	Medium	Medium	Medium	Medium	None	This setting is useful to execute the device/label access service processing in a way commensurate with the system size. It allows the system to be designed without considering the device/label access service processing time because it is determined based on the scan time. Multiple requests are processed until the specified ratio is exceeded. If exceeded, the remaining requests are processed in the END processing of the next scan. When no request data is received in the current scan, the scan time is shortened by the specified ratio as the controller proceeds to the next scan without waiting for requests.
Set Processing Time	Medium	High	Medium	High	None	This setting is useful to give priority to the device/label access service processing. It allows for stable communication because the controller can always process a constant amount of the device/label access service processing without affecting the scan time. Multiple requests are processed until the specified processing time is exceeded. If exceeded, the remaining requests are processed in the END processing of the next scan. When no request data is received in the current scan, the scan time is shortened by the specified processing time as the controller proceeds to the next scan without waiting for requests.
Set Processing Counts	Large	Low	Medium	High	None	This setting is useful to stably execute the device/label access service processing in a system where requests come from multiple peripherals. It provides stable communication in a system where multiple peripherals exist because the controller can execute the device/label access service processing based on the number of request sources. Multiple requests are processed until the specified number of executions of the service processing is reached. When no request data is received in the current scan, the controller proceeds to the next scan without waiting for requests.
Execute END Processing between Programs	Large	Medium	Quick	High	Yes	This setting is useful to give priority to the device/label access service processing in a system with a large number of programs. It improves the communication response as it enables the device/label access service processing to be executed multiple times during a single scan. When no request data is received between program executions and/or during the END processing, the controller proceeds to the next program or scan without waiting for requests.

*1 This term indicates how long the scan time will be extended at its maximum due to the device/label access service processing.

*2 This term indicates how much the scan time will be varied due to the device/label access service processing.

*3 This term indicates how long the response time will take after a request for the device/label access service processing is received from an engineering tool or other devices.

*4 This term indicates how much the response time will be varied depending on the contents of requests for the device/label access service processing from engineering tools or other devices.

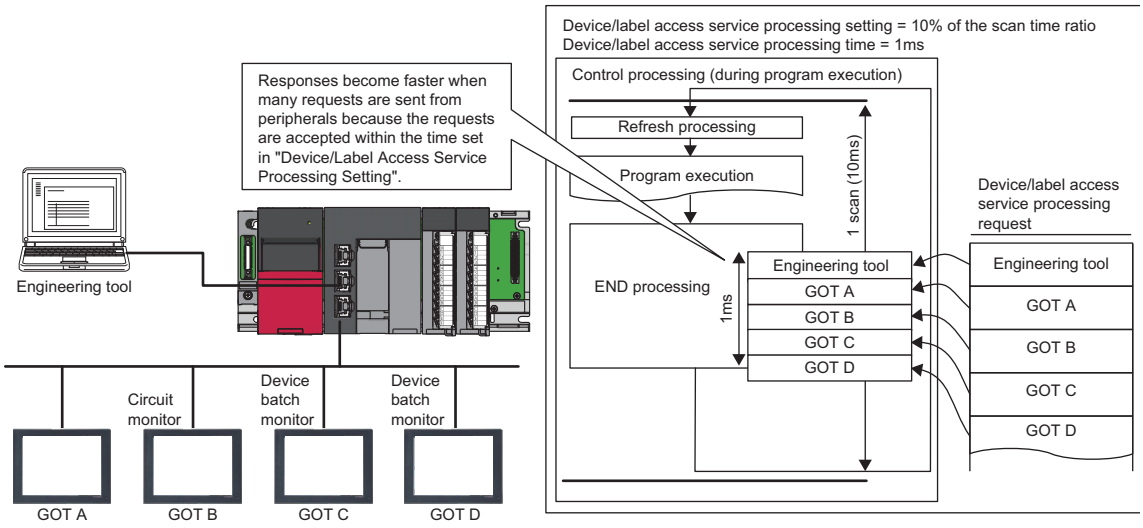
*5 When this function is enabled, monitoring is performed between execution of programs, and therefore values of ongoing operation may be read out. (☞ Page 232 When "Execute END Processing between Programs" is enabled)

For what operation is enabled by setting each item, refer to the following.

☞ Page 2124 Target list and operation details of the device/label access service processing setting

Service processing constant wait setting

This function improves the communication response of device/label access service processing requests.
By setting "Setting for Constant Wait of Service Processing" to "Enable", device/label access service processing requests are accepted until the time and ratio set in "Device/Label Access Service Processing Setting" of the CPU parameter is reached.
Even if there is no request during device/label access service processing, the function waits until the set time is reached to allow any request accepted while waiting to be processed in the same scan and its response to be returned, thereby improving the communication response for device/label access service processing requests.



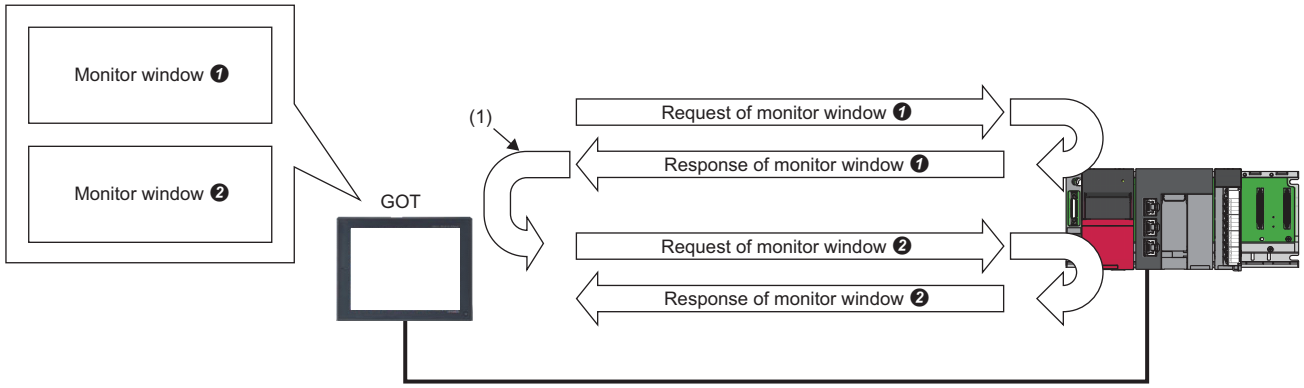
Point

• When "Setting for Constant Wait of Service Processing" is "Disable"

Requests from peripherals received up to the END processing are returned. Therefore, a scan without the device/label access service processing request move to the next scan without performing device/label access service processing, resulting in the scan time being shortened. To make the END processing time shorter than the response delay to peripherals, set "Setting for Constant Wait of Service Processing" to "Disable".
Note that when there are many requests from peripherals, the response may be delayed if the END processing time becomes longer.

• When "Setting for Constant Wait of Service Processing" is "Enable"

The response becomes faster because service processing requests are accepted until the time set in "Device/Label Access Service Processing Setting" is reached. To give priority to the response from a peripheral over the extension of the END processing, set it to "Enable". Regardless of whether there is any service processing request from a peripheral, the scan time is extended by the period of time set in "Device/Label Access Service Processing Setting". Therefore, check that the extension of the scan time does not affect control before using this function.



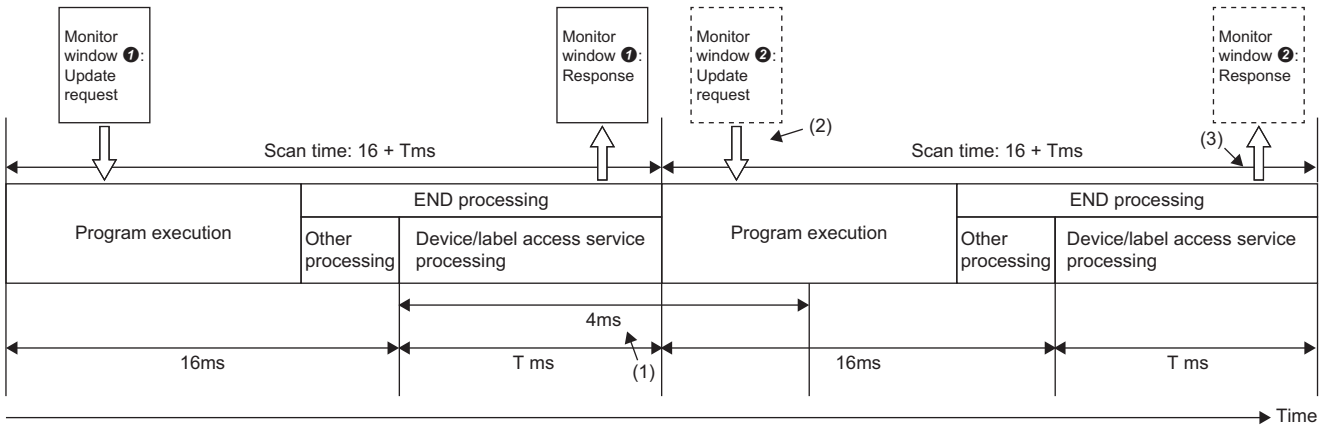
■Operation of the device/label access service processing

This section describes the operation of the device/label access service processing.

Ex.

When updating multiple monitor windows on the GOT

(1) From the time the controller sends a response until the GOT sends the next request, the controller will not receive requests from the GOT.



Depending on the GOT, when updating multiple monitor windows, the GOT repeats the action of sending a request (device/label read request) to the controller for each window and waiting for a response (a device/label current value).

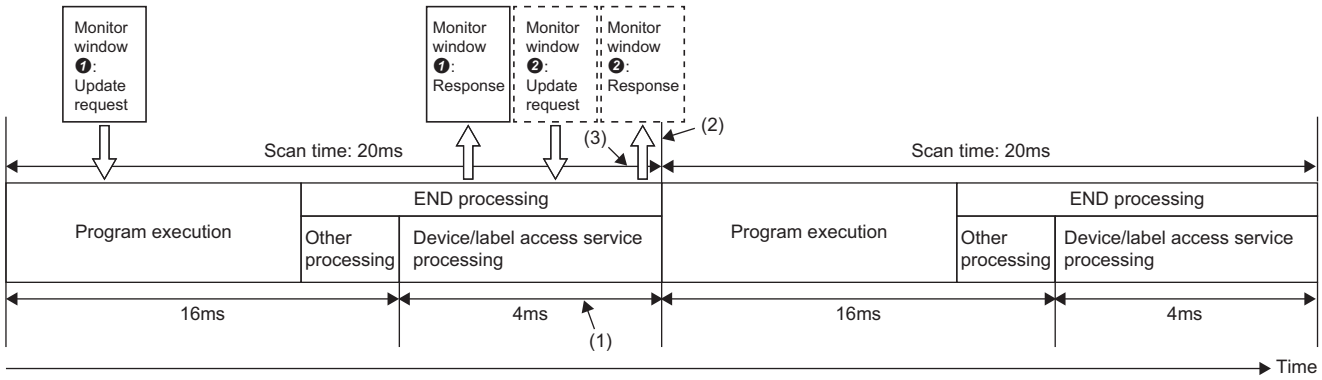
As a result, when the windows are updated in the order of monitor window ❶ → monitor window ❷, from the time the controller sends a response for monitor window ❶ until it receives a request for monitor window ❷ that follows, the controller has no request that should be processed.

When in this state, use this setting to specify whether to process a request for monitor window ❷ in the next scan or to wait until the set time is reached before processing in the same scan.

• Operation when this function is disabled

The following figure shows the operation when "Setting for Constant Wait of Service Processing" is set to "Disable". ("Device/Label Access Service Processing Setting": "Set processing time": 4ms)

(1) Since there is no request until the next request is sent from the GOT, service processing is terminated without waiting for the set time.



(2) The response is delayed due to waiting until the next device/label access service processing.

(3) One scan will process update requests from one monitor window.

After the controller returns a response to the peripheral, there is no request until the next request is sent from the peripheral. Therefore, immediately after returning the response of the monitor window ❶, the controller exits service processing and moves to the next scan without waiting for the setting time of several minutes. For this reason, even when updating multiple monitor windows, one scan can only process update requests from one monitor window. Therefore, the update interval may become longer.

• Operation when this function is enabled

The following figure shows the operation when "Setting for Constant Wait of Service Processing" is "Enable". ("Device/Label Access Service Processing Setting": "Set processing time": 4ms)

(1) Requests are accepted until the time set in "Device/Label Access Service Processing Setting" is reached.
(2) Update requests from multiple monitor windows can be processed in one scan.
(3) The communication response is improved because requests are accepted within the device/label access service processing time.

Even after the controller returns a response from the GOT, subsequent requests are accepted until the time and ratio specified in "Device/Label Access Service Processing Setting" is reached, thereby enabling update requests from multiple monitor windows to be processed in one scan. This improves the communication response.

■Operation in combination with device/label access service processing setting

When "Setting for Constant Wait of Service Processing" is "Enable", there will be constant wait for the rate or the amount of time set in "Execute the Process as Scan Time Proceeds" or "Set Processing Time" in "Device/Label Access Service Processing Setting".

If "Device/Label Access Service Processing Setting" is not set to "Execute the Process as Scan Time Proceeds" or "Set Processing Time", "Setting for Constant Wait of Service Processing" becomes "Disable" and service processing is performed in accordance with "Device/Label Access Service Processing Setting".

The following table lists the combination operation of "Device/Label Access Service Processing Setting" and "Setting for Constant Wait of Service Processing".

Device/label access service processing setting	Setting for Constant Wait of Service Processing	
	Disable	Enable
Execute the Process as Scan Time Proceeds	Exits processing without waiting for the next device/label access processing request if there is no device/label access processing request from the GOT.	Continues to wait for device/label access processing requests from the GOT for the amount of time set in "Device/Label Access Service Processing Setting".
Set Processing Time		
Set Processing Counts		Exits processing without waiting for the next device/label access processing request if there is no device/label access processing request from the GOT.
Execute END Processing between Programs		

Point

When the constant scan is set, the operation is the same as when constant scan is set, regardless of the settings of "Device/Label Access Service Processing Setting" and "Setting for Constant Wait of Service Processing". (The controller always processes one request during the END processing, and processes the remaining requests during the waiting time for the next constant scan.)

Precautions

This section describes the precautions on the device/label access service processing setting.

■Functions that may prolong the scan time

For the following functions, the scan time may become longer than the specified time during processing even when this setting is applied.

- Online change
- Realtime monitor function
- Data logging function
- Access to intelligent function modules and network modules (buffer memory read/write, diagnostic function and monitor function)
- Controller data backup/restoration function
- OPC UA server function
- Sequence scan synchronization sampling function

■When constant scan is set

The controller always processes one request during the END processing, and processes the remaining requests during the wait time for the next constant scan. Set constant scan setting time considering the time required for the device/label access service processing to execute.

If the program execution time + END processing time and the service processing to be executed exceed the constant scan setting time, Constant scan time error (error code: 1818H) will occur.

■When "Execute END Processing between Programs" is enabled

When "Execute END Processing between Programs" is enabled, the device/label access service processing, such as device access, is performed between program executions and during the END processing. Therefore, when monitoring is performed in the situation where a device value is processed across programs, values of ongoing operation may be read or written. *1

*1 Because the timing of monitoring (during execution of a program or the END processing) cannot be specified, values of ongoing operation may be read or written.

■Reading a label while writing data to the programmable controller

When a label is read while writing, including label add/change, is being performed to the programmable controller, unintended data may be read.

13.6 Data Communication and I/O Processing

Data communication

In data communication, data such as I/O signals, buffer memory, and link device of the controller and intelligent function module are communicated.

There are two modes for data communication: refresh mode which automatically sends/receives the module data into the device or label of the controller at the END processing and direct mode which accesses when an instruction is executed in a program.

When data communication is conducted for the module where a major error occurs, the following operation is performed:

- When access by the contact instruction is executed for the controlled module, non-running, rather than an error, is returned. When direct access by other instructions is executed, Module major error (error code: 2450H) occurs.
- No error occurs when direct access for the non-controlled module is executed.

I/O processing and response delay

The controller uses the refresh mode in I/O processing. Using the direct access input/output in a program, however, allows the controller to perform I/O processing in the direct mode at the time of each instruction execution. This section describes these I/O processing modes of the controller and response delays.

Refresh mode

The controller performs I/O processing collectively at a specified timing. The following table lists the refresh timing which can be specified. (☞ Page 234 Refresh mode)

Refresh timing	Description
When END processing is performed	The refresh processing is performed in every END processing*1.
At the execution time of specified program	The refresh processing is performed before and after specified program execution. (☞ Page 259 Group setting for refresh)

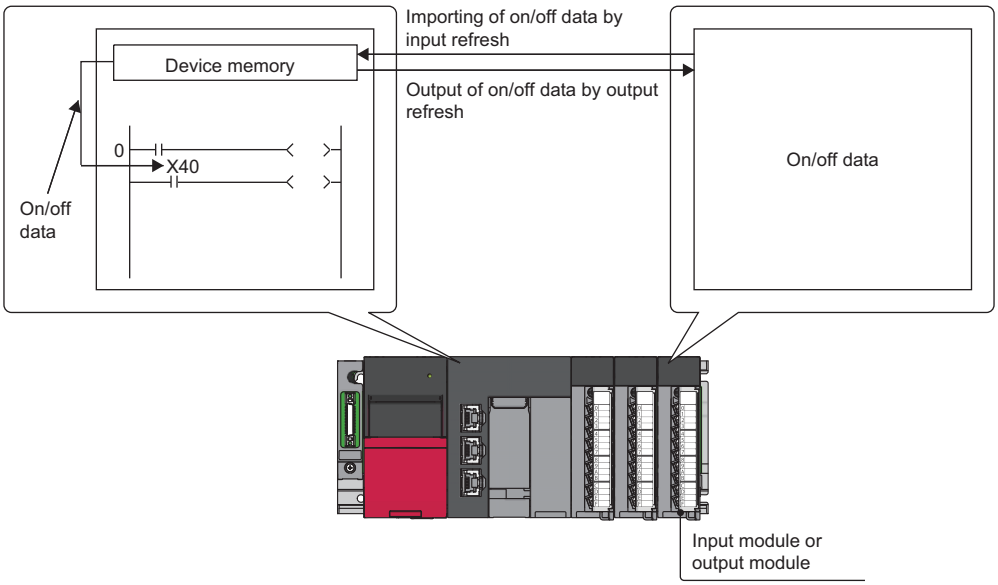
*1 There are modules which performs the refresh processing at a specified END processing rather than at every END processing. (📖 User's manual for the module used)

Direct mode

The controller performs I/O processing when each instruction is executed in a program. To access input/output modules in the direct mode, use the direct access input or direct access output in a program. (☞ Page 241 Direct mode)

Differences between refresh mode and direct mode

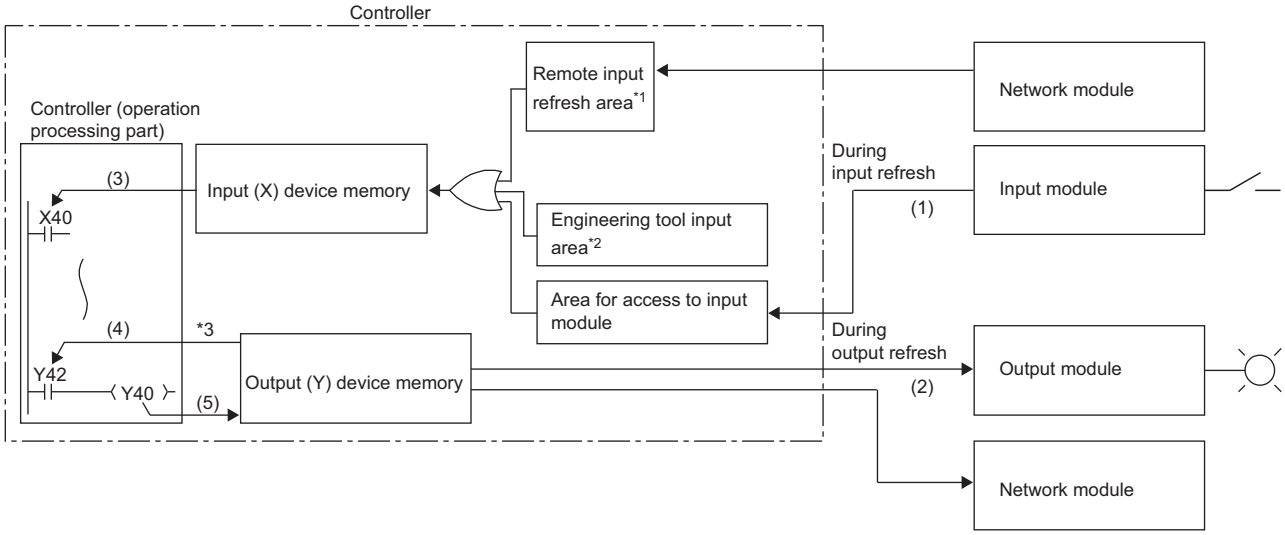
The direct mode directly accesses I/O modules at execution of an instruction. Therefore, data is input faster than when it is input in refresh mode. Processing time required for each instruction, however, takes longer. The following table lists the availability of the refresh mode and the direct mode for each input and output.



Item	Refresh mode	Direct mode
Input/output modules	Enabled	Enabled
Input/output of intelligent function modules		
Remote input/output in CC-Link IE TSN, CC-Link IE Controller Network, CC-Link IE Field Network, or CC-Link		Disabled

Refresh mode

This mode exchanges data at the specified timing (at the END instruction execution or before the specified program is executed) between the CPU function part memory (device and module labels, network labels) and each module, motion function part, CC-Link IE TSN function part input/output signal (X, Y), and internal memory (link device (RX, RY, RWr, RWw, SB, SW), buffer memory).



The controller performs I/O processing collectively at a specified timing.

The timing of the input refresh and output refresh follows the specified refresh timing setting.

Outline of the processing

The following describes the details of the refresh mode.

*1 The remote input refresh area indicates the area to be used when refresh is set to the input (X) in CC-Link IE TSN, CC-Link IE Controller Network, CC-Link IE Field Network, or CC-Link.

*2 Data in the engineering tool input area can be turned on or off by the following:
- · Test operation of an engineering tool
- · Writing data from the network module
- · Writing data from an external device using SLMP

*3 Data in the output (Y) device memory can be turned on or off by the following:
- · Test operation of an engineering tool
- · Writing data from the network module
- · Writing data from an external device using SLMP

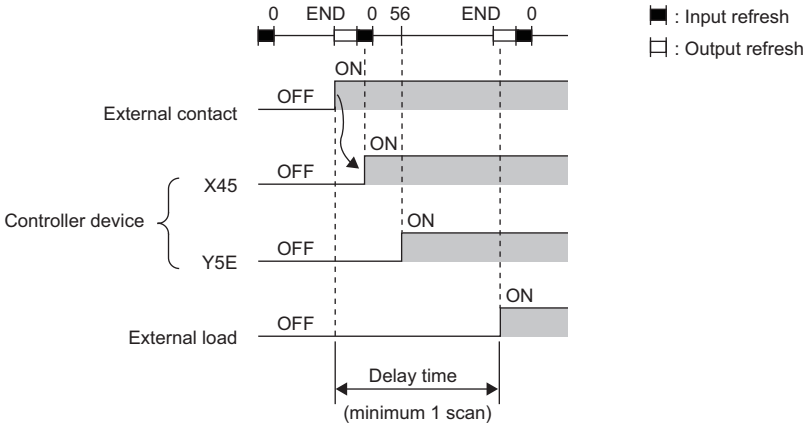
Item	Description
Input refresh	At a specified timing (at END instruction execution or before specified program execution), input data are collectively read out from the input modules (1), the OR processing with the engineering tool input area and remote input refresh area is executed, and then the data are stored in the input (X) device memory.
Output refresh	At a specified timing (at END instruction execution or before specified program execution), data in the output (Y) device memory (2) are collectively output to the output module.
Execution of an input contact instruction	Input data in the input (X) device memory (3) are read out and the program is executed.
Execution of an output contact instruction	Output data in the output (Y) device memory (4) are read out and the program is executed.
Execution of the OUT instruction	The operation result of the program (5) are stored to the output (Y) device memory.

■Input

ON/ OFF data of an input module are batch-input to the area for communication with the input module in the controller at a specified timing (at END instruction execution or before specified program execution). The controller performs program operations using the on/off data stored in the input (X) device memory.

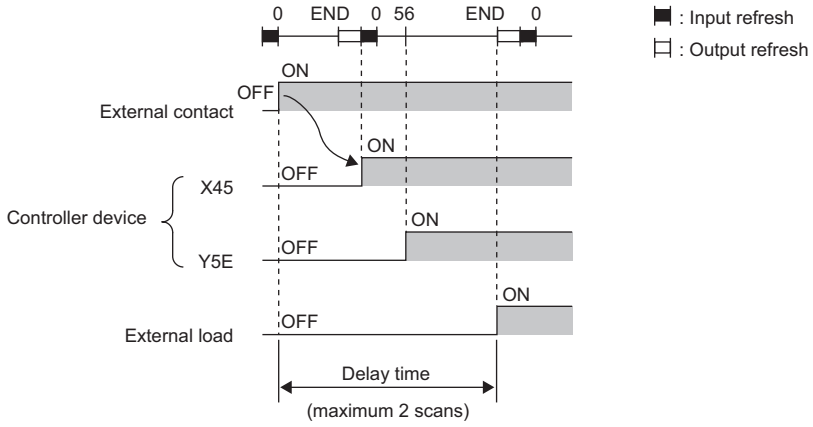
■Output

The operation result of the output (Y) program is output to the output (Y) device memory in the controller every time program operation is performed. Then, the controller batch-outputs the ON/OFF data in the output (Y) device memory to an output module at a specified timing (at END instruction execution or before specified program execution).



Response delay

An output response which corresponds to the status change in the input module delays for two scans (maximum) depending on the on timing of an external contact.



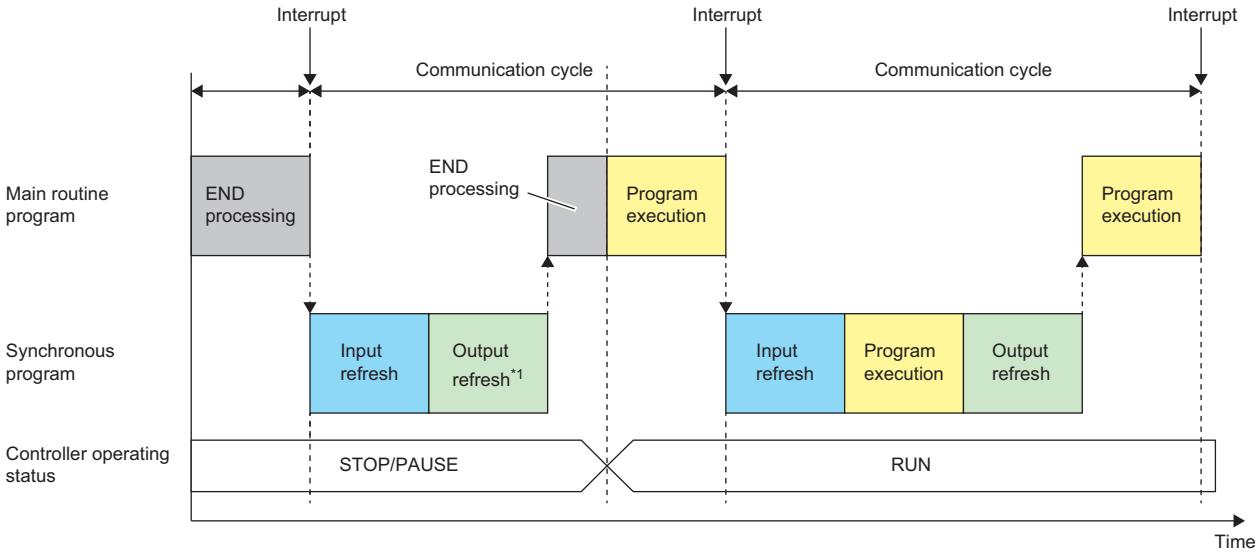
[Example] A program that turns on the output Y5E when the input X45 turns on

• Y5E turns on the earliest

• Y5E turns on the latest

Refresh synchronized with the network communication cycle

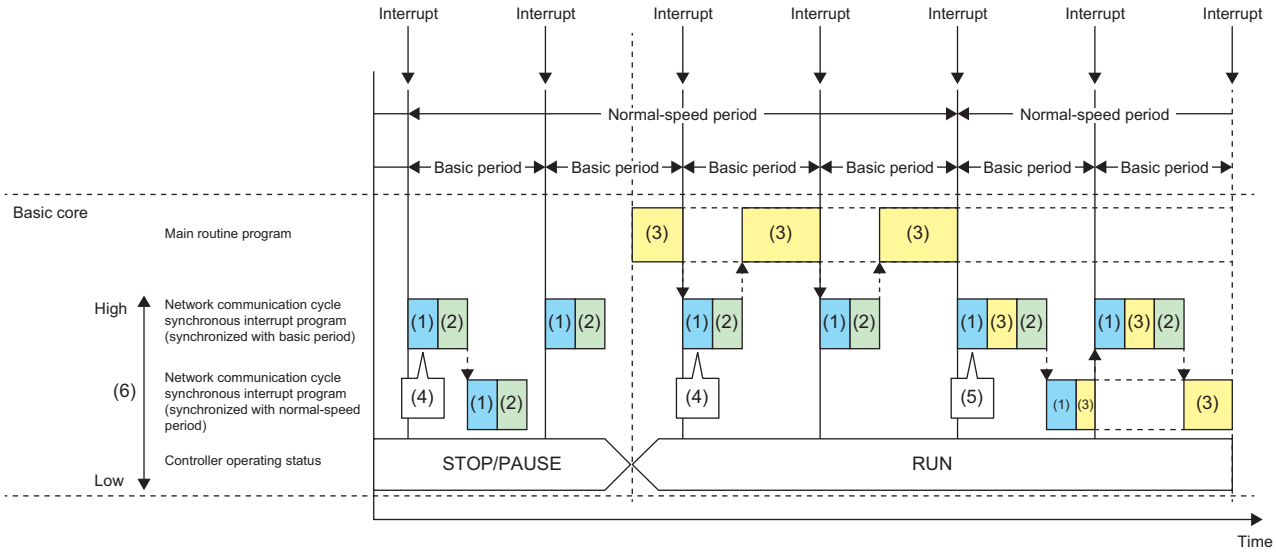
When the network synchronous communication function of the built-in network is used, refresh is performed in synchronization with the network communication cycle.



Point

For device stations that refresh in synchronization with the network communication cycle, by using [Network Configuration Settings] under [Basic Settings] of the module parameter (TSN), set [Network Synchronous Communication] to "Synchronous". Device stations set to "Asynchronous" are refreshed by the END processing.

■Operation during STOP/PAUSE



Refresh is performed when an interrupt (synchronous interrupt) occurs in the network communication cycle.
Also, if there is a program that synchronizes with the network communication cycle (event execution type program triggered by network communication cycle synchronization), refresh and program are executed when a synchronization interrupt occurs after transition to RUN.
Also, if there is an event execution type program which uses network communication cycle synchronization with different operation cycles as a trigger, only refresh is performed until the program is executed, and the program is executed in the first cycle (1st/N cycle) of the slowest cycle after transition to RUN.

• Operation during STOP/PAUSE

*1 Only refresh is performed.

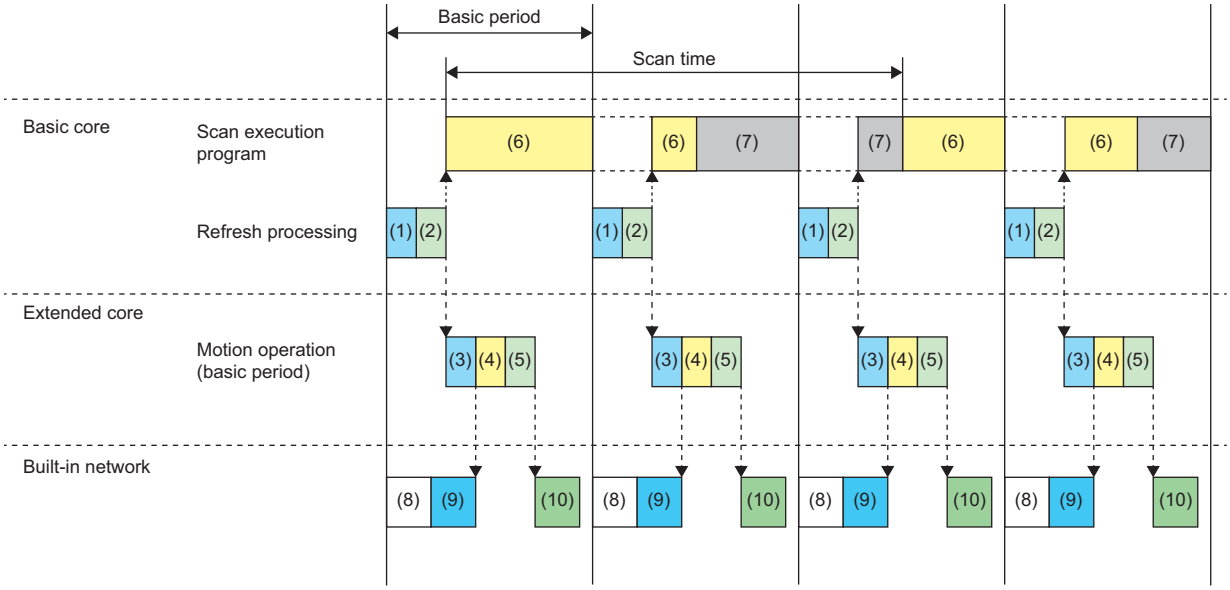
• Operation after transition to RUN when multiple cycles are mixed

(1) Input refresh
(2) Output refresh
(3) Program execution
(4) Only refresh is performed.
(5) Program is executed in the first cycle (1st/N cycle) of the slowest cycle.
(6) Interrupt priority

Point

When the controller status changes from RUN to STOP, program execution stops, but motion control decelerates and stops. Therefore, refresh processing continues when a synchronous interrupt occurs.
For information on the operation performed when an axis under motion control stops, refer to the following.
☞ Page 578 Stop

■Operation during RUN



• When an event execution type program which uses network communication cycle synchronization as a trigger is used

Refresh is performed before and after the network communication cycle synchronous interrupt program execution. Therefore, the execution core and interrupt priority for refresh processing are the same as for the synchronous program.

• When an event execution type program which uses network communication cycle synchronization as a trigger is not used

Only refresh is performed when a synchronous interrupt occurs, and motion operation processing is performed after refresh is completed. The refresh processing is executed in the basic core, and the interrupt priority follows the interrupt priority settings of the CPU parameter. (☞ Page 275 Interrupt Priority Setting)

The following figure shows the refresh operation when the synchronization program is not used.

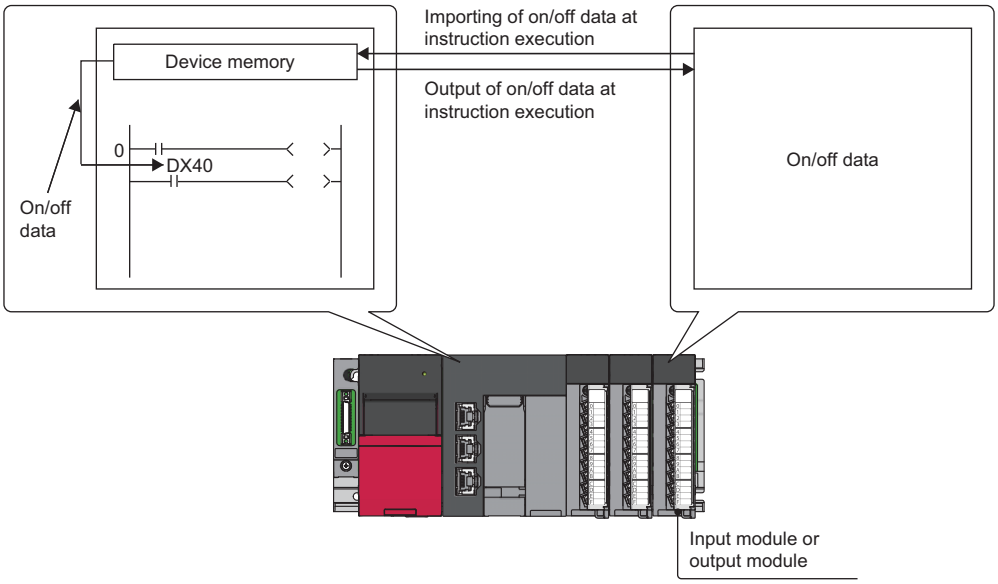
(1) Input refresh of the synchronous station (basic cycle)
(2) Output refresh of the synchronous station (basic cycle)
(3) Input processing of motion operation (basic cycle)
(4) Operation processing of motion operation (basic cycle)
(5) Output processing of motion operation (basic cycle)
(6) Execute the scan execution program.
(7) END processing (input/output refresh of the asynchronous station)
(8) Cyclic transmission
(9) Cyclic receive processing
(10)Cyclic send processing

Point

- When an event execution type program which uses network communication cycle synchronization as a trigger is not used, the interrupt priority for refresh processing follows the interrupt priority settings of the CPU parameter. Therefore, to have refresh processing run first, set the priority of other programs to low. (☞ Page 275 Interrupt Priority Setting)
- When [Network Synchronous Communication] of a device station with the medium-speed or low-speed cycle is set to "Synchronous", set [Network Synchronous Communication] of one or more device stations with the basic cycle to "Synchronous". If only device stations with the medium-speed or low-speed cycle are set to "Synchronous", an internal network error will occur.

■Checking received data using the watchdog counter

In the refresh synchronized with the communication cycle of the network, the watchdog counter sent with the received data from the device to be synchronized is used to check whether the received data is the data generated by the device to be synchronized for each communication cycle, It is checked for each device that is distinguished by the module number.
As a result of the check, if it is determined that the data generated for each communication cycle has been received, the received data is transferred to the device/label. If it is determined that the data is not generated for each communication cycle, the data received from the corresponding device will not be transferred to the device/label.
For the watchdog counter, refer to the following.
☞ Page 289 Watchdog counter
For the module number, refer to the following.
☞ Page 2060 Synchronous communication received data transfer status (Module No.1) to Synchronous communication received data transfer status (Module No.256)

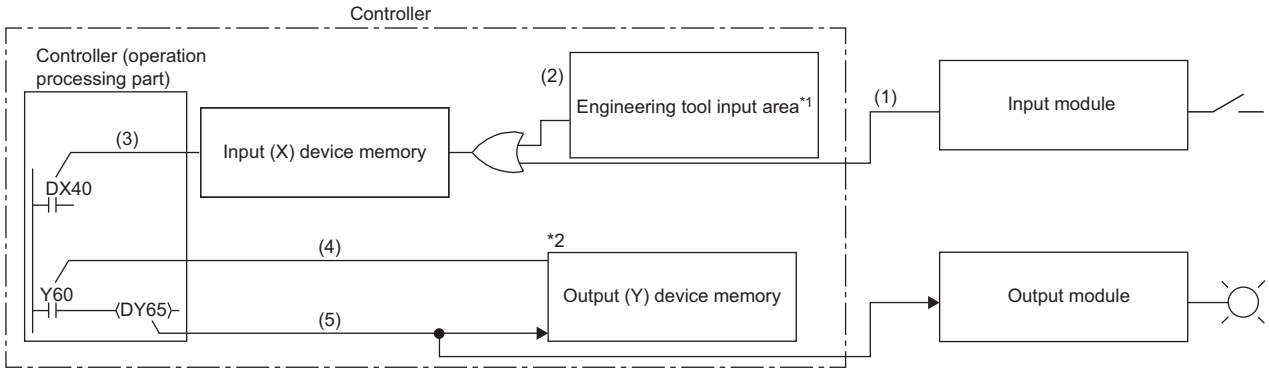


• If data generated for each communication cycle cannot be received over multiple cycles

Received data from the corresponding device will not be transferred to the device/label until the transfer restart condition is satisfied.
The fact that the transfer of receive data to the device/label has stopped is stored in the 'Synchronous communication received data transfer status' (U3E0\G10451 to U3E0\G10706). At this time, Synchronous watchdog counter error (error code: 125AH) or Watchdog counter error (error code: 1A40H) is detected.
To resume the transfer of received data to the device/label, any of the following conditions are to be satisfied.

- A restart request is set in 'Restart transfer of synchronous communication received data' (U3E0\G10708 to U3E0\G10963) and the transfer of received data from the corresponding device is instructed to resume.
- The corresponding device is restarted. (Even if the device is disconnected, it will be reconnected when the device is restarted.)

Direct mode



The controller performs I/O processing when each instruction is executed in a program.

The controller uses direct access input (DX) and direct access output (DY) to perform direct I/O processing.

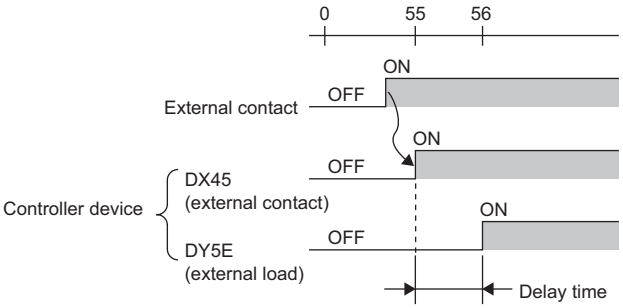
Outline of the processing

The following describes the details of the direct mode.

*1 Data in the engineering tool input area can be turned on or off by the following:
- Test operation of an engineering tool
- Writing data from the network module
- Writing data from an external device using SLMP

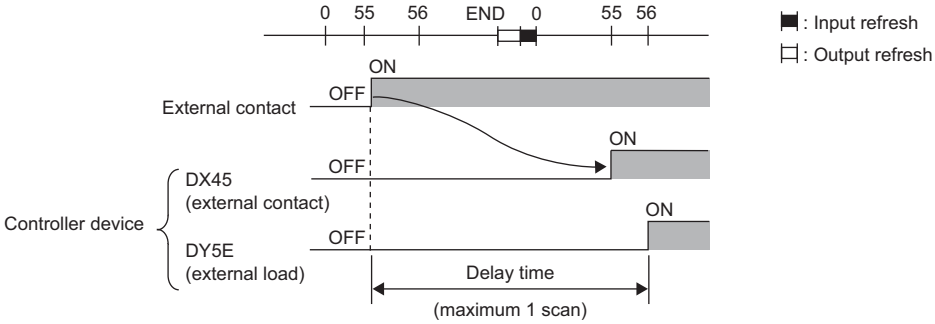
*2 Data in the output (Y) device memory can be turned on or off by the following:
- Test operation of an engineering tool
- Writing data from the network module
- Writing data from an external device using SLMP

Item	Description
Execution of an input contact instruction	The OR processing is executed with the input information of the input module (1) and the input data of the engineering tool input area (2) or remote input refresh area. The result is stored in the input (X) device memory and is used as input data (3) to execute the program.
Execution of an output contact instruction	Output data in the output (Y) device memory (4) are read out and the program is executed.
Execution of the OUT instruction	The operation result of the program (5) is output to the output module, and stored in the output (Y) device memory.



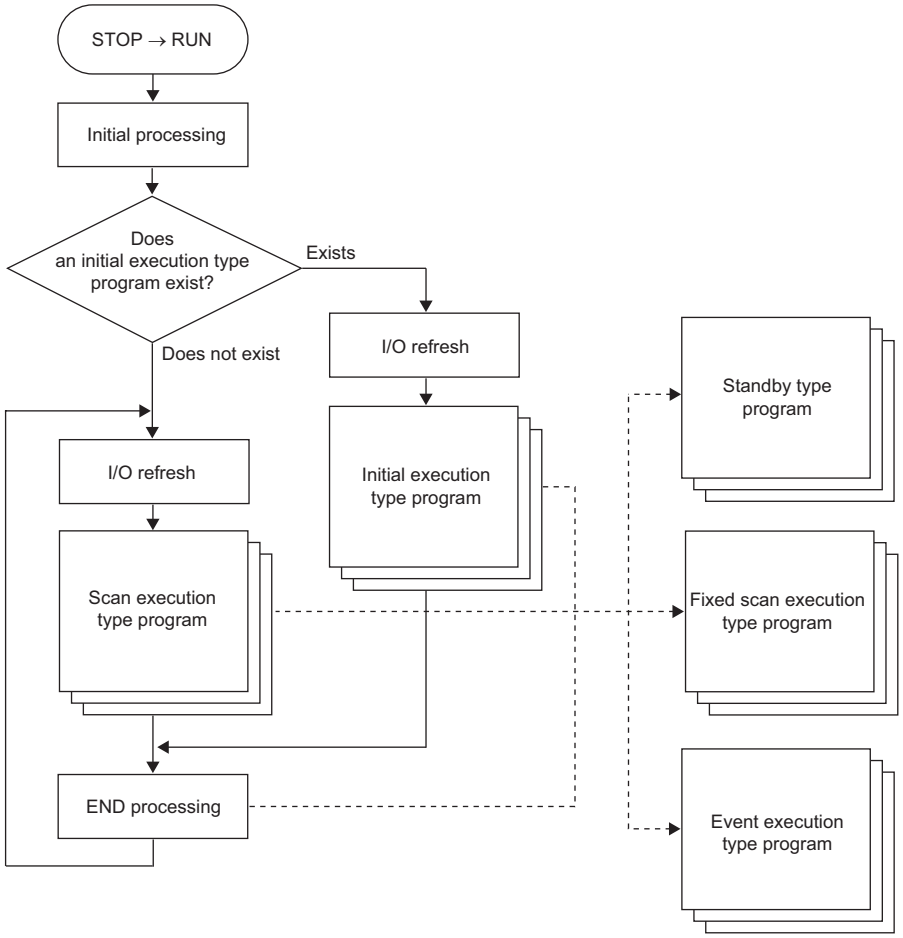
Response delay

An output response which corresponds to the status change in the input module delays for one scan (maximum) depending on the on timing of an external contact.



[Example] A program that turns on the output DY5E when the input DX45 turns on

- Y5E turns on the earliest



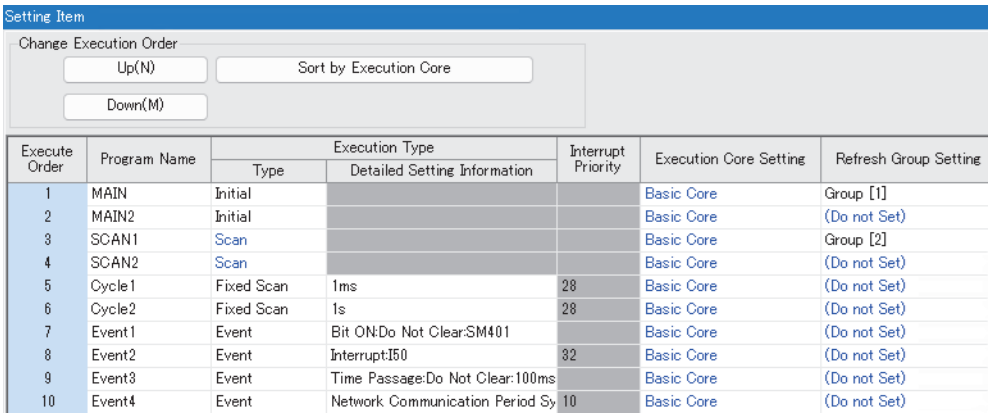
- Y5E turns on the latest

14 RUNNING A PROGRAM

14.1 Program Flow

Programs are executed in order when the controller is switched to the RUN state according to the program execution type and execution sequence settings. (☞ Page 246 Program Execution Type, ☞ Page 258 Execution type change)

Point



Programs with the same execution type are executed according to the execution sequence settings.

14.2 Program Setting

The program setting function is set in "Program Setting" of "CPU Parameter".

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Program Setting]

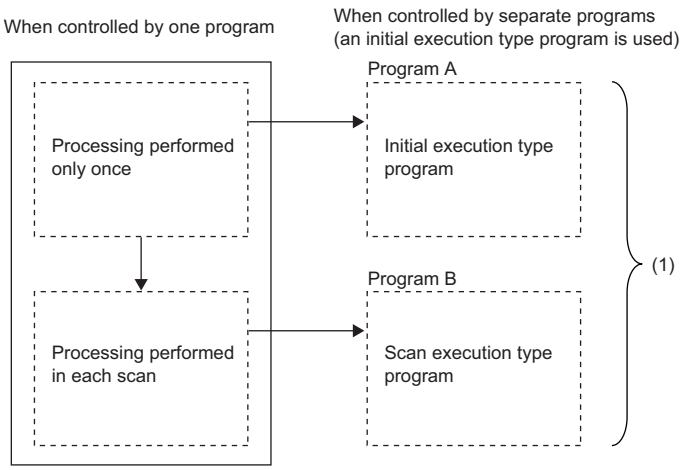
The following is the setting window for the program setting function.

Execute Order	Program Name	Execution Type		Interrupt Priority	Execution Core Setting	Refresh Group Setting
		Type	Detailed Setting Information			
1	MAIN	Initial			Basic Core	Group [1]
2	MAIN2	Initial			Basic Core	(Do not Set)
3	SCAN1	Scan			Basic Core	Group [2]
4	SCAN2	Scan			Basic Core	(Do not Set)
5	Cycle1	Fixed Scan	1ms	28	Basic Core	(Do not Set)
6	Cycle2	Fixed Scan	1s	28	Basic Core	(Do not Set)
7	Event1	Event	Bit ON:Do Not Clear:SM401		Basic Core	(Do not Set)
8	Event2	Event	Interrupt:I50	32	Basic Core	(Do not Set)
9	Event3	Event	Time Passage:Do Not Clear:100ms		Basic Core	(Do not Set)
10	Event4	Event	Network Communication Period Sy	10	Basic Core	(Do not Set)

The items of the program setting function are shown below.

Item		Description	Setting range	Default
Change Execution Order	Up	Moves the execution order of the selected program one step backward.	—	—
	Down	Moves the execution order of the selected program one step forward.	—	—
	Sort by Execution Core	Rearranges the programs so that they are executed in order of the execution cores.	—	—
Execute Order		Indicates the order of program execution.	1 to 380 programs*1	Program creation order
Program Name		Sets the program file name.	1 to 60 characters	—

Item		Description	Setting range		Default
Execution Type	Type	Sets the program execution type.	• Standby • Scan • Initial • Fixed scan • Event		Scan
	Detailed Setting Information	Displays the detailed settings for fixed scan execution type programs and event execution type programs.	■Fixed scan execution type program Sets the fixed scan interval.	Specified Time Intervals: 0.5 to 60000 [ms]/1 to 60 [s]	—
			■Event execution type program Sets a trigger.	■ON of Bit Data (TRUE) Sets the device used as the trigger. • Clear Output and Current Value of Timer: Clear/Do Not Clear	Bit ON: Do Not Clear
				■Interruption Occurrence Sets the interrupt pointer used as the trigger. • I0 to I15, I28 to I31, I48, I49, I50 to I1023	
				■Time Passage Sets the elapsed time that will be the trigger. • Passing Time: 1 to 65535 [ms]/1 to 65535 [s] • Clear Output and Current Value of Timer: Clear/Do Not Clear	
				■Network Communication Period Synchronization Sets the network communication cycle to be synchronized. • Synchronize with Basic Period • Synchronize with Normal-Speed • Synchronize with Low-Speed	
Interrupt Priority		Displays the priority of interrupt programs.	• 1 to 32 (Only the fixed scan execution type and event execution type (when the trigger type is set to Interruption Occurrence or Network Communication Cycle Synchronization) are displayed.) For details on changing the priority, refer to the following. ☞ Page 275 Interrupt Priority Setting		—
Execution Core Setting		Sets the execution core for parallel program execution.	• Basic Core • Extended Core 1 to 3 (only the extended cores set to program execution in the extended core setting)		Basic Core
Refresh Group Setting		Sets a refresh group.	• Group [1] to [64]		(Do not Set)
Device/File Use Or not		Specifies whether to use local device and local index register areas.	Enable		Enable
		Specifies whether to use the initial device value of the local device.	• Use File Setting • Disable		Use File Setting



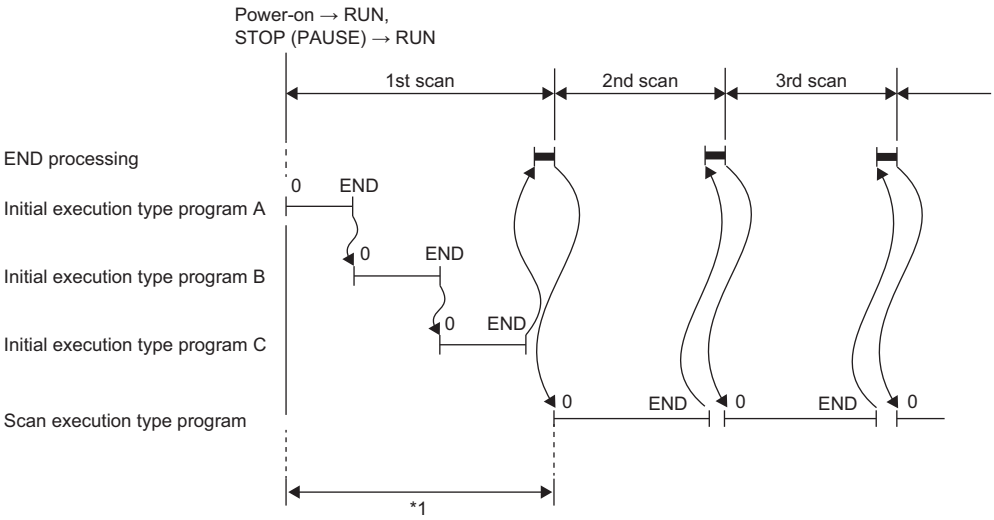
*1 Differs depending on the controller model type. For details on the number of programs, refer to the following.
☞ Page 210 Hardware specifications

14.3 Program Execution Type

Set the execution condition of the program. (☞ Page 258 Execution type change)

Initial execution type program

This program is executed only once when the controller status is changed from the power-on to RUN or from STOP (PAUSE) to RUN. Use this execution type for a program, for example, initial processing for the intelligent function module, which does not need execution after executed once in the initial scan.



(1) The program is divided into the initial execution type program and scan execution type program.

Point

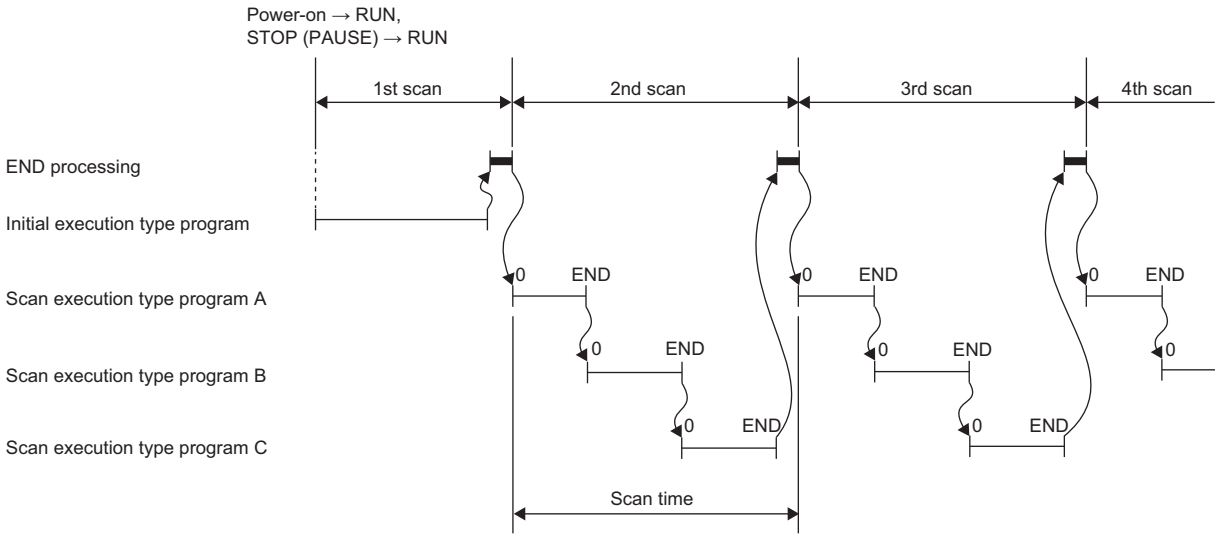
When an initial execution type program is registered, interrupts are disabled during the execution of the initial execution type program in the first scan after the status is changed to RUN, but interrupts are enabled at the execution of the program in the second and subsequent scans.

Note that the execution time of the initial execution type program is the same as the initial scan time. (☞ Page 222 Initial scan time) When multiple initial execution type programs are executed, the execution time of the initial execution type program will be the total time until all the initial execution type programs finish execution.

*1 The sum of the initial execution type program execution time and END processing time is the initial scan time.

Precautions

The following lists the precautions for the initial execution type programs.

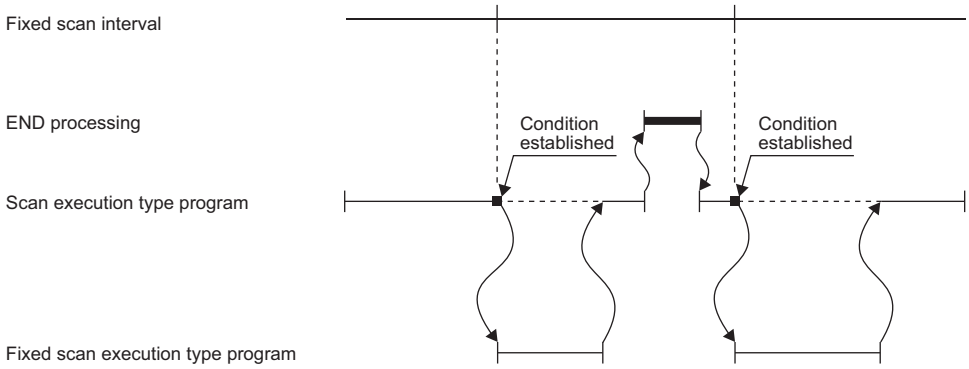


■Restrictions on program creation

In the initial execution type program, do not use an instruction which requires several scans to complete (an instruction with a completion device).

Ex.
Such as the SEND and RECV instructions

Scan execution type program



Scan execution type program is executed only once per every scan starting from the scan following the scan in which the initial execution type program was executed.

When multiple scan execution type programs are executed, the execution time of the scan execution type program will be the total time until all the scan execution type programs finish execution. Note that if interrupt program, fixed scan execution type program, and/or event execution type program are executed before the scan execution type program finishes execution, the execution time for these programs is also included.

Fixed scan execution type program

This is an interrupt program which is executed at specified time intervals. Differently from the normal interrupt program, this type of program does not require the interrupt pointer (I) and the IRET instruction and is executed for each program file unit.

Fixed scan interval setting

Set the execution condition of the fixed scan execution type program.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Program Setting]

Item	Setting
Fixed Scan Interval	
Unit	ms

1. Click "Detailed Setting" on the "Program Setting" window.
2. Select the program name and set the execution type to "Fixed Scan".
3. Click "Detailed Setting Information".
4. Set the fixed scan interval.

Displayed items

Item	Description	Setting range	Default
Fixed Scan Interval	Sets the fixed scan interval to execute the fixed scan execution type program.	• When "ms" is selected: 0.5 to 60000ms (in increments of 0.5ms) • When "s" is selected: 1 to 60s (in increments of 1s)	—
Unit	Selects the unit for the fixed scan interval.	• ms • s	ms

Priority of fixed scan execution type programs

The priority of fixed scan execution type programs can be set. For details, refer to the following.

☞ Page 274 Interrupt priority

Operation when the execution condition is satisfied

The following describes operation of the program.

■If the execution condition is satisfied before the interrupt is enabled by the EI instruction

The program enters the waiting status and is executed when the interrupt is enabled. Note that if the execution condition for this fixed scan execution type program is satisfied more than once during the waiting status, the program is executed only once when the interrupt is enabled.

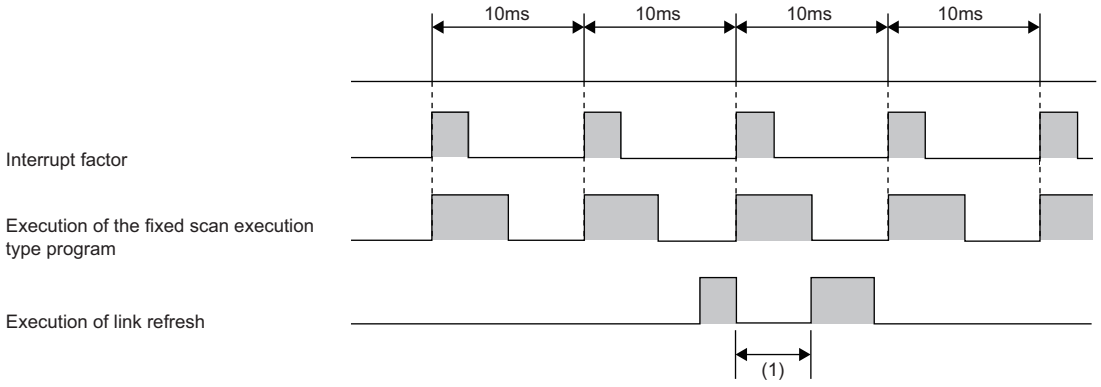
■If there are multiple fixed scan execution type programs

If the specified time comes simultaneously for these programs, they are executed in order according to the specified execution sequence.

■If another or the same execution condition is satisfied while the fixed scan execution type program is being executed

The program is executed according to the fixed scan execution mode setting.

☞ Page 250 Fixed scan execution type program

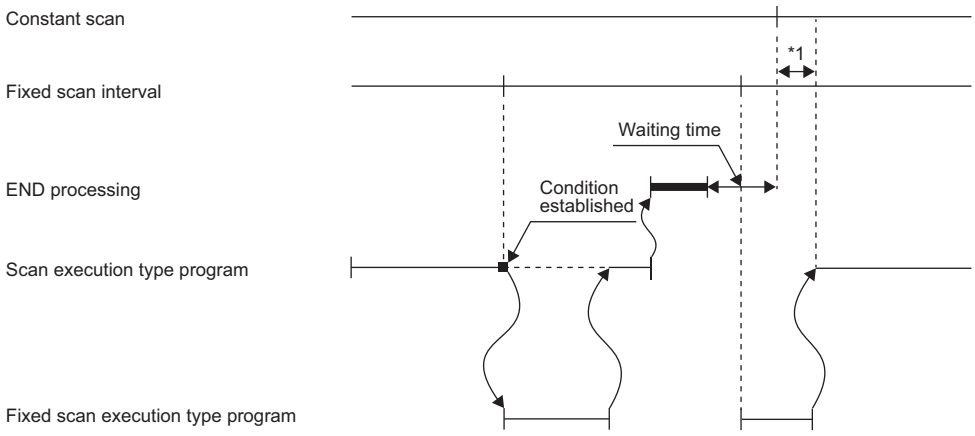


■If the execution condition is satisfied while the interrupt is disabled by the system

The program is executed according to the fixed scan execution mode setting.

☞ Page 250 Fixed scan execution type program

■If an interrupt factor occurs during link refresh



The link refresh is suspended and the fixed scan execution type program is executed. Even while the station-based block data assurance is enabled for cyclic data during refresh of such links as CC-Link IE TSN, if the fixed scan execution type program uses a device specified as the refresh target, the station-based block data assurance for cyclic data is not available.

(1) The link refresh is suspended and the fixed scan execution type program is executed.

■If an interrupt factor occurs during the waiting time after END processing in constant scan execution

The fixed scan execution type program is executed.

*1 If processing does not finish during the waiting time, the scan time is extended.

■If another interrupt occurs while the fixed scan execution type program is being executed

If an interrupt program (including an interrupt which triggers the event execution type program) is triggered while the fixed scan execution type program is being executed, the program operates in accordance with the interrupt priority. (☞ Page 274 Multiple interrupt)

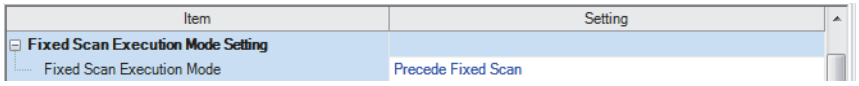
Processing when the fixed scan execution type program starts

The same processing as when the interrupt program starts. (☞ Page 269 Processing at interrupt program startup)

Fixed scan execution mode

For fixed scan interrupts (I28 to I31, I48, I49) triggered by the fixed scan execution type program or the internal timer of the controller, this mode specifies the program execution operation that is performed when more than one interrupt occurs. (☞ Page 262 Operation upon occurrence of an interrupt factor) However, when an execution cause occurs while the interrupt is disabled by the DI instruction or during the execution of the online program change function, the fixed scan execution mode is excluded from the target.

For the online change, refer to the following.



☞ Page 1594 Online Change

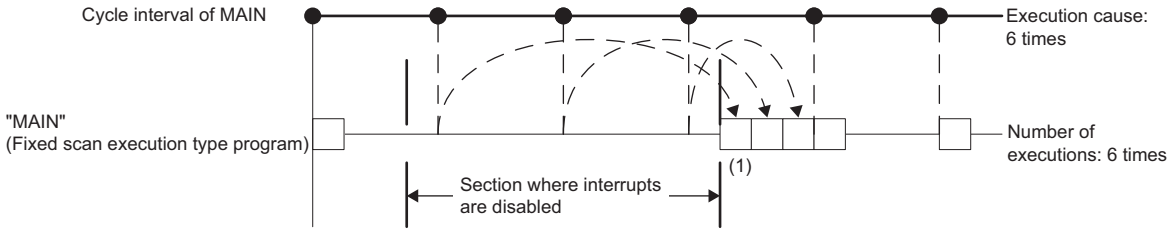
■Fixed scan execution mode setting

Use the fixed scan execution mode setting.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Interrupt Settings] ⇨ [Fixed Scan Execution Mode Setting]

Window

Displayed items

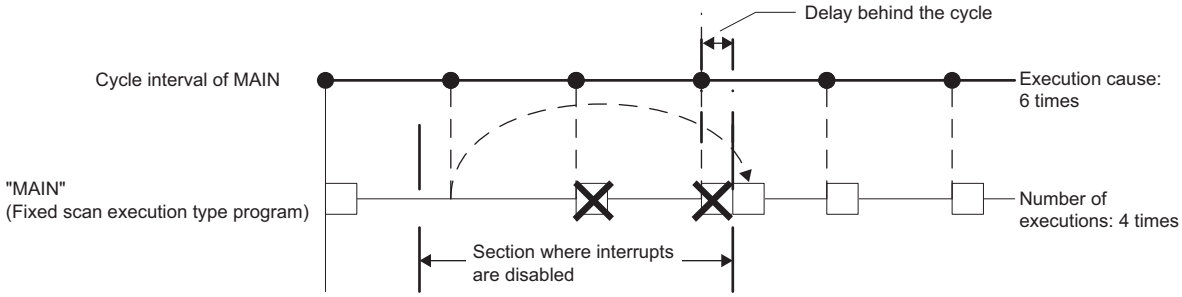


Item	Description	Setting range	Default
Fixed Scan Execution Mode	When fixed scan characteristics are prioritized, an execution is performed within the delay limit value behind a cycle. When the number of executions is prioritized, all the pending executions are performed.	• Precede Fixed Scan • Execution Count Takes Priority	Precede Fixed Scan

■Operation in the fixed scan execution mode

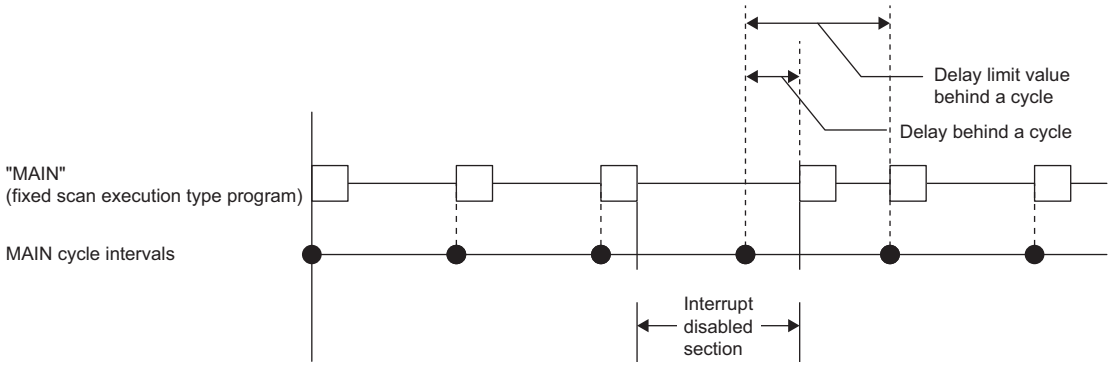
This section describes the operation which can be performed in the fixed scan execution mode.

• Execution Count Takes Priority



The program is executed for all the pending number of executions so that it can be executed the same number of times as execution causes.

(1) The three pending executions will be executed immediately after an interrupt becomes available.



• Precede Fixed Scan

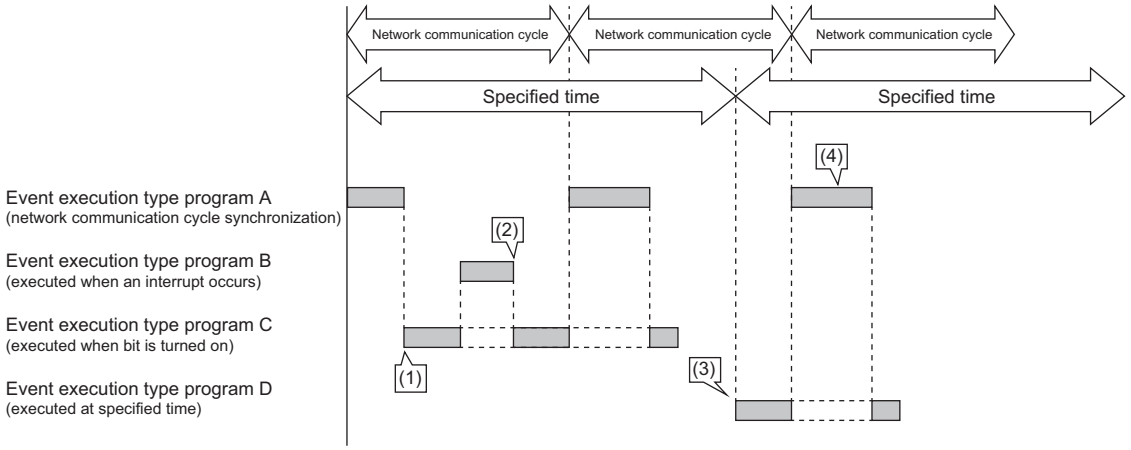
When a pending execution exists, it is performed within the delay limit value behind a cycle. (☞ Page 251 Delay limit value behind a cycle) Note that, even if more than one pending execution exists, only one execution is performed.

■Delay limit value behind a cycle

This value indicates the allowable period of time for a delay (a time lag) behind a cycle and a waiting program is executed if an interrupt is enabled within the period. If an interrupt is enabled outside the period, the program is not executed.

The delay limit value behind a cycle differs as follows.

• For the fixed scan execution type program



The execution cycle set to each program becomes the delay limit value. For example, if there are fixed scan execution type programs with 2ms, 4ms, and 12ms scan periods, the delay limit value behind a cycle is 2ms, 4ms, and 12ms.

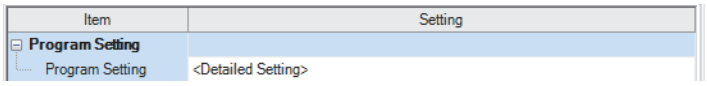
• For fixed scan interrupts (I28 to I31, I48, I49) using the internal timer of the controller

The value is fixed to the same value as the fixed scan interval. For example, if the periods are I28: 100ms and I29: 20ms, the delay limit value behind a cycle is 100ms for I28, and 20ms for I29.

Event execution type program

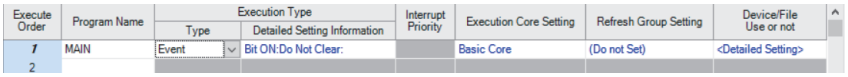
This type of program starts execution when triggered by a specified event. The program is executed in the order specified by the program settings of the CPU parameters. If the execution conditions of the specified trigger are met when the execution turn of the event execution type program comes, the program is executed.

No.	Item	Description	Reference
(1)	ON of Bit Data (TRUE)	When the event execution type program becomes the target for execution according to the program setting order, if the specified bit data is on (TRUE), the program is executed once.	Page 254 ON of Bit Data (TRUE)
(2)	Interruption Occurrence	When the specified interrupt factor occurs, the program is immediately executed once.	Page 255 Interruption Occurrence
(3)	Passing Time	After the controller has entered the RUN state and the specified time has elapsed, the event execution type program is executed once.	Page 256 Passing Time
(4)	Network Communication Period Synchronization	The event execution type program is executed in synchronization with the network communication cycle.	Page 256 Network Communication Period Synchronization



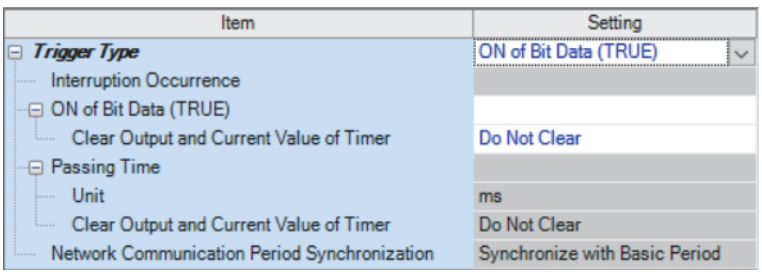
Trigger setting

Use the event execution type detail setting.



Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Program Setting]

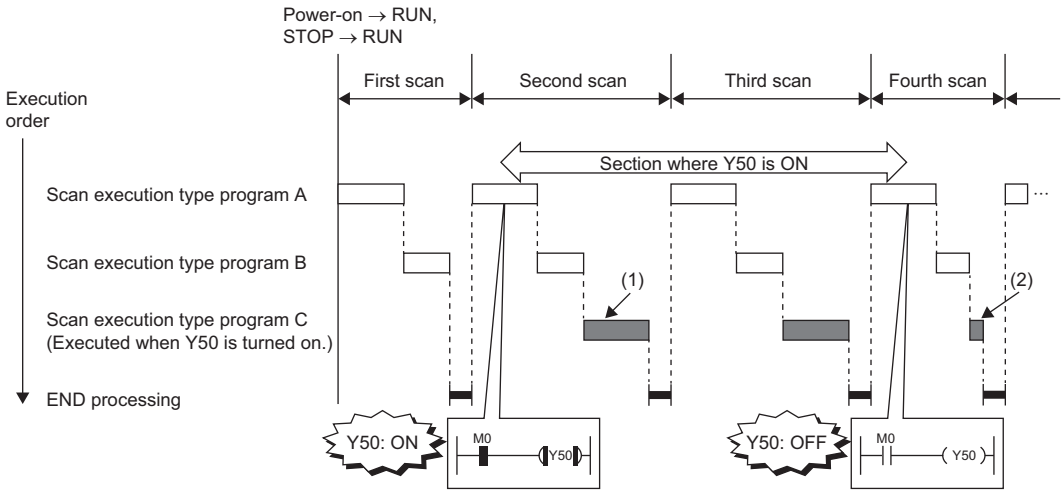
Operating procedure



"Program Setting" window

"Detailed Setting" window

"Event Execution Type Detailed Setting" window



1. Click "Detailed Setting" on the "Program Setting" window.
2. Select the program name and set the execution type to "Event".
3. Click "Detailed Setting Information".
4. Sets the trigger type to execute the event execution type program.

Displayed items

Item		Description	Setting range	Default
Trigger Type		Sets the trigger type for the event execution type program.	• ON of Bit Data (TRUE) • Interruption Occurrence • Passing Time • Network Communication Period Synchronization	ON of Bit Data (TRUE)
ON of Bit Data (TRUE)	—	Sets the device used as the trigger.	☞ Page 254 Delay limit value behind a cycle	—
	Clear Output and Current Value of Timer	Sets that the current values of the output (Y), timer (T), and long timer (LT) used in this program are cleared at the execution order of the event execution type program that comes after the specified bit data is off.	• Do Not Clear • Clear	Do Not Clear
Interruption Occurrence		Sets the interrupt pointer used as the trigger.	I0 to I15, I28 to I31, I48, I49, I50 to I1023	—
Passing Time	Unit	Sets the time passed.	• When "ms" is selected: 1 to 65535ms (in units of 1ms) • When "s" is selected: 1 to 65535s (in units of 1s)	ms
	Clear Output and Current Value of Timer	Sets that the current values of the output (Y), timer (T), and long timer (LT) used in this program are cleared at the execution order of the event execution type program that comes after the specified time passes.	• Do Not Clear • Clear	Do Not Clear
Network Communication Period Synchronization		Sets the network communication cycle to be synchronized as a trigger.	• Synchronize with Basic Period • Synchronize with Normal-Speed • Synchronize with Low-Speed	Synchronize with Basic Period

ON of Bit Data (TRUE)

The program is executed at the execution order specified in program setting of the CPU parameters, and if the specified bit data is on (TRUE) when the execution order of the event execution type program comes, the program is executed. The current values of the output (Y), timer (T), and long timer (LT) used in this program can be cleared at the execution order that comes after the specified bit data is changed from on (TRUE) to off (FALSE).

(1) If Y50 is on when the execution order of the event execution type program C comes, the program is executed. If Y50 is off, the program is not executed.
(2) When "Clear Output and Current Value of Timer" is set, the current values of the output (Y), timer (T), and long timer (LT) used in this program are cleared at the execution order of the event execution type program that comes after Y50 is off.

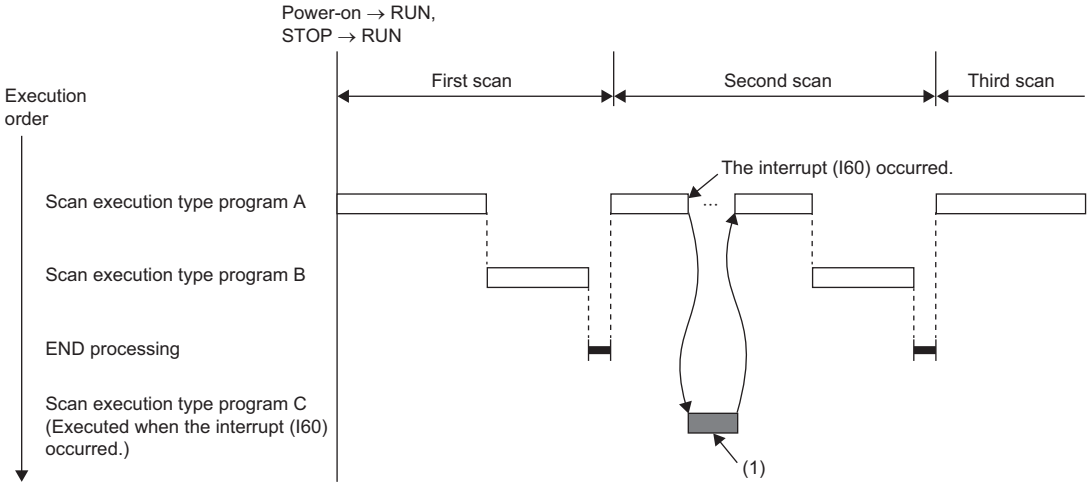
Applicable devices are as follows.

Item		Description
Device*1	Bit device	X (DX), Y, M, L, F, SM, B, SB, Jn\X, Jn\Y, Jn\B, Jn\SB
	Bit specification of word device	D, SD, W, SW, R*2, ZR*2, RD, Un\G, Jn\W, Jn\SW

*1 A local device or index-modified device cannot be specified.
*2 If no file register is assigned or if specification is out of the range, interrupt is not turned on (TRUE).

Precautions

Note the following when specifying the link device assigned to the synchronous station of the CC-Link IE TSN function.



- Specify the refresh target device or label of the same link device.
- Depending on U□\G□ (module access device) and Jn\□ (link direct device), if the same link device is specified, the trigger will not be established.

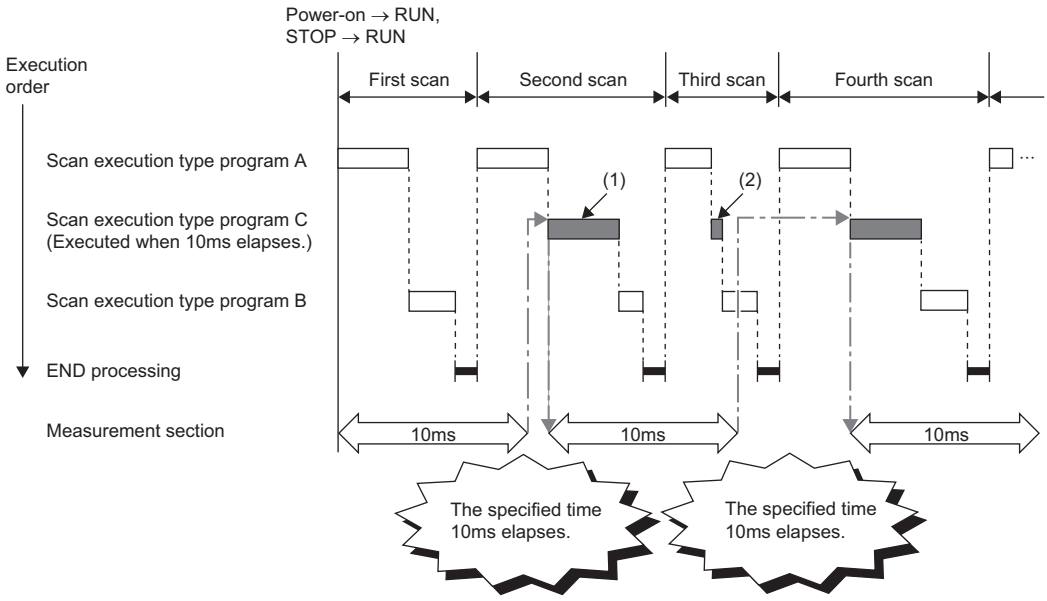
Point

To measure the timer and the retentive timer continuously even when the trigger execution condition of the event execution type program is not met, use the long timer (LT) and the long retentive timer (LST). The timer (T) and the retentive timer (ST) can be used in the event execution type program. However, they do not measure time when the trigger execution condition of the event execution type program is not met. Set "Clear Output and Current Value of Timer" to "Clear" when using the timer (T) and the retentive timer (ST).
(☞ Page 252 Trigger setting)
Note that if the above parameter is set, the use of the long timer (LT) and the long retentive timer (LST) is limited to the same as that of the timer (T) and the retentive timer (ST). (They do not measure time continuously when the trigger execution condition of the event execution type program is not met.)

Interruption Occurrence

When the specified interrupt factor occurs, the program is immediately executed once. Enabling programs to be independently executed as interrupt programs, this method eliminates the need to write the FEND instruction, interrupt pointers, and the IRET instruction within scan execution type programs.

(1) When an interrupt occurs, the event execution type program C is executed immediately.



Interrupt pointers (I) which can be specified are I0 to I15, I28 to I31, I48, I49, I50 to I1023.

Point

Execution conditions for the event execution type program which is triggered by interrupt occurrence are the same as those for general interrupt programs. (☞ Page 262 Operation upon occurrence of an interrupt factor)

Passing Time

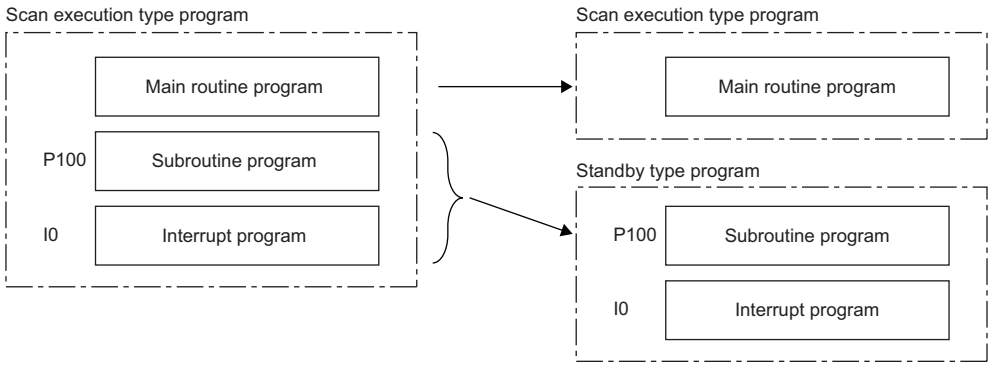
After the status of the controller is changed into the RUN state, programs are executed in execution order specified in "Program Setting" of "CPU Parameter". If the specified time passes, the event execution type program is executed once when the execution order of the program comes. The time is measured again starting from the program execution and the above operation is repeated. This method can be used when the processing is executed periodically after the specified time passes. This method is not for the interrupt execution which another program execution is interrupted and processed to secure the punctuality. Whether to clear the current values of the output (Y), timer (T), and long timer (LT) used in this program can be selected at the execution order that comes after the specified time passes.

(1) After the specified time elapses, the event execution type program C is executed when the execution order of the program comes.
(2) When "Clear Output and Current Value of Timer" is set, the current values of the output (Y), timer (T), and long timer (LT) used in this program are cleared at the execution order of the event execution type program that comes after the specified time elapses.

Point

To measure time when the trigger type is set to "Passing Time", use the long timer (LT) and the long retentive timer (LST).

Network Communication Period Synchronization



The event execution type program is executed in synchronization with the network communication cycle.
For details, refer to the following.
☞ Page 295 Program Execution Synchronized with Communication Cycle

Standby type program

This type of program is executed only when its execution is requested.

Librarization of programs

Set a subroutine program and/or an interrupt program as a standby type program to manage them separately from the main routine program. In a single standby type program, multiple subroutine programs and interrupt programs can be created.

Program arrangement change

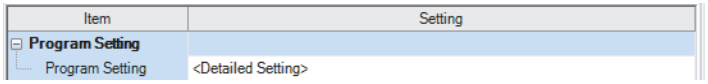
Prepare programs available in all systems to use them only when necessary.

Execution method

The standby type program creates a subroutine program and interrupt program within its program, and then calls them when an interrupt occurs or by specifying with a pointer.

Execution type change

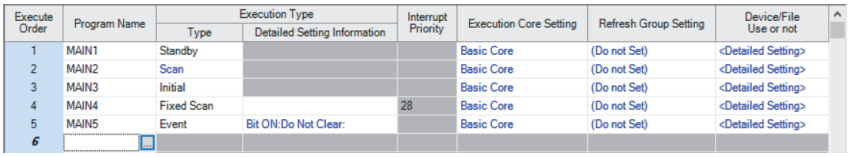
This section describes how to change the execution type of programs.



Using parameter settings

"Program Setting" can be used to specify the execution type of programs.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Program Setting] ⇨ [Detailed Setting]



Operating procedure

"Program Setting" window

Item	Setting
Program Setting	
Program Setting	<Detailed Setting>

5	MAIN5	Event	Bit ON:Do Not Clear:		Basic Core	(Do not Set)	<Detailed Setting>
6							

1. Click "Detailed Setting" on the "Program Setting" window.

2. For each program, select the execution type in "Type" of "Execution Type".

Group setting for refresh

Refresh can be performed when a specified program is executed[*1] by setting a group number to each program and specifying the number for each module.

*1 Input refresh (load of analog input, Input (X)) is performed before execution of a program, and output refresh (analog output, Output (Y)) is performed after execution of a program.

Refresh group setting

A group number is set to each program.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Program Setting] ⇨ [Program Setting] ⇨ [Detailed Setting]

Displayed items

Item	Description	Setting range	Default
Refresh Group Setting	Set the group number of each program which is specified for each module.	• Do not Set • Group [1] to [64]	Do not Set

Point

When the specified group number is not set in the refresh settings of each module, the program is executed, but the refresh of the relevant group number is not executed.

Refresh setting of each module

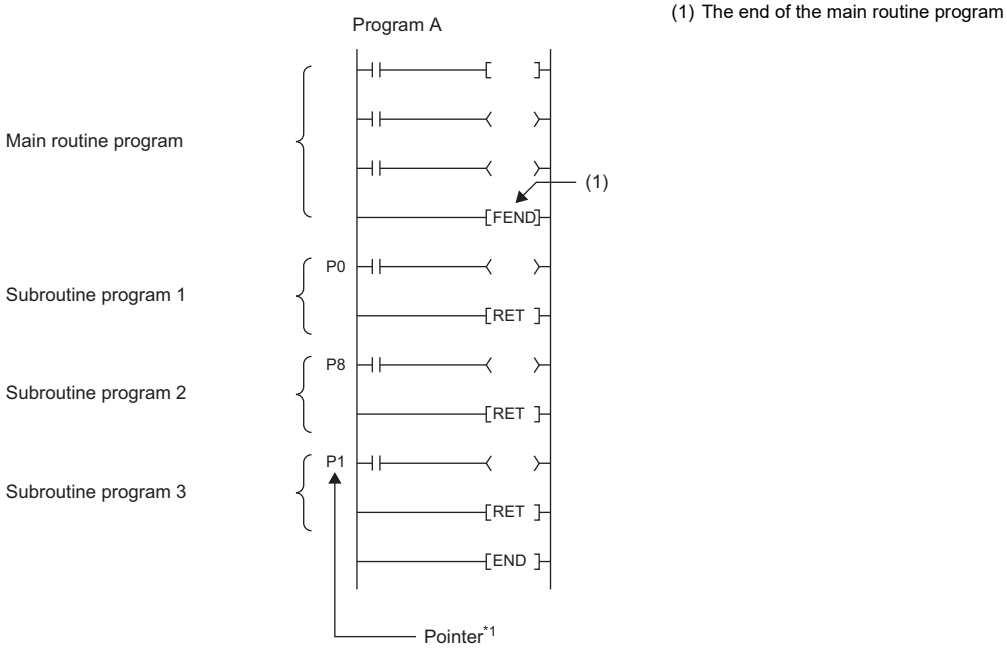
Select "At the execution time of specified program" in "Refresh Setting" of each module, and type the group number of the program to be refreshed.

[Module Parameter] ⇨ [Refresh Setting]

Window

Item	Setting Value
Refresh by the Set Timing	
Refresh Timing	Set refresh timing.
Refresh Timing	At the Execution Time of Specified Program
Refresh Group[n](n:1-64)	1

(Example: The "Refresh Setting" window for an I/O module)



Point

For refresh of each module, refer to the manual for the module used.

14.4 Subroutine Program

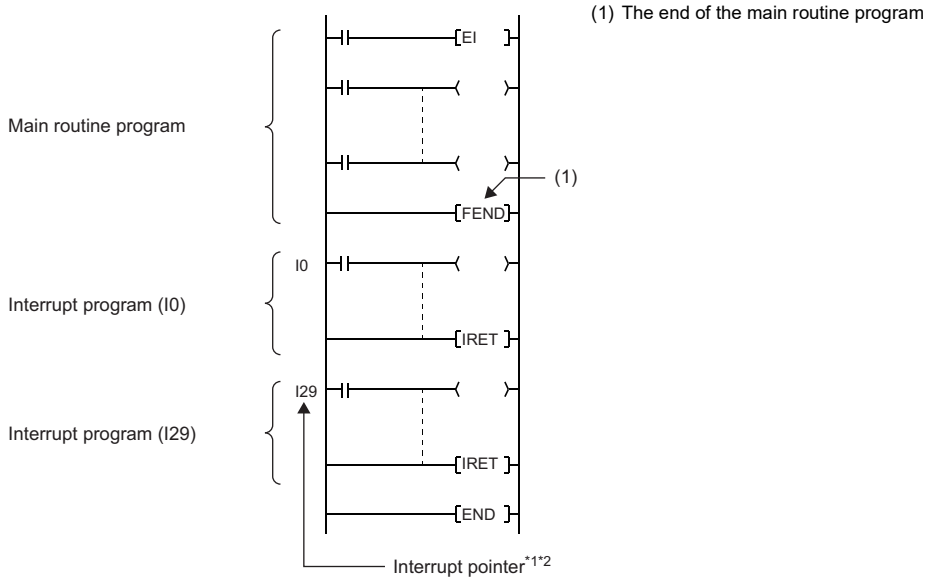
Subroutine program is a program that is executed from a pointer (P) through the RET instruction. It is executed only when called by a subroutine call instruction (such as the CALL instruction or the ECALL instruction). A pointer type label can also be used instead of a pointer (P). The subroutine program is used for the following purposes.

- By grouping programs executed multiple times in a single scan into a single subroutine program, the total number of steps in a single program can be decreased.
- By making a program which is only executed in a certain condition a subroutine program, the scan time can be shortened for that program execution.

*1 The pointers are not required to be defined in an ascending order.

Point

- Making a program a standby type allows it to be managed as a separate program. (☞ Page 257 Standby type program) Use the ECALL instruction and other similar instructions to call program files.
- For details on nesting (nesting structure) of subroutine programs, refer to the nesting (N). (📖MELSEC MX Controller MX-R Model Programming Manual)

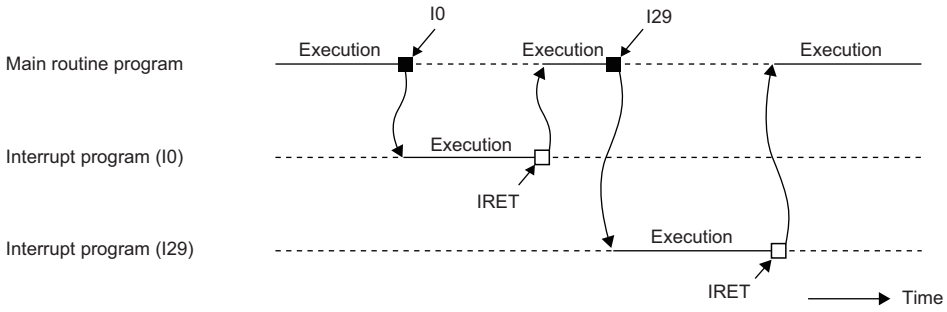


Precautions

The following lists the precautions when using the subroutine program.

- When using a local device, setting of SM776 (Local device setting at CALL) allows for using a local device of a program file at the storage location of the subroutine program.
- Do not use the timer (T, ST). However, the timer can be used if the timer coil (the OUT T☐ instruction) is executed only once per scan.
- When the call occurs, if the RET instruction is not used to return to the calling program and then the program is terminated, an error will occur.
- If a pointer (P) or pointer type global label exists within FB or FUN, an error will occur.

14.5 Interrupt Program



A program from an interrupt pointer (I) through the IRET instruction.

*1 Only one interrupt program can be created with a single interrupt pointer number.

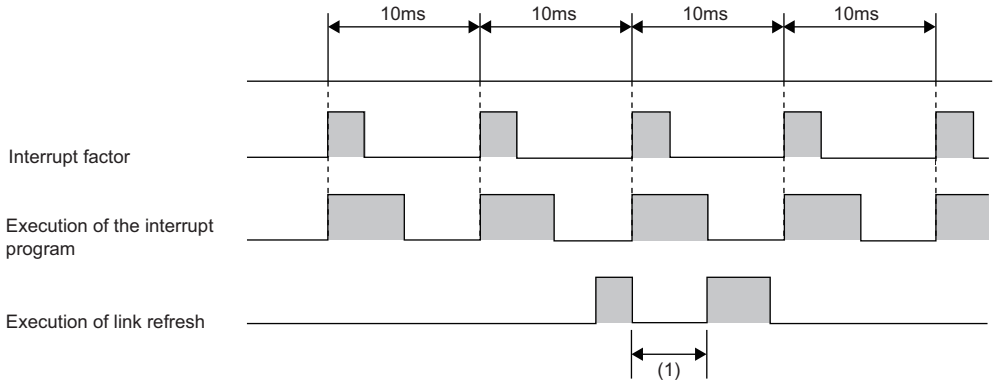
*2 The interrupt pointers are not required to be defined in an ascending order.

When an interrupt factor occurs, the interrupt program corresponding to its interrupt pointer number is executed. (☞ Page 389 Priority for the interrupt pointer numbers and interrupt factors)

I0: Interrupt factor for I0

I29: Interrupt factor for I29

Point



Making a program a standby type allows it to be managed as a separate program. (☞ Page 257 Standby type program)

Operation upon occurrence of an interrupt factor

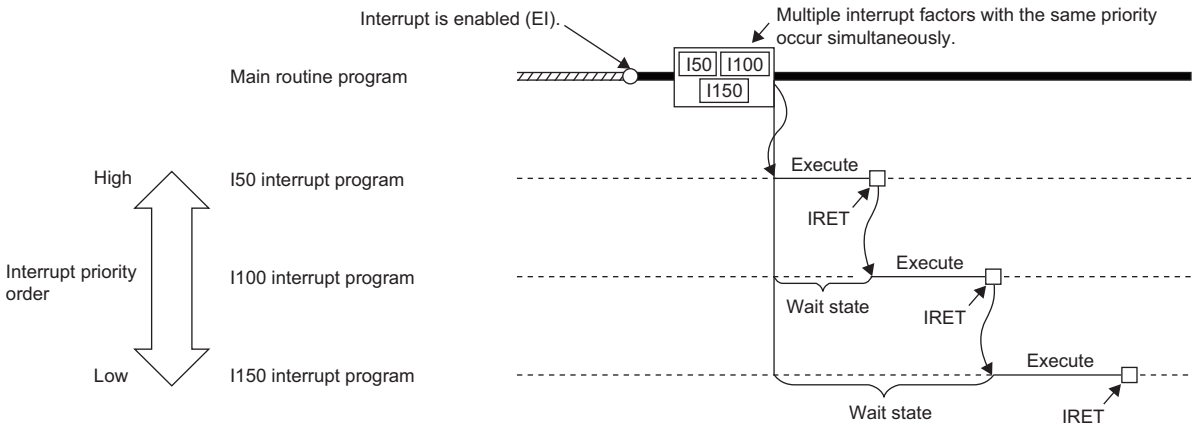
The following shows the operation when an interrupt factor occurs.

If an interrupt factor occurs during link refresh

The link refresh is suspended and the interrupt program is executed. Even though the station-based block data assurance is enabled for cyclic data during refresh of such links as CC-Link IE TSN, if the interrupt program uses a device specified as the refresh target, the station-based block data assurance for cyclic data is not available.

(1) The link refresh is suspended and the interrupt program is executed.

If an interrupt factor occurs during the waiting time after END processing in constant scan execution



The interrupt program for the interrupt factor is executed.

If another interrupt occurs while the interrupt program is being executed

If an interrupt such as a fixed scan execution type program (including an interrupt which triggers the event execution type program) is triggered while an interrupt program is being executed, the program operates in accordance with the interrupt priority. (☞ Page 274 Interrupt priority)

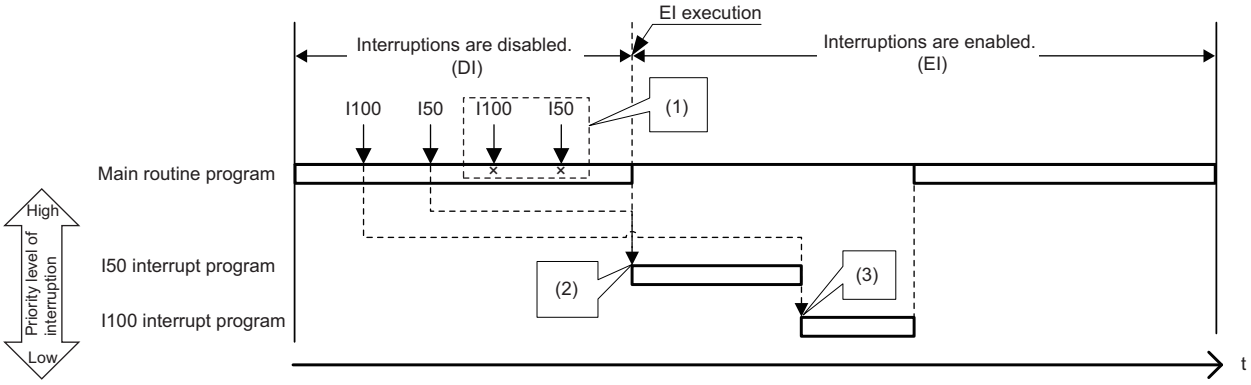
If multiple interrupt factors occur simultaneously while the interrupt is enabled

The interrupt programs are executed in the order of priority. If multiple interrupts with the same interrupt priority occur simultaneously, the interrupt programs are executed in the order of interrupt priority. (☞ Page 276 Interrupt priority order)
The following example shows how multiple interrupts with the same priority occur simultaneously.

Varying operation depending on the interrupt factor

A list of interrupt pointers and interrupt factors is shown below.

For details on interrupt factors, refer to the following.



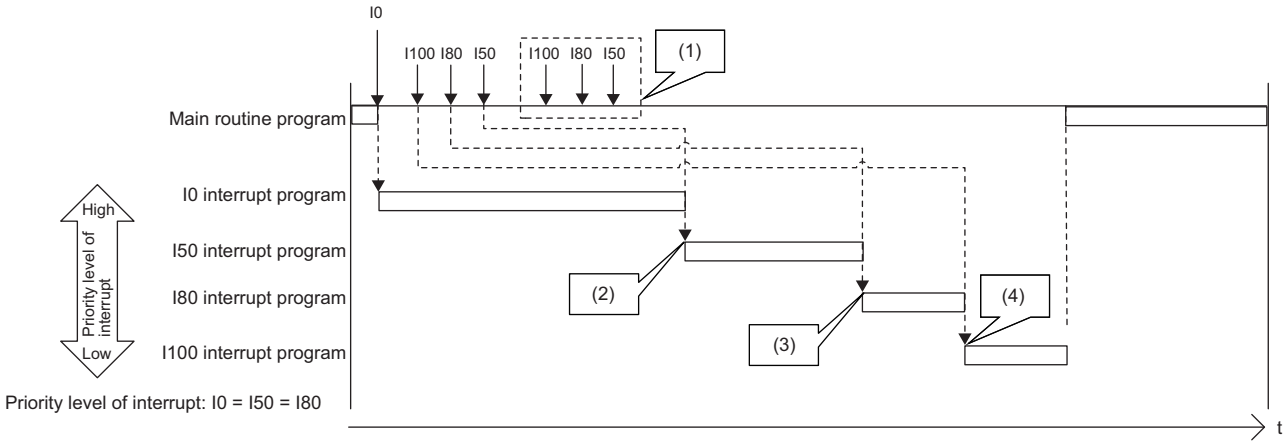
☞ Page 388 Interrupt Pointer (I)

Interrupt factor	Interrupt pointer	Description
Interrupt from module	I0 to I15, I50 to I1023	This interrupt is used for modules which have the interrupt function.
Interrupt by the internal timer	I28 to I31	This interrupt is used in fixed scan interrupts by the internal timer.
High-speed internal timer interrupt 2	I48	This interrupt is used in fixed scan interrupts by the internal timer.
High-speed internal timer interrupt 1	I49	

Interrupt from module (I0 to I15, I50 to I1023)

■If an interrupt factor occurs while interrupt is disabled (DI)

The interrupt factor that has occurred is memorized, and the interrupt program corresponding to the factor will be executed when the interrupt is enabled. Even if the same interrupt factor occurs multiple times, it will be memorized only once. If the IMASK instruction and SIMASK instruction are used to disable the interrupt, all the memorized factors will be discarded.

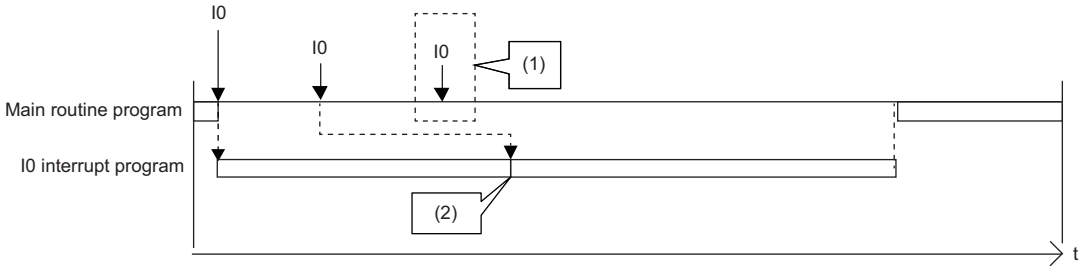


(1) The second and following interrupt factors that occur while interrupts have been disabled (DI) are not memorized.

(2) When interrupts are enabled, interrupts are executed in order from I50 because it has a higher priority.

(3) I100 is executed. (I50 is not executed for the second time.)

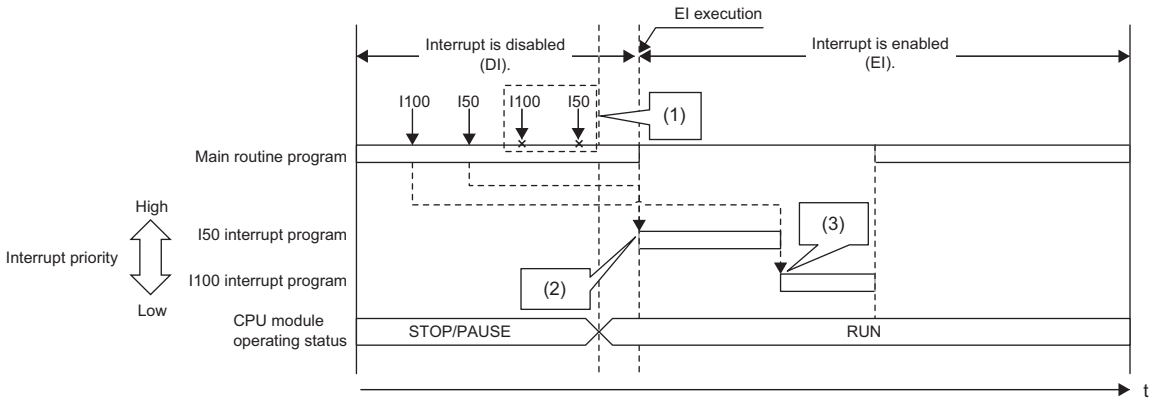
■If an interrupt factor with the same or a lower priority occurs while the interrupt program is being executed



The interrupt factor that has occurred is memorized. After the running interrupt program finishes, the interrupt program corresponding to the factor will be executed. Even if the same interrupt factor occurs multiple times, it will be memorized only once.

(1) The second and following interrupt factors that occur while interrupts have been disabled (DI) are not memorized.
(2) After the interrupt in execution is completed, interrupts are executed in order from I50 because it has a higher priority. Although both I50 and I80 have the same priority level, I50 is executed ahead of I80 because I50 has a higher priority order.
(3) I80 is executed. (I50 is not executed for the second time.)
(4) I100 is executed. (I80 is not executed for the second time.)

■If the same interrupt factor occurs while the interrupt program is being executed



The interrupt factor that has occurred is memorized. After the running interrupt program finishes, the interrupt program corresponding to the factor will be executed. Even if the same interrupt factor occurs multiple times, it will be memorized only once.

(1) The second and following interrupt factors that occur while interrupts are executed are not memorized.
(2) After the interrupt in execution is completed, the first interrupt program is executed.

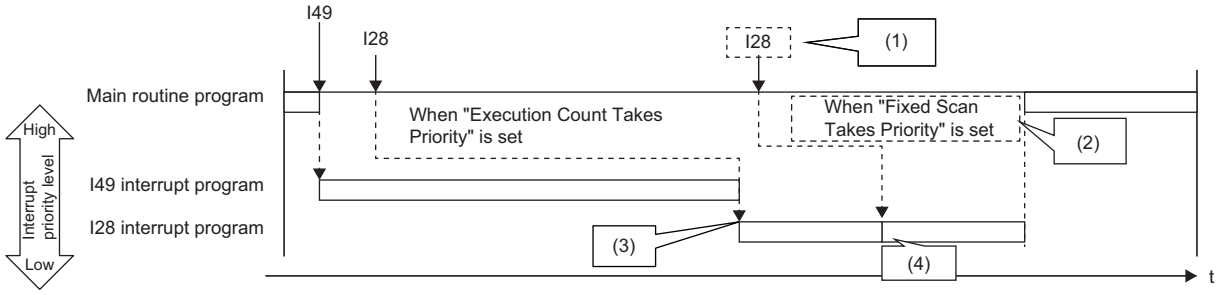
■If an interrupt factor occurs in the STOP/PAUSE state

The interrupt factor that has occurred is memorized, and the corresponding interrupt program will be executed when the controller switches to the RUN state and the interrupt is enabled. Even if the same interrupt factor occurs multiple times before switching to the RUN state, it will be memorized only once.

(1) The second and following interrupt factors that occur while the controller is in the STOP state are not memorized.
(2) When interrupts are enabled by changing the operating status of the controller from STOP to RUN, interrupts are executed in order from I50 that has a higher priority level.
(3) I100 is executed. (I50 is not executed for the second time.)

Internal timer interrupts (I28 to I31), high-speed internal timer interrupts (I48, I49)

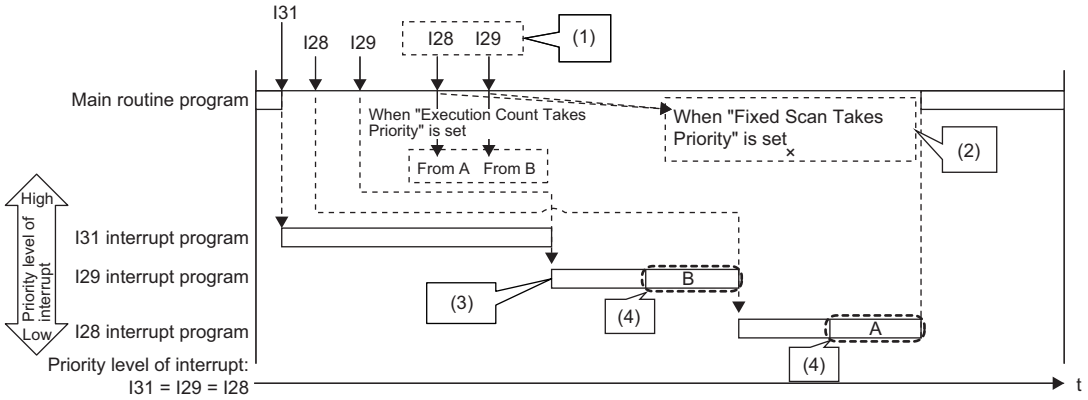
■If an interrupt factor occurs while interrupt is disabled (DI)



For details, refer to the following.

☞ Page 263 If an interrupt factor occurs while interrupt is disabled (DI)

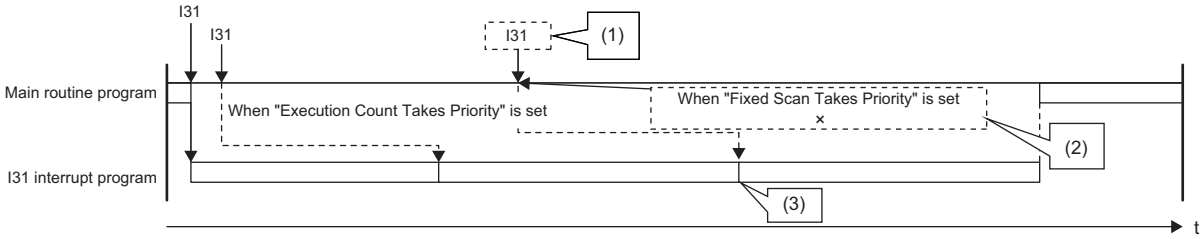
■If an interrupt factor with the same or a lower priority occurs while the interrupt program is being executed



The interrupt factor that has occurred is memorized. After the running interrupt program finishes, the interrupt program corresponding to the factor will be executed. If the same interrupt factor occurs multiple times, it will be memorized once but operation at the second and later occurrences depends on the setting of the fixed scan execution mode. (☞ Page 250 Fixed scan execution mode) When "Execution Count Takes Priority" is enabled, the interrupt program corresponding to the memorized interrupt factor will be executed after the running interrupt program finishes. When "Precede Fixed Scan" is enabled, the second and later interrupt factors will not be memorized.

When interrupts with lower priority level than the one being executed occur

(1) The second and following interrupt factors that occur while interrupts are being executed operate according to the setting of the fixed scan execution mode.
(2) The program is not executed for the second time.
(3) After the interrupt in execution is completed, interrupts are executed in order from I28 because it has a higher priority.
(4) The second interrupt is executed.



When interrupts with the same priority level as the one being executed occur

(1) The second and following interrupt factors that occur while interrupts are being executed operate according to the setting of the fixed scan execution mode.
(2) The program is not executed for the second time.
(3) After the interrupt in execution is completed, interrupts are executed in order from I29 because it has a higher priority.
(4) The second interrupt is executed.

■If the same interrupt factor occurs while the interrupt program is being executed

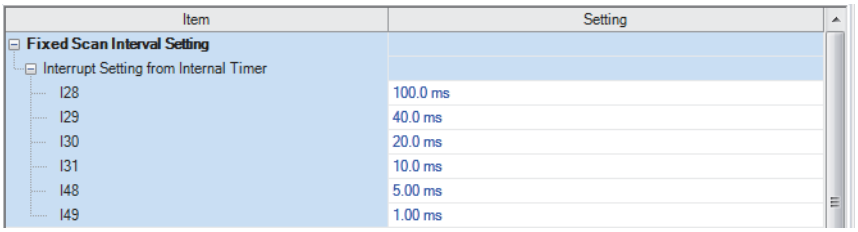
The interrupt factor that has occurred is memorized. After the running interrupt program finishes, the interrupt program corresponding to the factor will be executed. If the same interrupt factor occurs multiple times, it will be memorized once but operation at the second and later occurrences depends on the setting of the fixed scan execution mode. (☞ Page 250 Fixed scan execution mode) When "Execution Count Takes Priority" is enabled, the interrupt program corresponding to the memorized interrupt factor will be executed after the running interrupt program finishes. When "Precede Fixed Scan" is enabled, the second and later interrupt factors will not be memorized.

(1) The second and following interrupt factors that occur while interrupts are being executed operate according to the setting of the fixed scan execution mode.
(2) The program is not executed for the second time.
(3) The second interrupt is executed.

■If an interrupt factor occurs in the STOP/PAUSE state

For details, refer to the following.

☞ Page 265 If an interrupt factor occurs in the STOP/PAUSE state



Interrupt period setting

The interrupt cycle based on the internal timer can be specified.

Fixed Scan Interval Setting

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Interrupt Settings] ⇨ [Fixed Scan Interval Setting]

Window

Displayed items

Item	Item	Description	Setting range	Default
Interrupt Setting from Internal Timer	I28	Sets the execution interval of I28.	0.5 to 1000ms (in units of 0.5ms)	100.0ms
	I29	Sets the execution interval of I29.		40.0ms
	I30	Sets the execution interval of I30.		20.0ms
	I31	Sets the execution interval of I31.		10.0ms
	I48	Sets the execution interval of I48.	0.05 to 1000ms (in units of 0.05ms)	5.00ms
	I49	Sets the execution interval of I49.		1.00ms

Processing at interrupt program startup

The processing shown below is performed when the interrupt program starts.

- Saving/restoring of the file register (R) block number
- Saving/restoring of the index register (Z, LZ)

Saving/restoring of the file register (R) block number

When an interrupt program starts, the block number of the file register (R) of the running program is saved and passed to the interrupt program. Also, when the interrupt program finishes, the saved block number is restored to the running program.

■Block No. Save/Recovery Setting

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Interrupt Settings] ⇨ [Block No. Save/Recovery Setting]

Window

Displayed items

Item	Description	Setting range	Default
File Register (R) Block No. of Basic Core	Sets whether or not the block number of the file register (R) is saved/restored when an interrupt program is being executed in the main core.	• Not Saved/ Recovered • Save/Recover	Save/Recover

Point

When the block number of the file register (R) is not changed in an interrupt program, enabling "Not Saved/ Recovered" can reduce the startup time and the termination time of the interrupt program. (☞ Page 2086 Interrupt program overhead time)
To change the block number of the file register (R) while "Not Saved/Recovered" is enabled, the block number of that file register (R) must be saved/restored by the program.

Restriction

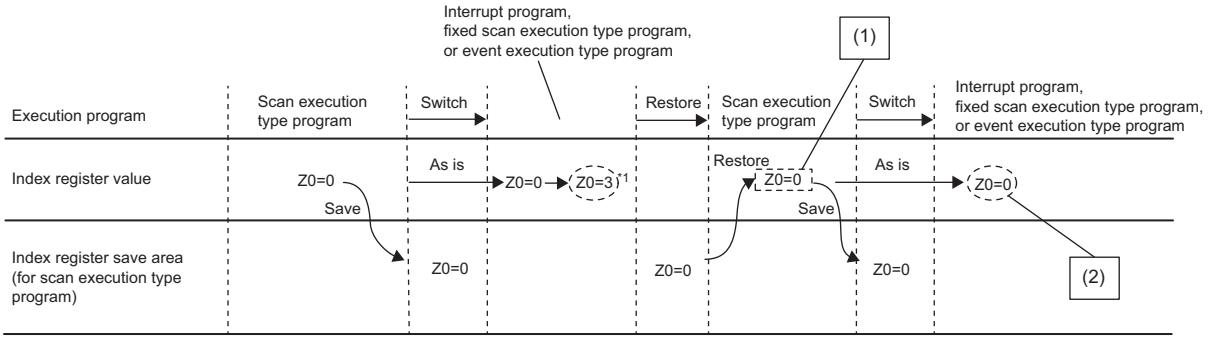
When whether to save/restore the file register (R) block number is set to "Not Saved/Recovered", do not change the file register (R) block number by using the RSET (P) instruction within the interrupt program.
If the number is changed, the execution result (file register switching) will be reflected at the start of the next program. Since this behavior does not guarantee that the result is reflected immediately after restoration from the interrupt program, the block number may not be switched until the start of the next program at maximum.

Saving/restoring of the index register (Z, LZ)

When an interrupt program starts, the value of the index register (Z, LZ) of the running program is saved. When the interrupt program finishes, and the saved value is restored to the running program. Note that when an interrupt program starts, the local index register (Z, LZ) is not switched to the different one. When the local index register (Z, LZ) is used for the interrupt program/fixed scan execution type program/event execution type program which uses occurrence of an interrupt as a trigger, the register which has been used for the previous program is continuously used. Thus, the local index register (Z, LZ) cannot be used independently.

■Save/Recover Setting for Index Register

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Interrupt Settings] ⇨ [Save/Recover Setting for Index Register]

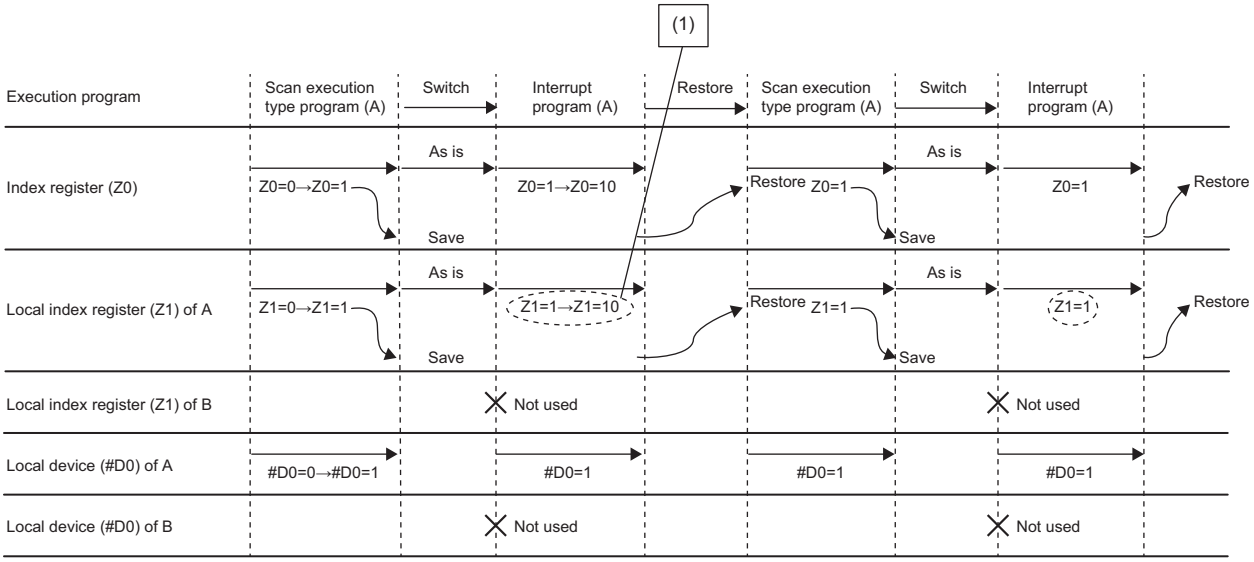


Window

Displayed items

Item	Description	Setting range	Default
Index Register (Z/LZ)	Sets this parameter to change the setting to save/restore the values of the index register and local index register (Z/LZ) when the interrupt program is executed. When the values of the index register and local index register (Z/LZ) are not changed during execution of an interrupt program, enabling "Not Saved/Recovered" can reduce the startup time and the termination time of the interrupt program.	• Not Saved/ Recovered • Save/Recover	Save/Recover

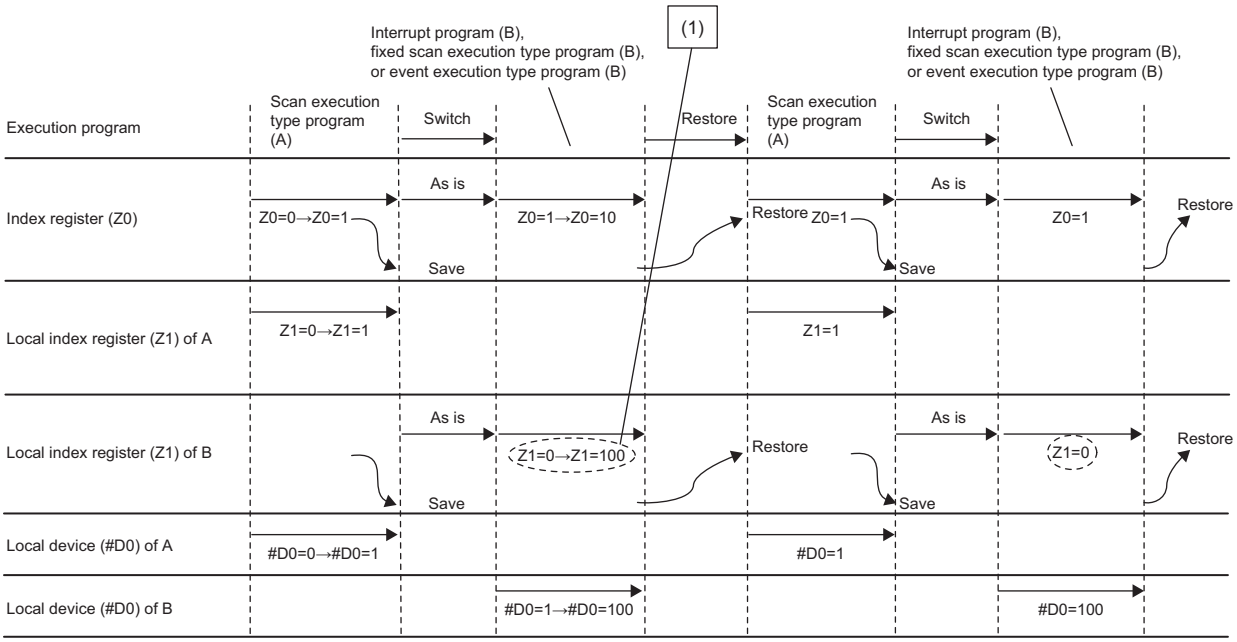
■Operation of saving/restoring of index register



(1) This value can be used as a value specific to the scan execution type program. (Using the value in an interrupt program is not needed to be concerned.)

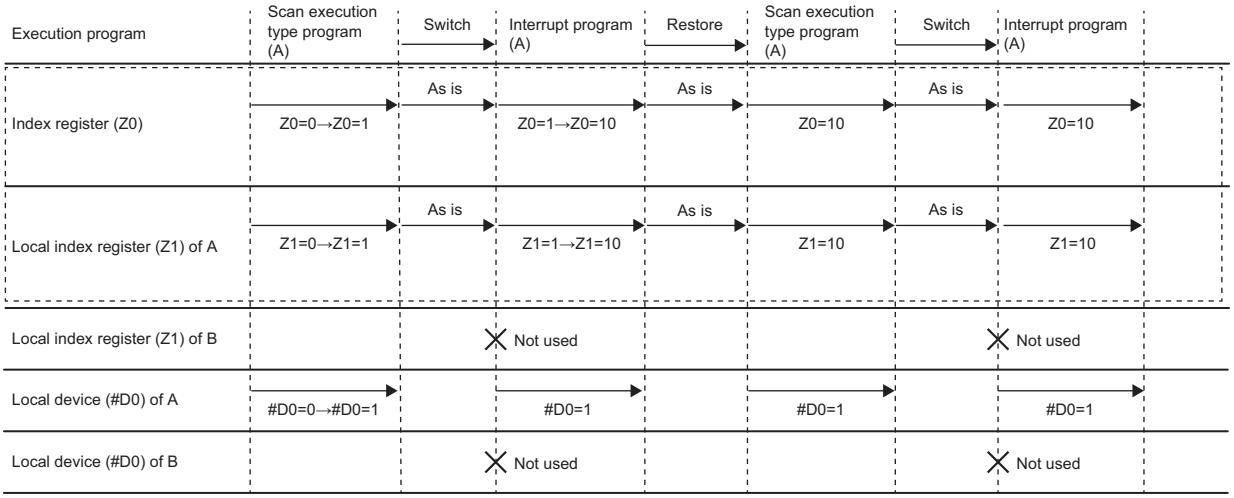
(2) This value can be used only at the moment an interrupt program, fixed scan execution type program, or event execution type program is executed. (The value cannot be used continuously.)

*1 The value of Z0 is changed by the interrupt program, fixed scan execution type program, or event execution type program.



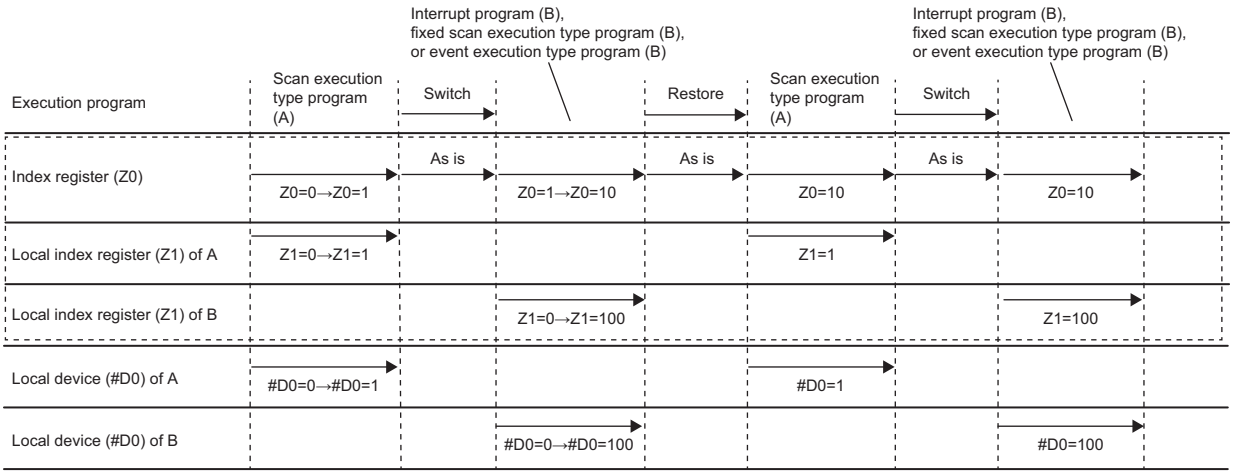
■Operations of the local index register and local device

- Interrupt by a program with the same program number when the index register save/recovery setting is "Save/Recover"



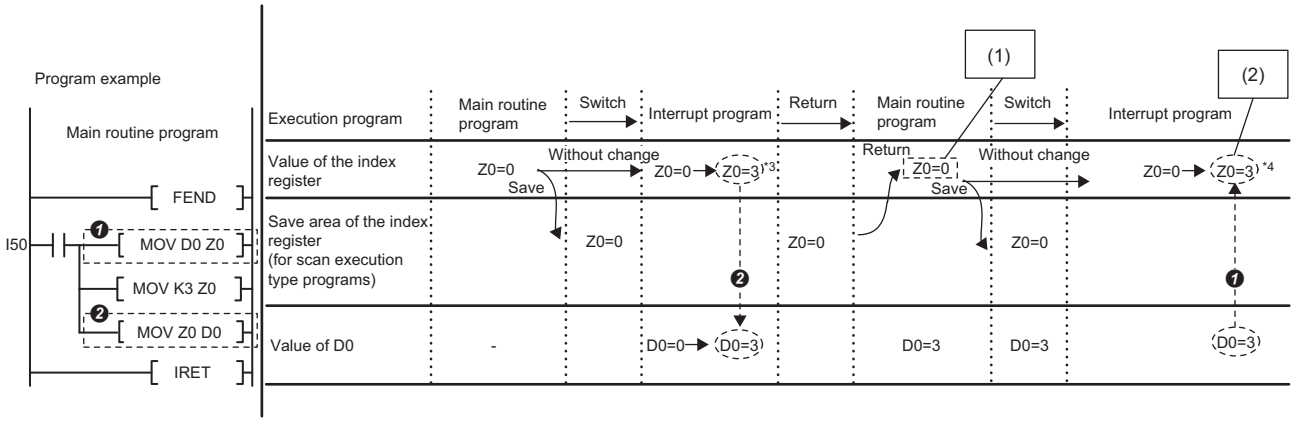
(1) The value of the local index register inherits the value of the scan execution type program (A) before the interrupt program starts, and is discarded when the interrupt program ends.

- Interrupt generated by a program with a different program number when the index register save/recovery setting is "Save/Recover"



(1) The value of the local index register inherits the value of the scan execution type program (B) before the interrupt program starts, and is discarded when the interrupt program ends.

• Interrupt generated by a program with the same program number when the index register save/recovery setting is "Not Saved/Recovered"

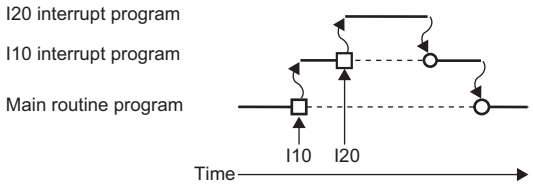


• Interrupt generated by a program with a different program number when the index register save/recovery setting is "Not Saved/Recovered"

Point

If the value of the index register used for the interrupt program is continuously used for the next interrupt program, the value of the index register for the interrupt program must be saved or restored. Create a program to add the MOV instruction and the ZPUSH/ZPOP instruction.
When saving or recovering, the value of the index register is set to 0 in the interrupt program.

*3 A value in Z0 changes at MOV K3 Z0.
*4 Z is zero when the program ❶ and ❷ are not added.



(1) This value can be used as a value specific to the main routine program.
(2) This value can be used as a value specific to the interrupt program. (This value can be used continuously.)

Multiple interrupt

When a new interrupt triggered by another factor occurs during execution of an interrupt program, the running program will be suspended if its priority is lower than that of the new interrupt. A program with higher priority is executed based on the set priority whenever its execution condition is satisfied.
Even if the occurrence timing of multiple interrupts overlaps, the delay from the interrupt occurrence to the completion of the program execution can be reduced.

[Priority]
- I20: High
- I10: Low

If the module access is interrupted and the interrupted program performs module access, the interrupted module access is restarted. Module access of the interrupted program and subsequent operations start after the interrupted module access is completed.

Interrupt priority

If the interrupt priority of a program for which its execution condition has been satisfied is higher than that of the running program, the programs are executed in accordance with their interrupt priority. If the interrupt priority of the new program is the same or lower, it enters the waiting status until the running program finishes.

Interrupt Priority Setting

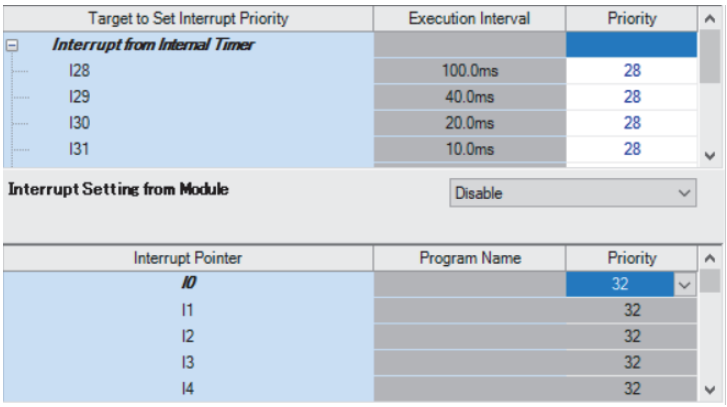
The interrupt priority (1 to 32) can be changed.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Interrupt Settings] ⇨ [Interrupt Priority Setting]

Point

The interrupt priority can also be checked from the CPU parameter program settings for a fixed scan execution type program or an event execution type program (when the trigger type is set to at interrupt occurrence or network communication cycle synchronization).

For details, refer to the following.



☞ Page 244 Program Setting

Operating procedure

"Interrupt Priority Setting" window

"Detailed Setting" window

1. Click "Detailed Setting" on the "Interrupt Priority Setting" window.
2. Change the priority of each interrupt pointer.

Displayed items

Item		Description
Interrupt Priority Setting	Detailed Setting	Sets the target interrupt for which interrupt priority can be set.

The default priority values are shown below.

Interrupt target			Default value
Fixed scan interrupt	Interrupt from Internal Timer	I49	3
		I48	4
		I28 to I31	28
	Fixed scan execution type program	Fixed scan execution	28
	Event execution type program	Network communication cycle synchronization	10
Interrupt from module		I0 to I15, I50 to I1023 (There is no upper limit on the number of pointers that can be set.)	32

Interrupt priority order

The following describes the interrupt priority order.

Priority	Interrupt factor		Pointer
High ↑ ↓ Low	High-speed internal timer interrupt 1		I49
	High-speed internal timer interrupt 2		I48
	Communication period synchronization	Basic period	—
		Normal-speed period	—
		Low-speed period	—
	Internal timer interrupt (I28 to I31)		I31
			I30
			I29
			I28
	Fixed scan execution type program		—
	Interrupt from module (I0 to I15, I50 to I1023)		I0 to I15, I50 to I1023 (ascending order)

Automatic assignment of priority of fixed scan interrupts

Clicking the [Automatic Assignment] button assigns the priority as follows.

- For the network communication cycle synchronization interrupt setting, the values are assigned (fixed) as follows: Basic cycle: 10, medium speed cycle: 11, low speed cycle: 12.
- The fixed cycle interrupt except for the network communication cycle synchronous interrupt is assigned in the order of 1 to 32 (excluding 10 to 12) in order of shortest execution interval.
- The priority of interrupts (I0 to I15, I50 to I1023) from the module does not change.
- When the execution intervals are the same, the same priority is assigned. If there are 32 or more execution intervals, priority 32 is assigned to all execution cycles from the 33rd onward.

Precautions

The precautions for the interrupt program are mentioned below.

Delay in interrupt programs

Completing low-priority interrupt programs may take time if high-priority interrupt programs are executed frequently. Adjust the processing of high-priority interrupt programs to allow execution of low-priority interrupts as necessary.

Devices and labels used in interrupt programs

Do not use the same global devices and labels in multiple interrupt programs. Otherwise, data inconsistency may occur.

Network communication cycle synchronous interrupt priority setting

Set the network communication cycle synchronous interrupt priority as follows. Otherwise, an error occurs.

- Set the interrupt priority value for the network communication cycle synchronous interrupt as basic cycle < medium speed cycle < low speed cycle.
- Do not set the same interrupt priority that has been already assigned to the network communication cycle synchronous interrupt to other fixed scan interrupts and interrupts from the module.

Cycle over

When an interrupt with a higher priority than the network communication cycle synchronous interrupt is set, a cycle over (error code: 1A00H, 3402H) or cycle over warning (event code: 00F08H) may occur when a program is being executed. If such error or event is detected, take the following actions for the programs with a high priority so that the network communication cycle synchronous interrupt can be executed.

- Lower the interrupt priority such that it is lower than that of the network communication cycle synchronous interrupt.
- Shorten the execution time of the program.
- Extend the execution interval for internal timer interrupts and fixed scan execution type programs.

Restrictions on program creation

- The PLS/PLF instruction performs OFF processing in the next scan after the instruction execution. The device that is turned on remains on until the interrupt program starts again and the instruction is executed.
- The timer (T, ST) cannot be used for interrupt programs.

Data inconsistency

Processing of an instruction may be suspended, and the interrupt program may be executed. Accordingly, if the program suspended due to interruption and the interrupt program both use the same data, data may become inconsistent. Therefore, take the following preventive measures.

- Use the DI instruction to disable the interrupt for an instruction that causes inconsistency when interrupted.
- In an interrupt program, before accessing the device shared by overlapping programs, transfer data to another device in batch to use, and then write back to the shared device in batch.
- When using a word device as 32-bit data, use a device number that is a multiple of 2. When using a word device as 64-bit data, use a device number that is a multiple of 4.

If the interrupt accuracy does not increase

The issue may be improved by performing the following.

- Limit each character string used in a program to 32 characters or less in length.
- Decrease the multiplex interrupts.

When the start-up of an interrupt program is delayed

If the execution interval of the interrupt program is short, the start-up of the interrupt program may be delayed when an instruction with a long processing time is executed, or when online change is executed.

When the data logging function is used

- When occurrence of an interrupt is specified as the data collection condition of data logging, set the fixed scan interval of the interrupt program, taking into consideration the processing time added by the data logging function. (☞ Page 1527 Using together with interrupt programs)
- When occurrence of an interrupt is specified as the data collection condition of the logging function, the processing time of the logging function is added and the processing time of the interrupt program increases. For this reason, if an interrupt program that specifies a short interval, such as setting the high-speed internal timer interrupt 1 (I49) to 0.05ms in the fixed scan interval setting, is used and an interrupt occurrence of high-speed internal timer interrupt 1 (I49) is specified as the data collection condition of the logging function, the processing time of the interrupt program will not be within the interval specified in the fixed scan interval setting and a WDT error (error code: 2501H) may occur.

Instructions that use the signal flow

If subroutine programs that use global pointers (P), including instructions that use the signal flow, and FB instances defined in global labels are used from multiple interrupt programs, the corresponding instruction may not work as intended when the same signal flow is used.

Therefore, it is recommended that different subroutines and FB instances be used for each program.

15 OPERATING STATUS OF THE CONTROLLER

The following is a list of the operating statuses of the CPU function part of the controller.

- RUN state
- STOP state
- PAUSE state

15.1 Operating Statuses

The following table shows the operating statuses of the controller, as well as the LED indication and operation processing under each status.

Operating status	LED indication	Operation processing
RUN	PROGRAM RUN LED: On	Executes the program stored in the controller.
STOP	PROGRAM RUN LED: Off	Stops the operation of the program stored in the controller.
PAUSE	PROGRAM RUN LED: Flashing (every 200ms)	Suspends the operation of the program stored in the controller.
INITIALIZE*1	READY LED: Flashing (every 1s)	Performs pre-processing to execute operation of the program in the controller.
RESET	ERROR LED: All LEDs off after flashing	Resets the controller.

*1 After the initial processing, the state changes to the one set by the RUN/STOP/RESET switch.

The following table shows the operation of external output and communication in each operating status of the controller.

○: Operates ×: Does not operate △: Does not operate (can be output by the device test or another method)

Operating status	External output	Communication with external equipment	Communication with a module
RUN	○	○	○
STOP	△	○	○
PAUSE	○	○	○
INITIALIZE	×	×	×
RESET	×	×	×

Point

The operating statuses of the motion function part are the RUN state and STOP state.
Motion control can be executed when the motion function part is in the RUN state.
Use MotionSystem.Cd.SequenceReady to make a request for switching the STOP/RUN state, and use MotionSystem.Md.Ready to monitor the current status. (☞ Page 543 START AND STOP)

15.2 Operation When Operating Status Is Changed

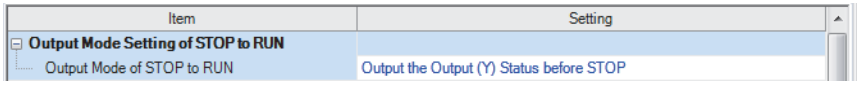
The following table shows the operation when the operating status of the controller is changed.

Operating status of the controller	Each processing of the controller			
	Program	External output	Device/label data	
			Other than Y	Y
STOP → RUN	Executes the initial execution type program or scan execution type program from the start.	Determines the status depending on the setting of "Output Mode Setting of STOP to RUN" in the CPU parameter. (☞ Page 281 Output mode at operating status change (STOP to RUN))	Retains the device/label data status immediately before the RUN state. However, if a device/label initial value has been set and "Device/Label Initial Value Reflection Setting at STOP to RUN" is set to "Enable", this initial value is set.*2 Local devices are cleared if "Device/Label Initial Value Reflection Setting at STOP to RUN" is set to "Enable". (They are not cleared if set to "Disable".)	Determines the status depending on the setting of "Output Mode Setting at STOP to RUN" in the CPU parameter. (☞ Page 281 Output mode at operating status change (STOP to RUN))
RUN → STOP	Executes the program up to the END instruction and then stops.	Saves the output (Y) status immediately before the STOP state, and all points turn off.	Retains the device/label data status immediately before the STOP state.	Saves the output (Y) status immediately before the STOP state, and all points turn off.
RUN → STOP (STOP instruction)	Executes the STOP instruction and then stops.			
RUN → STOP (Stop error)	Suspends the instruction when an error occurs and then stops.	Retains the output (Y) status at STOP.		Retains the output (Y) status at STOP.
RUN → PAUSE*1	Stops after the execution of one scan.	Retains the output (Y) status immediately before the PAUSE state.	Retains the device/label data status immediately before the PAUSE state.	Retains the output (Y) status immediately before the PAUSE state.
PAUSE → RUN*1	Executes the initial execution type program or scan execution type program from the start.	Retains the output (Y) status immediately before the RUN state.	Retains the device/label data status immediately before the RUN state. However, if a device/label initial value has been set and "Device/Label Initial Value Reflection Setting at STOP to RUN" is set to "Enable", this initial value is set.*2 Local devices are cleared if "Device/Label Initial Value Reflection Setting at STOP to RUN" is set to "Enable". (They are not cleared if set to "Disable".)	Retains the output (Y) status immediately before the RUN state.
PAUSE → STOP*1	Operation remains stopped.	Saves the output (Y) status immediately before the STOP state, and all points turn off.	Retains the device/label data status immediately before the STOP state.	Saves the output (Y) status immediately before the STOP state, and all points turn off.

*1 The change of status from RUN to PAUSE, PAUSE to RUN, and PAUSE to STOP of the controller is performed by the remote operation.

*2 For the device/label initial value setting, refer to the following.

☞ Page 426 DEVICE/LABEL INITIAL VALUE SETTINGS



Output mode at operating status change (STOP to RUN)

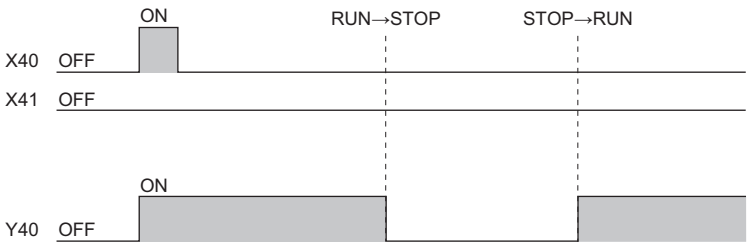
When the operating status changes from RUN to STOP, for example, the controller internally stores the status of the outputs (Y) to turn them all off.

Set the mode in "Output Mode Setting of STOP to RUN".

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Operation Related Setting] ⇨ [Output Mode Setting of STOP to RUN]

Window

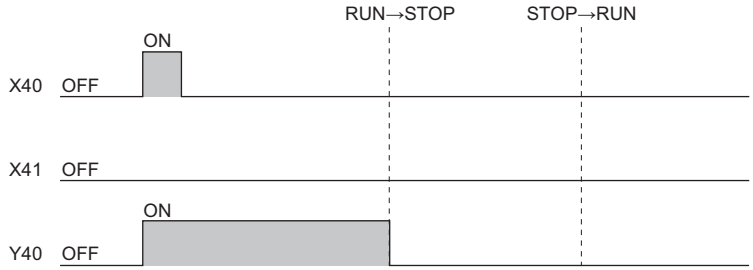
Displayed items



Item	Description	Setting range	Default
Output Mode of STOP to RUN	Set the operation of the output (Y) when the operating status is changed from STOP to RUN.	• Output the Output (Y) Status before STOP • Clear (Output is 1 scan later) the Output (Y)	Output the Output (Y) Status before STOP

Operation when the operating status is changed from STOP to RUN

Select whether or not to resume from the previous output status when the operating status of the controller changes from STOP to RUN by using a holding circuit.

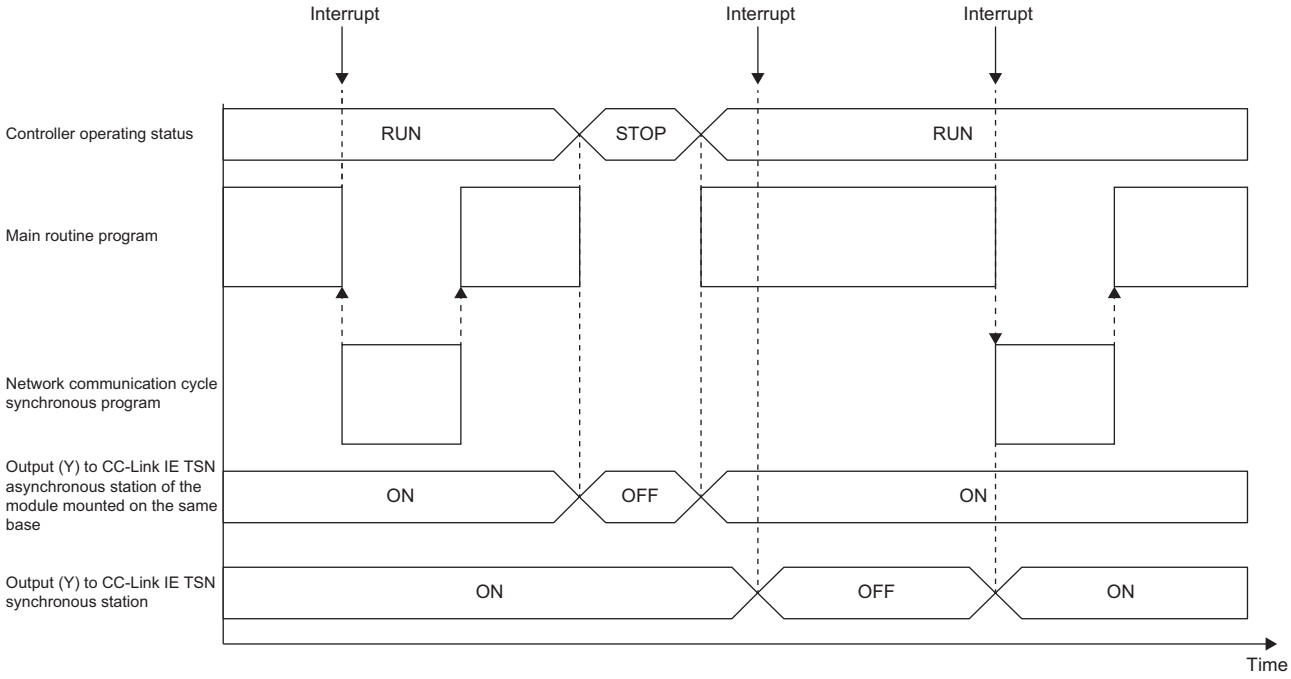


■Output the Output (Y) Status before STOP

The program operation is resumed after outputting the output (Y) status immediately before the operating status of the controller is changed to the STOP state. If the output (Y) is forcibly turned on in the STOP state, the status prior to the STOP state is output. If the output (Y) was off before entering the STOP state, the status when it was on is not retained. (In the following figure, X40 represents the start button, X41 represents the stop button, and Y40 represents an output.)

■Clear (Output is 1 scan later) the Output (Y)

All outputs are turned off, and the output (Y) is output after the program operations are executed. If the output (Y) is forcibly turned on when the operating state is STOP, the ON state is retained. (In the following figure, X40 represents the start button, X41 represents the stop button, and Y40 represents an output.)



Precautions

- The following table lists the output when the STOP state changes to the RUN state after the output (Y) is forcibly turned on while the controller is in the STOP state.

Setting item	Output when the operating status is changed from STOP to RUN
Output the Output (Y) Status before STOP	Outputs the state before STOP. If the output (Y) was off before entering STOP, the status when it was on is not retained.
Clear (Output is 1 scan later) the Output (Y)	The on state is held.

- Output is performed when the output (Y) is assigned as the refresh target device of the link device assigned to the synchronization station of the CC-Link IE TSN function, and when the STOP state is changed to the RUN state immediately before the network communication cycle synchronous interrupt program execution for the first time after being changed to the RUN state. The following shows the case when "Output Mode of STOP to RUN" is set to "Output the Output (Y) Status before STOP".

15.3 Operation during a Momentary Power Failure

When an input power supply voltage supplied to the power supply module falls below the specified range, a momentary power failure is detected and the following operation is performed.

Momentary power failure not exceeding the allowable momentary power failure time

If a momentary power failure occurs, the event history is registered and operation processing continues, but the storage of values from the input module stops. However, the measurement of the output and the timer device continues.
Also, the scan time does not change due to momentary power failure.

■When recovered from a momentary power failure

After recovering from a momentary power failure, the stopped operation of storing the value to the input (X) resumes.

Momentary power failure exceeding the allowable momentary power failure time

This case results in initial start, and the same operation processing as when the controller is powered on or reset, or when remote reset is performed.

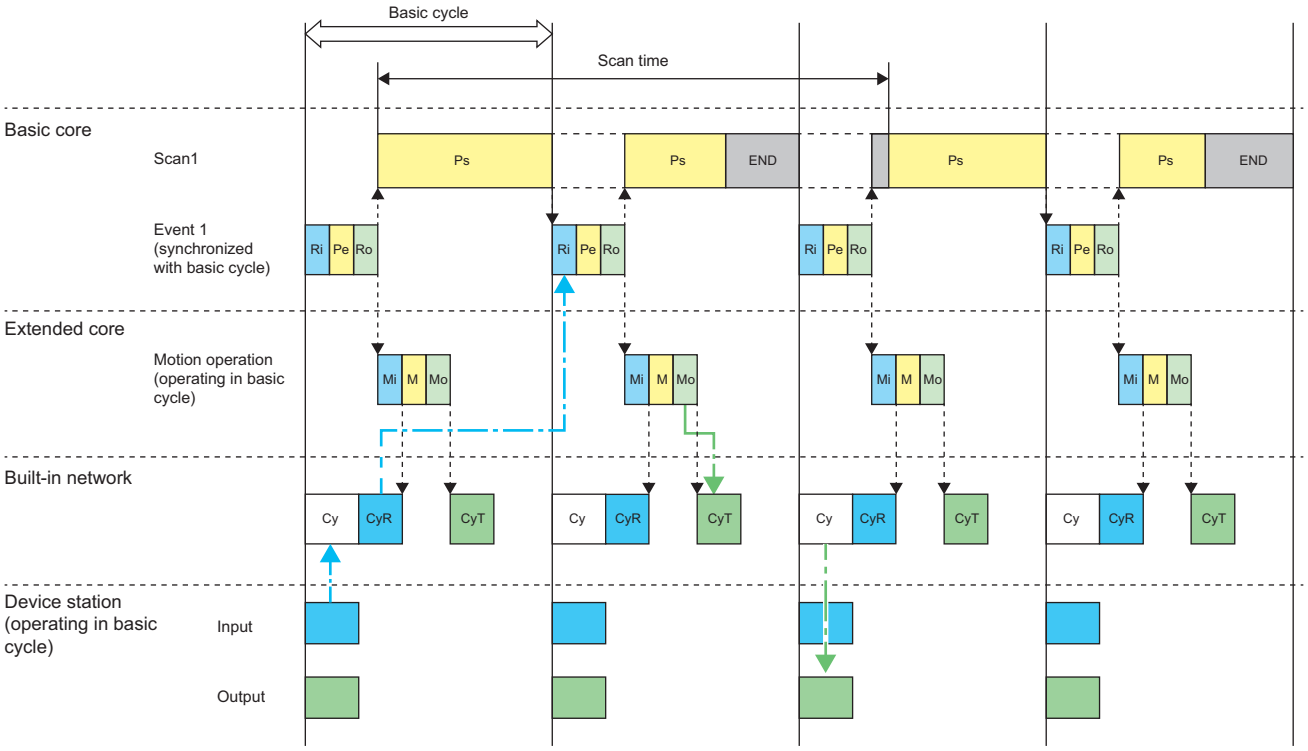
15.4 Operation When an Error Occurs

If the controller detects an error, the self-diagnostic function stores error information in the special relay/special register areas.
For details on the self-diagnosis function, refer to the following.
☞ Page 1745 Self-diagnostic function
There are two types of errors: continuation errors and stop errors. Some errors can be set to either a stop error or a continuation error with the parameter settings.
For error details and error types (stop error or continuation error), refer to the following.
☞ Page 1776 Error Code System
The operation when an error occurs is shown below.

Stop error

If the controller detects an error, the self-diagnostic function stores error information in the special relay/special register areas.
The operation stops and enters the STOP state.
Communication with the controller is possible even if the controller has a stop error.
In addition, the external output of the module follows the combination of the controller operation settings for error detection and the output mode when module parameter error occurs for the module managed by the controller. For details, refer to the following.
☞ Page 1749 System operation

Continuation error



If the controller detects an error, the self-diagnostic function stores error information in the special relay/special register areas.
The operation status is held and the operation is continued.
Continuation errors can be cleared. If the error is cleared and the system is restored, the state returns to that before the error occurred. For details on clearing errors, refer to the following.
☞ Page 1751 Error clear

16 CC-Link IE TSN COMMUNICATION CYCLE AND MOTION OPERATION

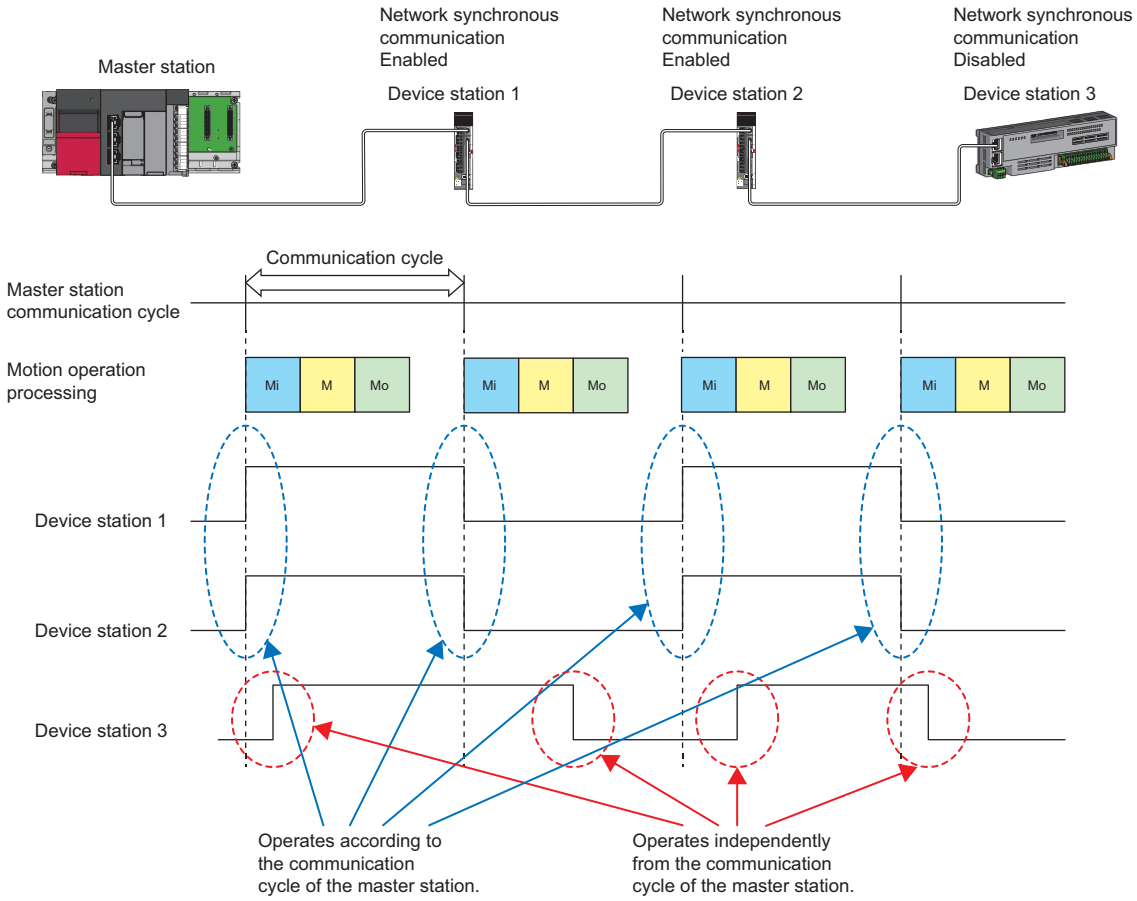
Programs can be executed in synchronization with the communication cycle of CC-Link IE TSN. This allows motion control to be executed without being affected by scan time fluctuations.

Ex.

When executing a motion control program (Event1) at each basic cycle and receiving/sending input/output data from/to the device station

Category	Symbol	Item	Description
Basic core	Ps	Scan1 (scan execution type) program execution	Scan execution type Scan1 is executed on the basic core. Input/output refresh is performed in the END processing after program execution.
	END	END processing (input/output refresh of asynchronous station)	
	Ri	Input refresh of synchronous station (basic cycle)	Event execution type (network communication cycle synchronization) Event1 is executed in synchronization with the basic cycle. In network communication cycle synchronous interrupt programs, input refresh (Ri) is performed before program execution and output refresh (Ro) is performed after program execution. Refresh is performed for device stations whose "Network Synchronous Communication" is set to "Synchronous". (☞ Page 289 Network synchronous communication setting)
	Pe	Program execution of Event1 (synchronized with basic cycle)	
	Ro	Output refresh of synchronous station (basic cycle)	
Extended core	Mi	Input processing of motion operation (basic cycle)	After completion of output refresh (Ro) of the synchronous station, the motion operation of the motion control FB in Event1 is executed by the extended core.
	M	Operation processing of motion operation (basic cycle)	
	Mo	Output processing of motion operation (basic cycle)	
Built-in network	Cy	Cyclic transmission	Cyclic receive processing (CyR) is executed after completion of cyclic transmission (Cy), and cyclic send processing (CyT) is executed after completion of output processing of motion operation (basic cycle) (Mo).
	CyR	Cyclic receive processing	
	CyT	Cyclic send processing	

Point



In the motion system, operation processing related to the motion control is performed in the fixed cycle (motion operation cycle).
The shorter the motion operation cycle, the higher the accuracy and responsiveness of motion operation. For details on the motion operation cycle, refer to the following.
☞ Page 522 OPERATION CYCLE

16.1 Network Synchronous Communication

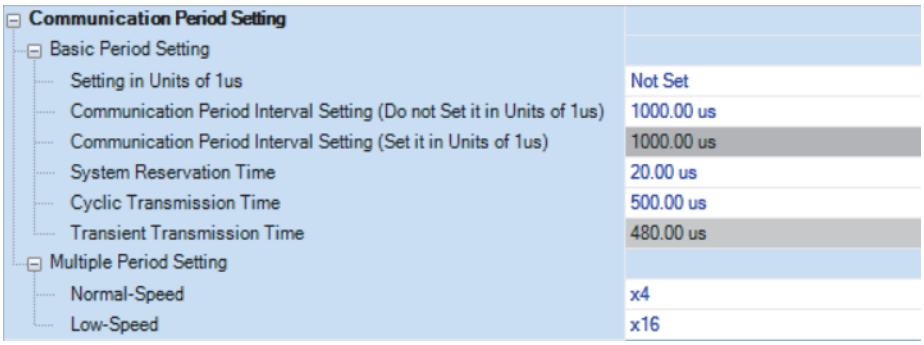
The control cycle of a device station is synchronized according to the communication cycle of the master station.

Point

The following device stations can also be connected: device stations not supporting the CC-Link IE TSN network synchronous communication, or device stations in which the network synchronous communication setting is not set. However, the stations cannot be synchronized with the motion operation of the controller. For the support status of network synchronous communication of each device, refer to the manual of the relevant device.

Mi: Input processing of motion operation (basic cycle)
M: Operation processing of motion operation (basic cycle)
Mo: Output processing of motion operation (basic cycle)

Point



In addition to the Network Communication Cycle Synchronization accuracy, each device station performs the input or output processing after the response time of each device station. (The Network Communication Cycle Synchronization accuracy is the difference between the time at which the device station recognizes the synchronization point and the time of the synchronization point.)
Therefore, the actual time for external output will deviate up to the following amount.
Network communication cycle synchronization accuracy (1000ns) + Device station response time (Tres)
For details on the device station response time (Tres), refer to the manual for the device station used.

Setting method

Set "Basic Period Setting" and "Network Synchronous Communication".

■Basic period setting

[Module Parameter (CC-Link IE TSN)] ⇨ [Basic Settings] ⇨ [Communication Period Setting]

Item		Description	Setting range
Basic Period Setting	Setting in Units of 1μs	Select whether to set the basic cycle in increments of 1μs.	• Set • Not Set (default)
	Communication Period Interval Setting (Do not Set it in Units of 1μs)*1	Select the communication cycle.	• 125.00μs • 250.00μs • 500.00μs • 1000.00μs • 1500.00μs • 2000.00μs (default) • 2500.00μs • 3000.00μs • 3500.00μs • 4000.00μs • 4500.00μs • 5000.00μs • 5500.00μs • 6000.00μs • 6500.00μs • 7000.00μs • 7500.00μs • 8000.00μs
	Communication Period Interval Setting (Set it in Units of 1μs)*1	Input the setting range of the communication cycle interval.	125.00μs to 10000.00μs (in increments of 1μs) (Default: 2000.00μs)
	System Reservation Time	Necessary time for the system to guarantee the communication cycle interval When using a CC-Link IE TSN Class B/A device with a communication speed of 100Mbps in the basic cycle, select 200μs.	• 20.00μs (default) • 200.00μs
	Cyclic Transmission Time*1	Set the time to be allocated to cyclic transmission in communication cycle intervals.	5.00μs to 9966.00μs (in increments of 1μs) (Default: 1000.00μs)
	Transient Transmission Time	The value displayed is the "Basic Period Setting" value minus the "Cyclic Transmission Time" and "System Reservation Time". Secure a transient transmission time of 14.00μs or more.	14.00μs to 9975.00μs (in increments of 1μs) (Default: 980.00μs)
Multiple Period Setting		☞ Page 293 Multiple period setting	

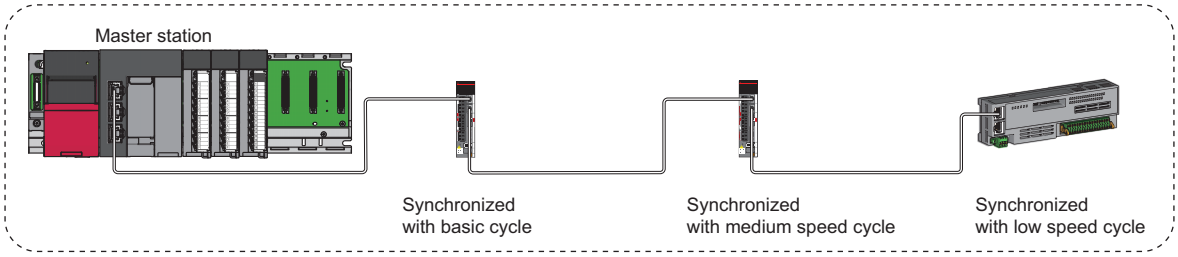
*1 For "Communication Period Interval Setting" and "Cyclic Transmission Time", refer to the following.
☞ Page 306 Communication Cycle Adjustment,Page 2116 Shortening method of the communication cycle interval and cyclic transmission time

Point

- When an industrial switch (CC-Link IE TSN Class B certified) is used, set the timeslot information from the setting values in "Basic Period Setting". The timeslot information can be checked with the buffer memory. (☞ Page 2063 Timeslot information)
- Set "Communication Period Setting" according to the communication cycle supported by the device stations. Even if "Communication Period Setting" in the device station is set to "Normal-speed" or "Low-speed", set the communication cycle value supported by the device station to the value in "Communication Period Interval Setting" of "Basic Period Setting".

■Network synchronous communication setting

Set each device station in the "CC-Link IE TSN Configuration" window as shown below.



Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [Module Parameter (Port 1/2: CC-Link IE TSN)] ⇨ [Module Parameter (CC-Link IE TSN)] ⇨ [Basic Settings] ⇨ [Network Configuration Settings]

	No.	Model Name	Subnet Mask	Default Gateway	Reserved/Error Invalid Station	Network Synchronous Communication	Communication Period Setting
	0	Host Station					
	1	MR-J5-G			No Setting	Synchronous	Basic Period

Simple display	Detailed display	Description	Setting range
Network Synchronous Communication		Sets whether to synchronize each device station with the network synchronous communication.	• Synchronous • Asynchronous (Default: Varies depending on the set module)

Synchronizable range

The control timing of the master station and device stations can be synchronized within the following range.

Watchdog counter

The watchdog counter is a function used to monitor for normal cyclic transmission between stations on CC-Link IE TSN. Using the watchdog counter, the master station and a device station mutually monitor the data to be updated every communication cycle; the master station monitors data received from a device station and a device station monitors data received from the master station.

Point

Whether the device station is using the watchdog counter during a data link with the master station can be checked with 'Watchdog counter operation status of each station' (SW01D0 to SW01D7).

■Operation

If the data received from the device station at the master station is not updated every communication cycle, a synchronization watchdog counter error (error code 125AH or 1A40H) will occur. If a watchdog counter error occurs, the data of that station will not be received, even after the watchdog counter returns to the normal state. For details on the restart conditions for data reception, refer to the following.

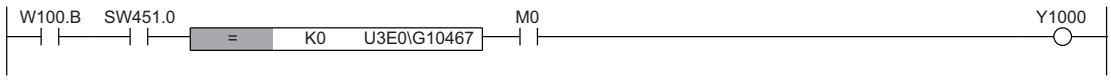
☞ Page 240 Checking received data using the watchdog counter

If the watchdog counter initialization processing of the device station fails, a synchronization watchdog counter initialization error (error code 1871H) will occur.

■Setting method

To enable watchdog counter update and check, set the master station's "Network Synchronous Communication" to "Synchronous". (If the master station's "Network Synchronous Communication" is set to "Asynchronous", watchdog counter update and check will be disabled.)

However, even when the master station's "Network Synchronous Communication" is set to "Synchronous", if the device station does not have a watchdog counter, watchdog counter update and check will be disabled.



The settings may be required depending on the device station used. (📖Manual for the device station used)

Network communication cycle synchronization programming

The following example shows a program that controls the on and off of a remote output module whose station number is 17 and module number is 17.

The program is created as an event execution type program with "Trigger Type" set to "Network Communication Period Synchronization".

This program turns on Y0 of station number 17 when the execution instruction (M0) is on.

W100.B: Station number 17 remote READY
SW451.0: Station number 17 synchronous operating status information
U3E0\G10467: Module number 17 synchronous communication received data transfer status
M0: Execution instruction
Y1000: Station number 17 Y0

The following shows the network configuration settings of the program example.

	No.	Model Name	STA#	Station Type	Network Label	RX Setting			RY Setting			RWr Setting			RWw Setting		
						Points	Start	End	Points	Start	End	Points	Start	End	Points	Start	End
	17	NZ2GN2S1-32T	17	Remote Station	☐	32	0000	001F	32	0000	001F	4	0000	0003	4	0000	0003

Network Synchronous Communication: Synchronous
CC-Link IE TSN Class: CC-Link IE TSN Class B

The following shows the refresh settings of the program example.

No.	Link Side					CPU Side				
	Device Name	Points	Start	End		Target	Device Name	Points	Start	End
1	RWr	4	00000	00003	⇔	Specify Devi	W	4	00010	00013
2	RY	32	00000	0001F	⇔	Specify Devi	Y	32	01000	0101F

Associated devices and buffer memory

The following table lists the associated link special register areas.

No.	Name	Reference
SW01E9	Network synchronous communication function cycle over detection count	Page 2017 List of link special register (SW)
SW0440 to SW044F*1	Information of CC-Link IE TSN Network synchronous communication function of each station (station number: 1 to 253)	
SW0450 to SW045F*2	Synchronous/asynchronous operating status information of each station (station number: 1 to 253)	

*1 If the station number of the device station to be connected is within 120, SW01C0 to SW01C7 (CC-Link IE TSN network synchronous communication function information (station number 1 to 120) for each station) can also be used.

*2 If the station number of the device station to be connected is within 120, SW01C8 to SW01CF (synchronous/asynchronous operating status information (station number 1 to 120) for each station) can also be used.

The following table lists the associated link special relay areas.

No.	Name	Reference
SB01E1	Setting status of CC-Link IE TSN Network synchronous communication function	Page 2013 List of link special relay (SB)
SB01E9	Network synchronous communication function cycle over occurrence flag	

The following table lists the associated buffer memory area.

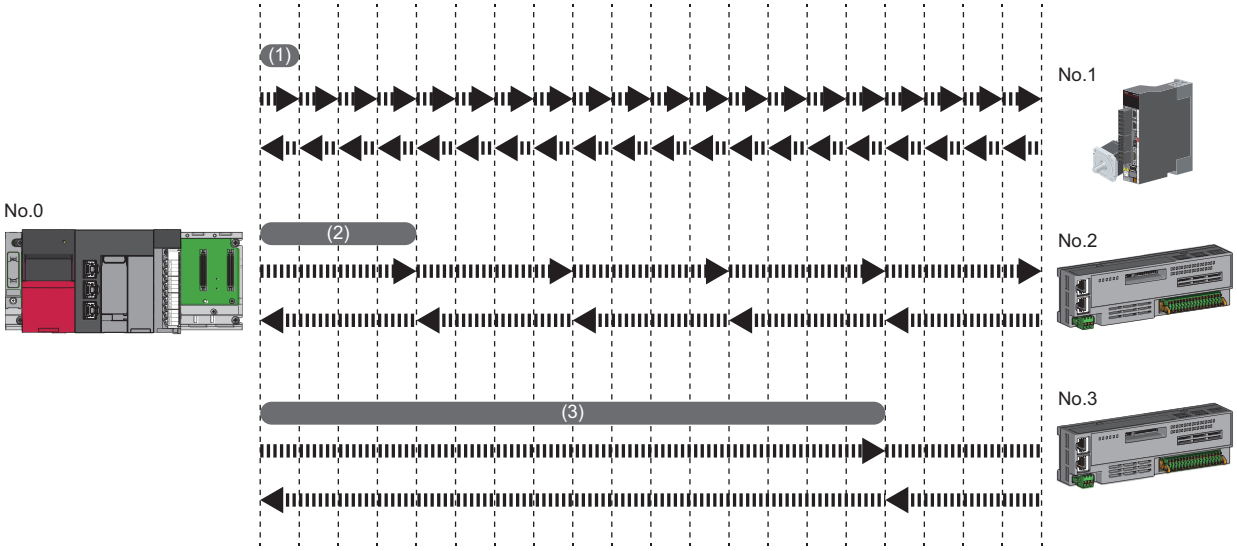
No.	Name	Reference
U3E0\G10451 to G10706	Synchronous communication received data transfer status (Module No.1 to 256)*3	Page 2060 Synchronous communication received data transfer status (Module No.1) to Synchronous communication received data transfer status (Module No.256)

*3 This buffer memory area will be used as interlock when the transfer stops for the synchronous communication received data of the station corresponding to the watchdog counter.

Restrictions

- Network synchronous communication is not possible with CC-Link IE TSN Class A devices.
- For the number of connectable devices, connection order, and compatible devices, refer to the following.

☞ Page 171 Structure with CC-Link IE TSN Class B Devices Only
☞ Page 178 Structure with CC-Link IE TSN Class B/A Devices



- Network synchronous communication is not possible if the communication is relayed via another network.
- When a switching hub is used, refer to the following and use a compatible product.

☞ Page 63 Industrial switch

- Network synchronous communication is possible when "Network Topology" is set to "Line/Star".

Communication cycle coexistence

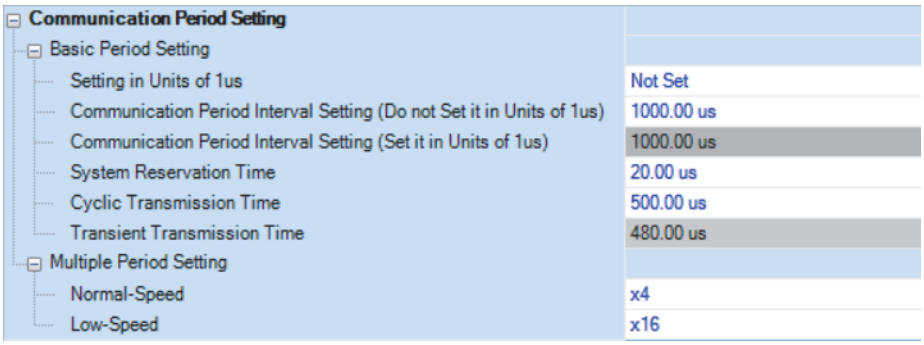
If devices with different communication cycles coexist, cyclic data communication can be performed at the cycle of each device. High-speed communication devices and low-speed communication devices can be combined in a single network without affecting the high-speed communication devices with low-speed communication devices.
The master station can communicate with device stations by using three communication cycles consisting of the basic cycle under "Basic Period Setting", as well as "Normal-Speed" and "Low-Speed" under "Multiple Period Setting".

(1) Basic cycle
(2) Medium speed
(3) Low speed

The time for each communication cycle is the total time of cyclic transmission, transient transmission, and system reservation time.
Even if device stations with different communication cycles are connected to a network, a device station with a high-speed communication cycle is not affected by a device station with a low speed.

Point

- By using the motion operation cycle, the first, second, and third operation cycles can be set. The first motion operation cycle synchronizes with the basic cycle of the network. The second motion operation cycle synchronizes with the medium speed cycle of the network, and the third motion operation cycle synchronizes with the low speed cycle of the network.
- A motion operation cycle can include a mix of up to three cycles. A system with many axes can be controlled in divided manner by operating a specific axis at a fast operation cycle and operating other axes at a low speed operation cycle.



For details on the mixed use of operation cycles for motion operation, refer to the following.
☞ Page 535 Operation Cycle Coexistence

Setting method

Set "Multiple Period Setting" and "Communication Period Setting".

■Multiple period setting

[Module Parameter (CC-Link IE TSN)] ⇨ [Basic Settings] ⇨ [Communication Period Setting]

Item		Description	Setting range
Basic Period Setting		☞ Page 287 Basic period setting	
Multiple Period Setting	Normal-Speed	Select a "Normal-Speed" multiplying factor for a basic cycle. Setting is not required and can be left as "×4".	×4 (default)
	Low-Speed	Select the "Low-Speed" multiplying factor for a basic cycle. Select a value greater than "×16" in the following cases. • The communication cycle interval needs to be shortened for CC-Link IE TSN Class B devices. • The event of invalid communication cycle interval setting and low-speed multiplying factor (error code: 3A60H or 1854H) is detected.	• ×16 (default) • ×32 • ×64 • ×128

Point

- When an industrial switch (CC-Link IE TSN Class B certified) is used, set the timeslot information from the setting values in "Basic Period Setting". The timeslot information can be checked with the buffer memory. (☞ Page 2063 Timeslot information)

Precautions

When the device station used is a CC-Link IE TSN Class A device whose "Communication Period Setting" is set to "Low-Speed", depending on the maximum response time during the time-managed polling method, the "Communication Period Interval Setting" value, and the "Low-Speed" multiplying factor of the device station, send/receive of the cyclic data cannot be guaranteed within the low-speed cycle.

At this time, the event of invalid communication cycle interval setting and low-speed multiplying factor (error code: 3A60H or 1854H) will be detected.

Then, calculation values that guarantee send/receive of the cyclic data within the low-speed cycle will be stored in the following buffer memory addresses. Set values that are equal to or greater than the stored values.

- Multiple cycle setting (low speed) (Un\G1277442)
- Communication cycle interval (calculation value) (Un\G1277443)

■Communication Period Setting

Configure the setting in the "CC-Link IE TSN Configuration" window of the master station according to the communication cycles supported by the device station.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [Module Parameter (Port 1/2: CC-Link IE TSN)] ⇨ [Module Parameter (CC-Link IE TSN)] ⇨ [Basic Settings] ⇨ [Network Configuration Settings]

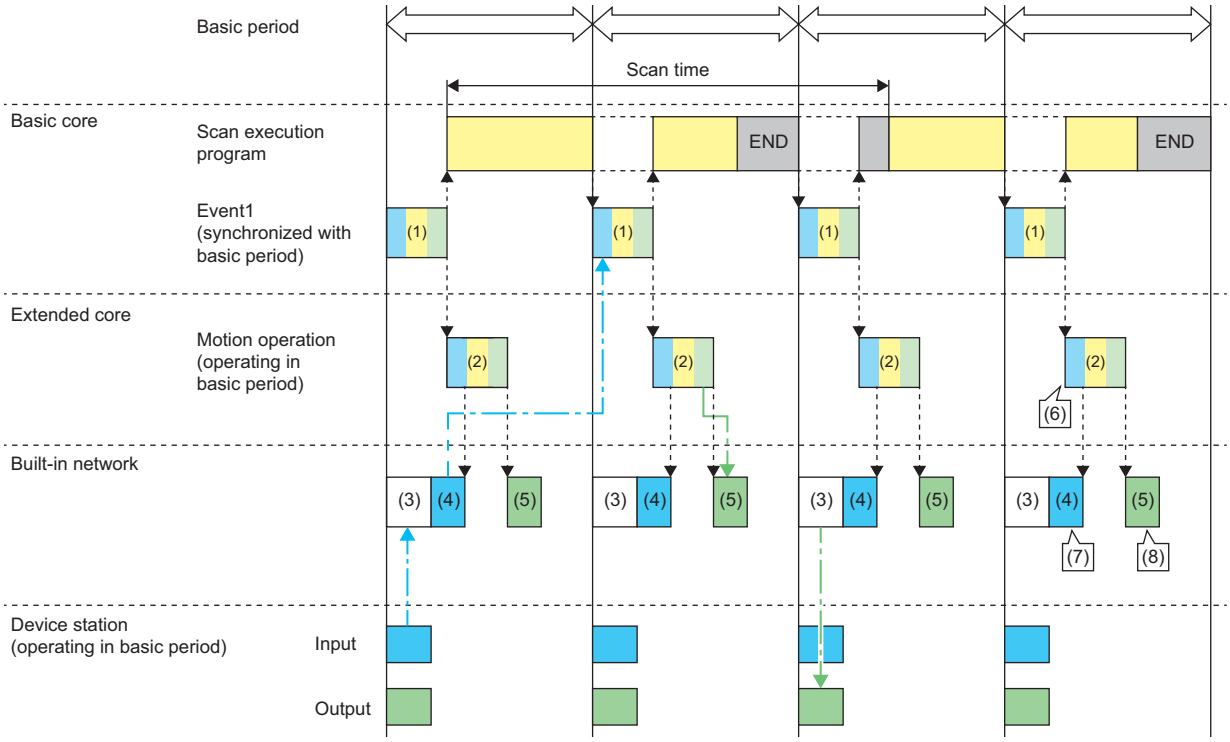
	No.	Model Name	Subnet Mask	Default Gateway	Reserved/Error Invalid Station	Network Synchronous Communication	Communication Period Setting
	0	Host Station					
	1	MR-J5-G			No Setting	Synchronous	Basic Period

Simple display	Detailed display	Description	Setting range
Communication Period Setting		When multiple communication cycles are set, set the cycle of each device station.	• Basic Period (default) • Normal-Speed • Low-Speed

Point

After setting, refer to the following and adjust the communication cycle setting.

☞ Page 306 Communication Cycle Adjustment



16.2 Program Execution Synchronized with Communication Cycle

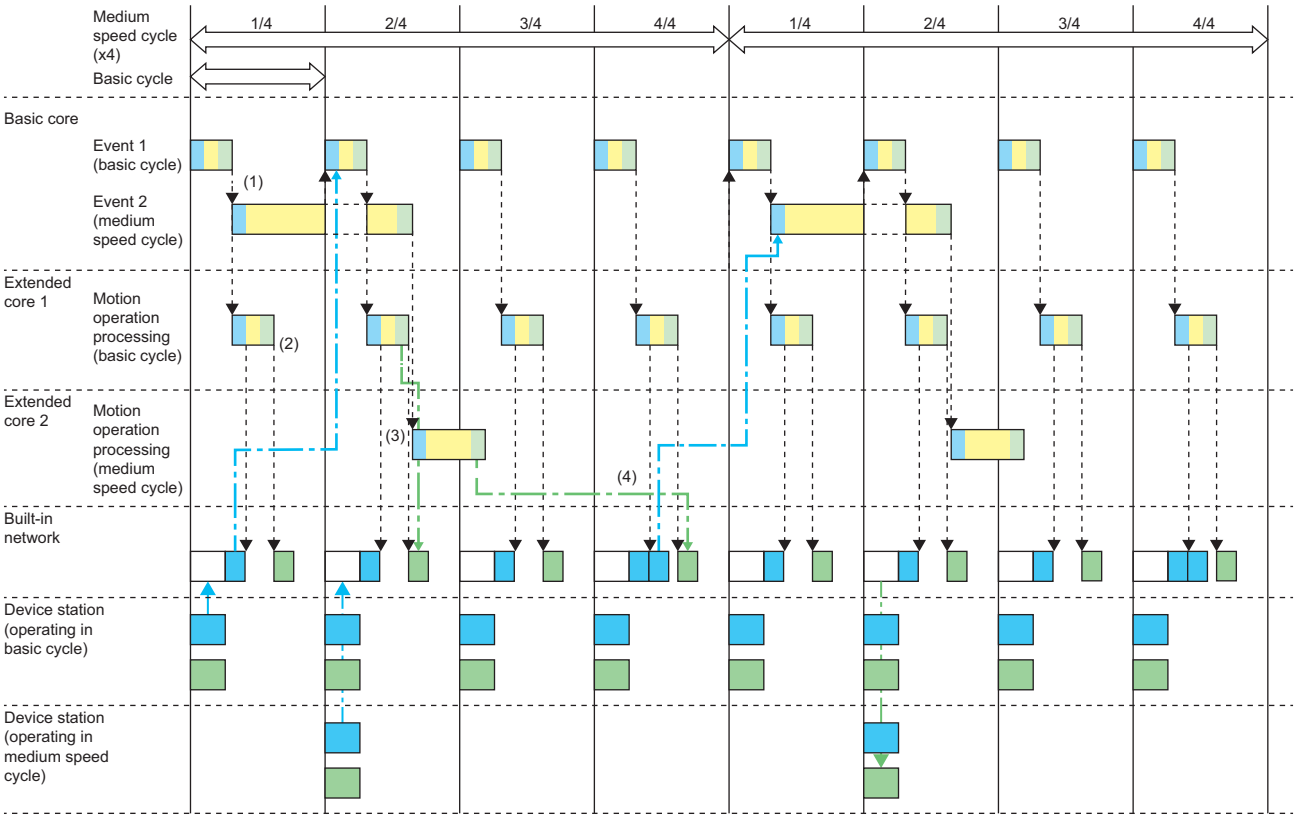
The event execution type program is executed in synchronization with the network communication cycle.
The network communication cycle synchronous interrupt program performs refresh before and after executing the program that synchronizes with each communication cycle (basic cycle/normal-speed/low-speed). At that time, refresh is performed for device stations whose "Network Synchronous Communication" in the "CC-Link IE TSN Configuration" window is set to "Synchronous".
In addition, the motion operation processing that is running in each communication cycle is executed after refresh is performed for each communication cycle. Cyclic send processing is executed after completion of motion operation processing.

Point

- The "Network Communication Period Synchronization" can be selected from "Synchronize with Basic Period", "Synchronize with Normal-Speed", and "Synchronize with Low-Speed".
- Only one program with the same execution cycle can be created.

For a single cycle

(1) After input refresh of the synchronous station (basic cycle), the Event1 program (synchronized with the basic cycle) is executed, and then output refresh of the synchronous station is executed.
(2) After the input processing of the motion operation (basic cycle) is completed, the motion operation processing and output processing are executed in that order.
(3) The cyclic transmission is executed.
(4) Cyclic receive processing is executed.
(5) Cyclic send processing is executed.
(6) After completion of output refresh of the synchronous station, motion operation is executed.
(7) After completion of the cyclic transmission, the cyclic receive processing is executed.
(8) After the motion operation output processing is completed, the cyclic send processing is executed.



Point

- After the input/output processing (2) of motion operation (basic cycle) is completed, the cyclic send processing (5) is executed. If the motion operation (basic cycle) is not performed, after the output refresh (1) of the synchronous station (basic cycle) is completed before and after program execution, the cyclic send processing (5) is performed.
- Adjust the network communication cycle so that cyclic transmission processing (5) can be completed within the communication cycle. (☞ Page 306 Communication Cycle Adjustment)

For multiple cycles (execution on the basic core)

The following shows an example of "Synchronize with Basic Period" and "Synchronize with Normal-Speed".

Execute Order	Program Name	Execution Type		Interrupt Priority
		Type	Detailed Setting Information	
1	Scan	Scan		
2	Event1	Event	Network Communication Period Synchronization:Synchronize with Basic Period	10
3	Event2	Event	Network Communication Period Synchronization:Synchronize with Normal-Speed	11

(1) The programs are executed according to their priority. After input refresh of the synchronous station (basic cycle), the Event1 (basic cycle) program and output refresh of the synchronous station (basic cycle) are executed in that order. Then, the basic core executes input refresh of the synchronous station (medium speed cycle), Event2 (medium speed cycle), and output refresh of the synchronous station (medium speed cycle).

(2) After the output processing of motion operation (basic cycle) is completed, the cyclic send processing is performed.

(3) After output refresh is completed for the synchronous station (medium speed cycle), motion operation (medium speed cycle) input processing, motion operation, and output processing are executed.

(4) After the output processing of motion operation (medium speed cycle) is completed and after the output processing of motion operation (basic cycle) in the 4/4 cycle is completed, cyclic send processing is executed.

Point

- For device stations that are refreshed in synchronization with the network communication cycle synchronous interrupt program, set "Network Synchronous Communication" in the "CC-Link IE TSN Configuration" window to "Synchronous". Device stations set to "Asynchronous" are refreshed in the END processing.
- Priority can be set for network communication cycle synchronous interrupt programs. Set the priority so that programs with a short communication cycle have higher priority. (☞ Page 275 Interrupt Priority Setting)
- Adjust the network communication cycle so that the output processing of motion operation (normal speed/low speed) can be completed by the completion of the output processing of motion operation (basic cycle) in the cycle (N/N cycle) before the beginning of each cycle. (☞ Page 306 Communication Cycle Adjustment)

Operation when the conditions are satisfied

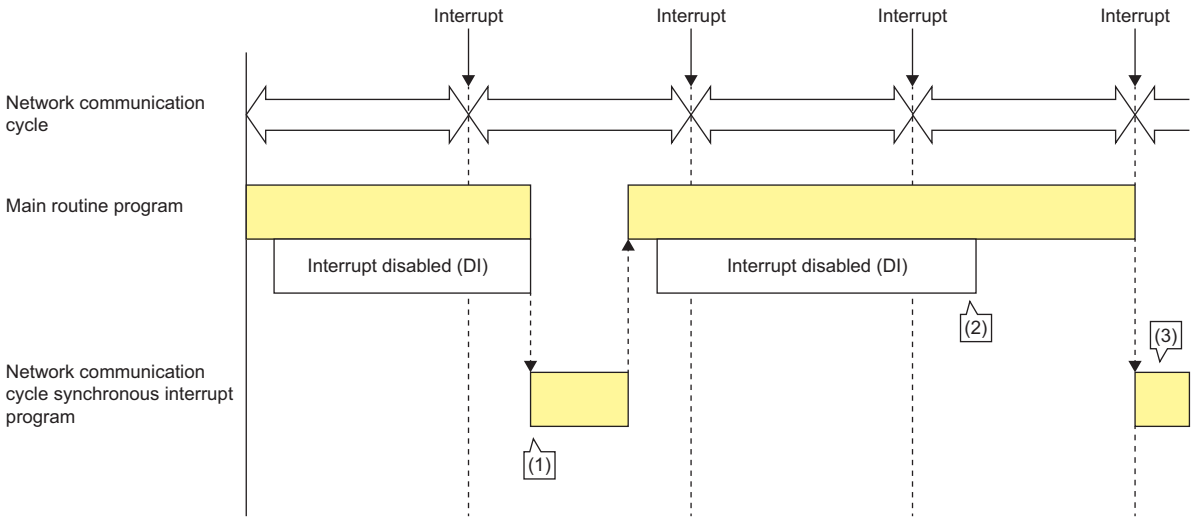
The processing shown below is performed when the network communication cycle synchronous interrupt program starts.

■If an interrupt factor occurs during link refresh

The link refresh is suspended and the network communication cycle synchronous interrupt program is executed. The same operation is performed as the operation of the fixed scan execution type program. (☞ Page 249 If an interrupt factor occurs during link refresh)

■If an interrupt factor occurs during the waiting time after END processing in constant scan execution

The network communication cycle synchronous interrupt program is executed. The same operation is performed as the operation of the fixed scan execution type program. (☞ Page 250 If an interrupt factor occurs during the waiting time after END processing in constant scan execution)



■If another interrupt occurs while the network communication cycle synchronous interrupt program is being executed

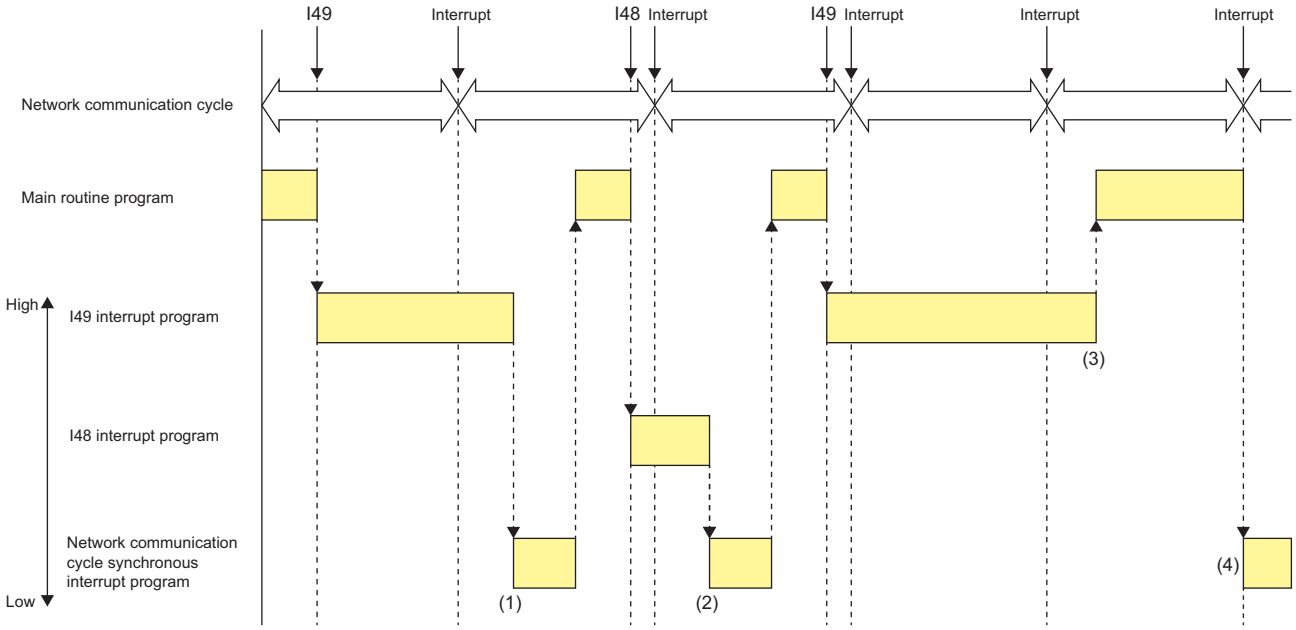
The operation is performed according to the interrupt priority. (☞ Page 274 Multiple interrupt)

Operation details

■If an interrupt factor occurs while interrupt is disabled (DI)

The operation differs depending on whether or not interrupts are enabled by the next cycle.

(1) If interrupts are enabled before the next cycle, the network communication cycle synchronous interrupt program will be executed when interrupts are enabled.



(2) If the interrupt disabled state exceeds the next cycle (2nd cycle), the network communication cycle synchronous interrupt program will not be executed even in the interrupt enabled state. If the network communication cycle synchronous interrupt program cannot be executed due to this factor, the error flag (SM492 (basic cycle)/SM493 (medium speed cycle)/SM494 (low speed cycle)) for the corresponding cycle will turn on, and the number of errors (SD492 (basic cycle)/SD493 (medium speed cycle)/SD494 (low speed cycle)) in the corresponding cycle will be counted up.

(3) Since interrupts are enabled, the network communication cycle synchronous interrupt program is executed.

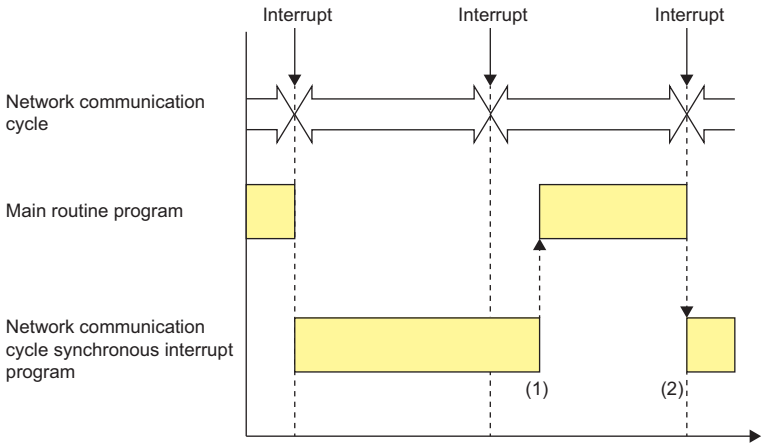
■If an interrupt factor with the same or a lower priority occurs while the interrupt program is being executed

After an interrupt occurs in the network communication cycle, the operation differs depending on whether or not the interrupt program being executed ends before the next cycle.

Program	Interrupt priority
I49 interrupt program	3
I48 interrupt program	5
Network communication cycle synchronous interrupt program	6

(1) The network communication cycle synchronous interrupt program is executed because the I49 interrupt program with the higher priority has finished before the next cycle.

(2) The network communication cycle synchronous interrupt program is executed because the I48 interrupt program whose priority is the same but whose priority order is higher has finished before the next cycle.



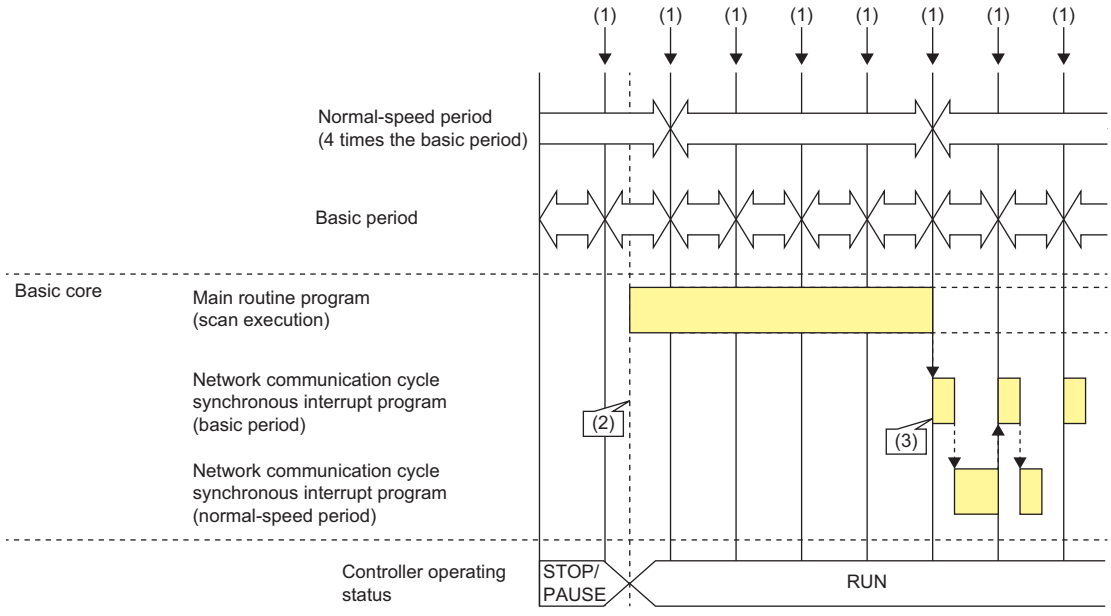
(3) The network communication cycle synchronous interrupt program is not executed because the end of the I49 interrupt program exceeded the second network communication cycle. If the network communication cycle synchronous interrupt program cannot be executed due to this factor, the error flag (SM492 (basic cycle)/SM493 (medium speed cycle)/SM494 (low speed cycle)) for the corresponding cycle will turn on, and the number of errors (SD492 (basic cycle)/SD493 (medium speed cycle)/SD494 (low speed cycle)) in the corresponding cycle will be counted up.

(4) Since the I49 interrupt program has finished, the network communication cycle synchronous interrupt program is executed.

■If the same interrupt factor occurs while the interrupt program is being executed

If an interrupt factor which is the same as that for the running interrupt program occurs, the factor is not memorized. Therefore, the network communication cycle synchronous interrupt program will not be executed after the running interrupt program finishes.

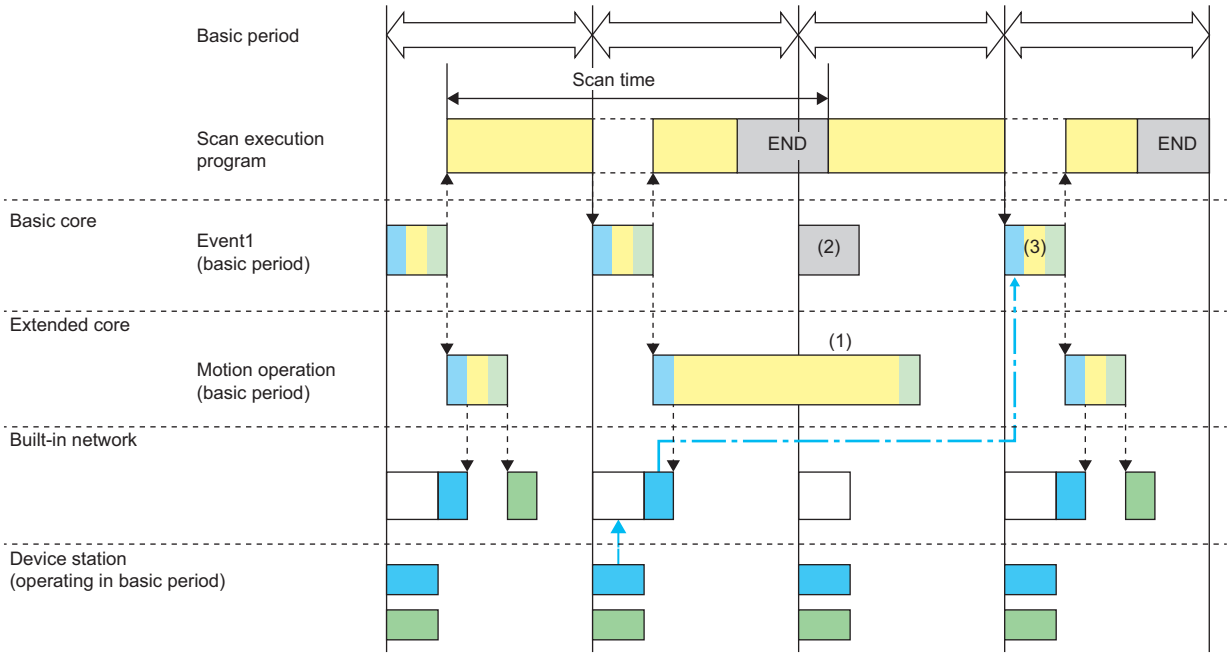
If the network communication cycle synchronous interrupt program cannot be executed due to this factor, the error flag (SM492 (basic cycle)/SM493 (medium speed cycle)/SM494 (low speed cycle)) for the corresponding cycle will turn on, and the number of errors (SD492 (basic cycle)/SD493 (medium speed cycle)/SD494 (low speed cycle)) in the corresponding cycle will be counted up.



(1) Since the network communication cycle synchronous interrupt program is running, it will not be executed even if the same interrupt factor occurs.
(2) The network communication cycle synchronous interrupt program is executed by the following interrupt factors.

■If an interrupt factor occurs in the STOP/PAUSE state

The interrupt factor that has occurred in the STOP/PAUSE state is not memorized, and therefore the network communication cycle synchronous interrupt program will not be executed even when the controller enters the RUN state and interrupts are enabled.

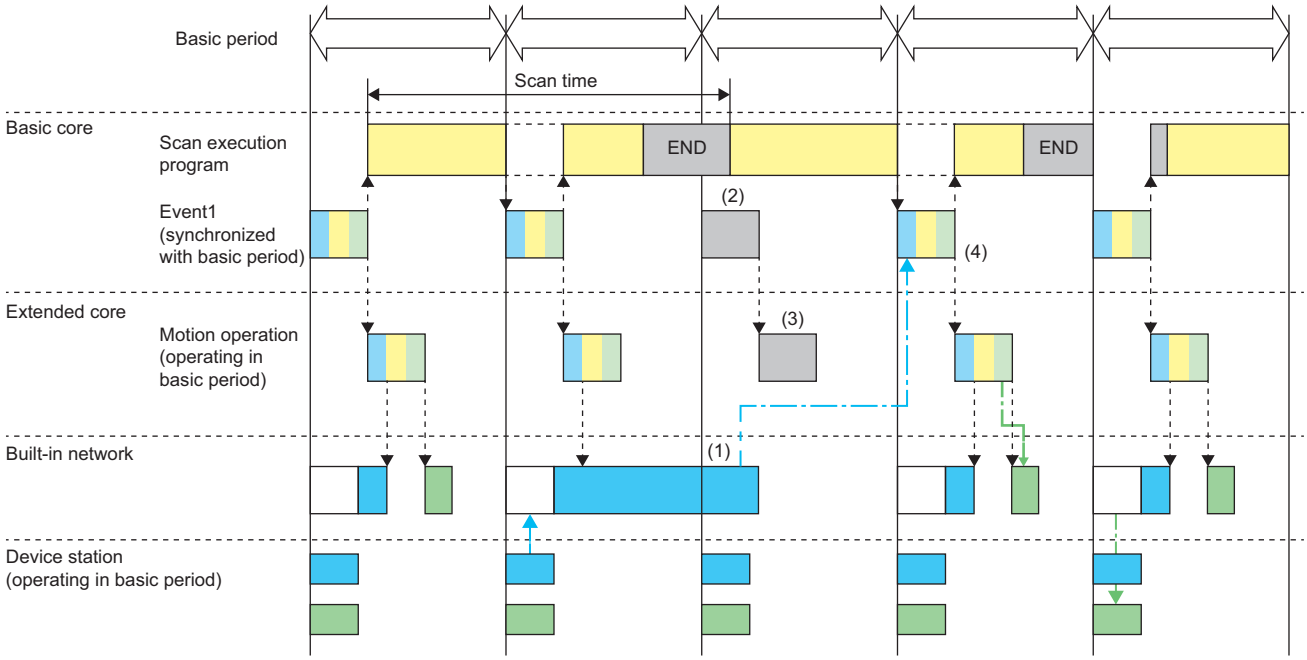


When the controller enters the RUN state and an interrupt occurs, the network communication cycle synchronous interrupt program is executed. Also, if there are network communication cycle synchronous interrupt programs with different operation cycles, the network communication cycle synchronous interrupt program is executed in the first cycle (1/N cycle) of the slowest cycle after the status changes to RUN.

(1) Interrupt
(2) The network communication cycle synchronous interrupt program is not executed because an interrupt factor has occurred in the STOP/PAUSE state.
(3) The network communication cycle synchronous interrupt program is executed from the beginning cycle (1/N cycle) of the slowest cycle.

■If the motion operation processing is not completed

When the motion operation processing is set to synchronize with the same communication cycle as the network communication cycle synchronous interrupt program, the network communication cycle synchronous interrupt program will not be executed if the motion operation processing for the previous cycle has not been completed.

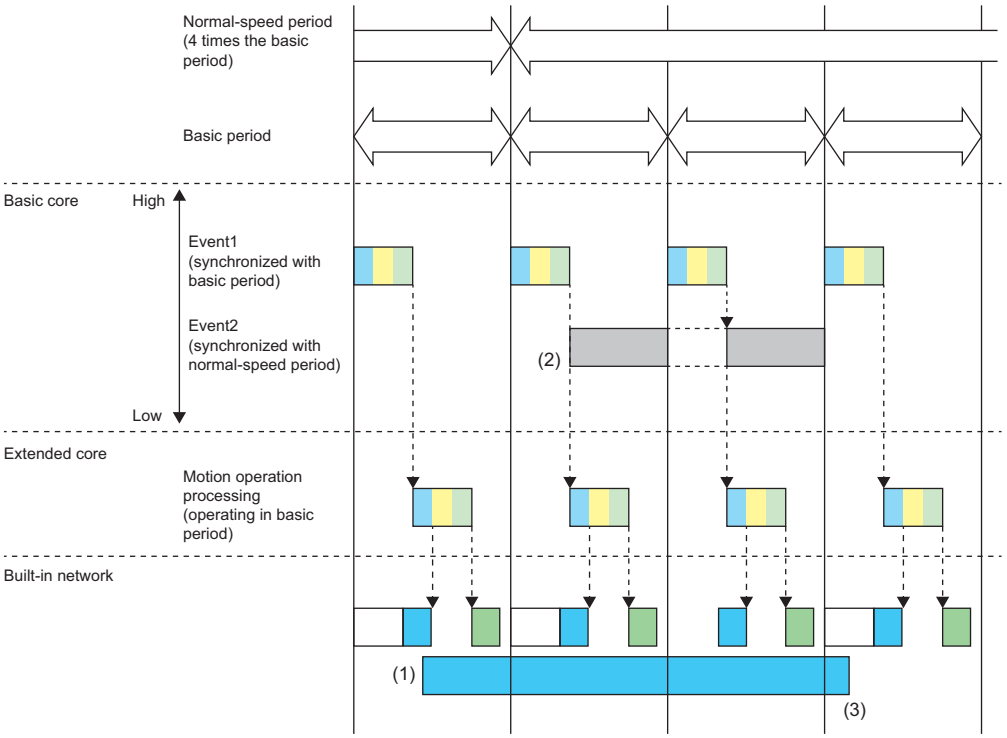


(1) The motion operation of the previous cycle has not been completed.
(2) The program for Event1 (synchronized with the basic cycle) is not executed because motion operation is in progress.
(3) The program for Event1 (synchronized with the basic cycle) is executed.

If the network communication cycle synchronous interrupt program cannot be executed, the error flag (SM492 (basic cycle)/SM493 (medium speed cycle)/SM494 (low speed cycle)) for the corresponding cycle will turn on, and the number of errors (SD492 (basic cycle)/SD493 (medium speed cycle)/SD494 (low speed cycle)) in the corresponding cycle will be counted up.

■When the network communication processing is not completed

If the network processing of the previous cycle has not been completed, the current network communication cycle synchronous interrupt program will not be executed.

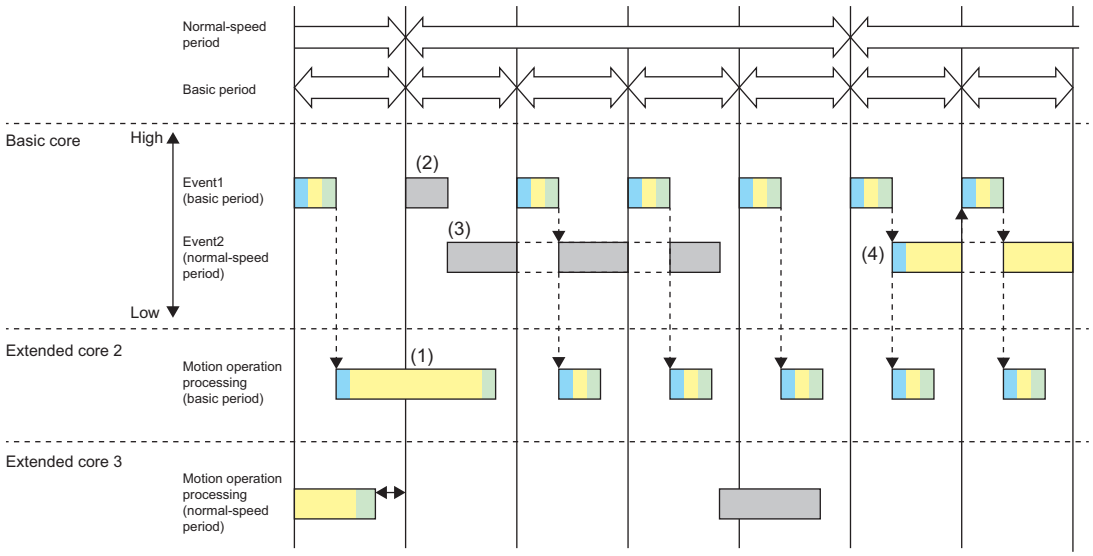


The network communication cycle synchronous interrupt program that synchronizes with the basic cycle will not be executed unless the network communication processing is completed when the conditions are met.

(1) Network communication processing (cyclic send/receive) in the previous cycle has not been completed.
(2) The program for Event1 (synchronized with the basic cycle) is not executed because the network communication is in progress.
(3) Since the program for Event1 (synchronized with the basic cycle) was not executed, the program for motion operation (operating at the basic cycle) will not be executed.
(4) The program for Event1 (synchronized with the basic cycle) is executed.

If the network communication cycle synchronous interrupt program cannot be executed, the error flag (SM492 (basic cycle)/SM493 (medium speed cycle)/SM494 (low speed cycle)) for the corresponding cycle will turn on, and the number of errors (SD492 (basic cycle)/SD493 (medium speed cycle)/SD494 (low speed cycle)) in the corresponding cycle will be counted up.

If the network communication processing is not completed when the conditions are met, the network communication cycle synchronous interrupt program that synchronizes with a cycle other than the basic cycle waits for the completion of network communication processing until 1/2 of each communication cycle.
If the network communication processing is not completed even after 1/2 of the communication cycle is exceeded, the network communication cycle synchronous interrupt program will not be executed.



(1) Cyclic receive processing (medium speed cycle)
(2) Since cyclic receive processing (medium speed cycle) is in progress, the program waits for completion of the processing.
(3) The program for Event2 (synchronized with the basic cycle) is not executed because the network communication processing was not completed before 1/2 of the medium speed cycle passed.

■When the network communication cycle synchronous interrupt program that synchronizes with a communication cycle with a small division ratio is not running

The network communication cycle synchronous interrupt program that synchronizes with a communication cycle other than the basic cycle will not be executed in conjunction with other network communication cycle synchronous interrupt programs not being executed.

The network communication cycle synchronous interrupt program that meets all of the following conditions will not be executed.

- The execution condition is met at the same time as another network communication cycle synchronous interrupt program.
- Another network communication cycle synchronous interrupt program whose execution condition is met at the same time is not executed.
- The network communication cycle synchronous interrupt program synchronizes with a communication cycle having a larger division ratio than the other network communication cycle synchronous interrupt programs that have not been executed.

(1) The motion operation (basic cycle) of the previous cycle has not been completed.
(2) This program will not be executed because motion operation (basic cycle) is in progress.
(3) At the same time, since the program that synchronizes with the basic cycle that meets the condition is not executed, the program that synchronizes with the medium speed cycle is not executed either.
(4) The program for Event2 (synchronized with the basic cycle) is executed.

If the network communication cycle synchronous interrupt program cannot be executed due to this factor, the error flag (SM492 (basic cycle)/SM493 (medium speed cycle)/SM494 (low speed cycle)) for the corresponding cycle will turn on, and the number of errors (SD492 (basic cycle)/SD493 (medium speed cycle)/SD494 (low speed cycle)) in the corresponding cycle will be counted up.

Precautions

- To avoid interfering with the execution of the network communication cycle synchronous interrupt program, do not perform the following operation. Otherwise, a network communication cycle synchronization processing error (error code 11F0H, 11F1H) may occur.

Interference operation	Workaround
Disable interrupts by executing the DI instruction.	Ensure that the network communication cycle synchronous interrupt program is not disabled by using the DI instruction with an argument.

- Note the following when setting the link device assigned to the synchronous station of CC-Link IE TSN as the event program trigger.
  - Specify the refresh target device of the same link device.
  - If the same link device is specified by U□\G□ (module access device) and Jn\□ (link direct device), no trigger will be established.
- If a network communication cycle synchronization error (11F0H) occurs, revise the processing contents of the network communication cycle synchronous interrupt program so that the processing can be completed within the interval set in the communication cycle interval setting. (☞ Page 308 Adjustment by reviewing immediately before processing)
- For the precautions on the network communication cycle synchronous interrupt priority, refer to the following.

☞ Page 277 Network communication cycle synchronous interrupt priority setting

16.3 Communication Cycle Adjustment

Adjust the communication cycle interval of CC-Link IE TSN if the motion system needs to be optimized or if cycle over occurred.
This section describes how to re-set "Communication Period Interval Setting" and "Cyclic Transmission Time" and how to review the processing performed immediately before.
☞ Page 306 Adjustment by "Communication Period Interval Setting" and "Cyclic Transmission Time"
☞ Page 308 Adjustment by reviewing immediately before processing

Adjustment by "Communication Period Interval Setting" and "Cyclic Transmission Time"

Adjust the values of "Communication Period Interval Setting" and "Cyclic Transmission Time" in "Communication Period Setting" under "Basic Settings".
When performing the network communication cycle synchronization, set the device station and use the network communication cycle synchronous interrupt program that matches the setting of the device station. (☞ Page 286 Network Synchronous Communication)

Adjustment procedure

1. Set the default values for "Communication Period Interval Setting" and "Cyclic Transmission Time" in "Communication Period Setting" under "Basic Settings". (☞ Page 287 Basic period setting)
2. Write the program to the controller.
3. Set SD972 (Communication cycle intervals measure setting) to A501H (Communication cycle interval measure enabled). (☞ Page 1996 Latch area)
4. Turn on SM972 (communication cycle intervals measure setting request) to enable actual value measurement. (☞ Page 1959 Latch area)
5. Reset the controller.
6. Check if any errors other than the cycle over error have occurred, and take action if any are found. (☞ Page 1776 ERROR CODES)
7. Check if the cycle over has occurred. (☞ Page 307 Cycle over check)
8. If the cycle over has occurred or "Communication Period Interval Setting" is to be smaller than the current setting value, reset the setting as follows.

- Set a value larger than Communication cycle intervals (actual measurement value) (U3E0\G10200 to U3E0\G10201) for "Communication Period Interval Setting".
- Set "Cyclic Transmission Time" according to Cyclic transmission time (calculation value) (U3E0\G10272 to U3E0\G10273).

However, review the communication cycle interval and cyclic transmission time settings so that the transient transmission time does not fall below the lower limit values[*1].

*1 The lower limit values of the transient transmission time are as follows:
· A master station communication speed of 1Gbps: 14μs
· A master station communication speed of 100Mbps: 140μs

Point

If the cycle over occurs even after re-setting, set a sufficiently large value in "Communication Period Interval Setting" to check that the cycle over does not occur. Then, set the value again referring to Communication cycle intervals (actual measurement value) (U3E0\G10200 to U3E0\G10201).

9. After the adjustment is completed, set a value other than A501H (Communication cycle intervals measure disabled) in SD972 (Communication cycle intervals measure setting) and turn off SM972.
10. Reset the controller.

■Cycle over check

Cycle over indicates a status in which the processing performed for each communication cycle was not completed within the communication cycle.

In this case, the following error occurs.

Error code/event code	Error name/detected event
Error code 11F0H	Network communication cycle synchronization error
Error code 11F1H	Network communication cycle synchronization error
Error code 1A00H	Cycle over
Error code 1860H	Network synchronous communication function transmission skip detection
Error code 1863H	Network communication cycle over
Error code 2600H	Network synchronous communication function processing error
Error code 3402H	Cycle over
Error code 3A6FH	Network communication cycle over
Event code 00F08H	Cycle over warning

Point

When the network communication cycle synchronization is performed, interrupts may be disabled as a cause of cycle over. If interrupts are disabled with the DI instruction, restore the interrupt enabled state with the EI instruction within the communication cycle.

Adjustment by reviewing immediately before processing

The processing executed immediately before cyclic send processing is stored in 'Processing immediately before cyclic send processing' (U3E0\G10202). (☞ Page 2041 Details of buffer memory addresses (CPU function part))
From the contents of the stored processing, one can determine which processing or settings can be reviewed to shorten the communication cycle and adjust it.

Point

If the network communication cycle synchronization is not performed, correct the parameter settings by referring to the following to shorten the cyclic receive processing (basic cycle).
☞ Page 2116 Shortening method of the communication cycle interval and cyclic transmission time
After that, reset the controller and set the cyclic transmission time again by referring to the value stored in 'Cyclic transmission time (calculation value)' (U3E0\G10272 to U3E0\G10273).

Adjustment procedure

1. Check the value stored in 'Processing immediately before cyclic send processing' (U3E0\G10202). If the stored value is zero, wait until another value is stored.
2. Based on the value of 'Processing immediately before cyclic send processing' (U3E0\G10202), review the following items.

Value of U3E0\G10202	Content of processing immediately before cyclic send processing	Action to be taken
0	Undetermined	Wait until another value is stored.
1	Synchronous station (basic cycle) output refresh or motion operation (basic cycle) output processing	Correct the processing to shorten the following processing times. • Input refresh and output refresh of synchronous station (basic cycle) • Execution of program (synchronized with the basic cycle) • Input processing and output processing of motion operation (basic cycle) • Operation processing of motion operation (basic cycle)
2	Synchronous station (medium speed cycle) output refresh or motion operation (medium speed cycle) output processing	Correct the processing to shorten the following processing times. • Input refresh and output refresh of synchronous station (medium speed cycle) • Execution of program (synchronized with the medium speed cycle) • Input processing and output processing of motion operation (medium speed cycle) • Operation processing of motion operation (medium speed cycle) • Input refresh and output refresh of synchronous station (basic cycle) • Execution of program (synchronized with the basic cycle)
3	Synchronous station (low speed cycle) output refresh or motion operation (low speed cycle) output processing	Correct the processing to shorten the following processing times. • Input refresh and output refresh of synchronous station (low speed cycle) • Execution of program (synchronized with the low speed cycle) • Input processing and output processing of motion operation (low speed cycle) • Operation processing of motion operation (low speed cycle) • Input processing and output processing of motion operation (medium speed cycle) • Operation processing of motion operation (medium speed cycle) • Input refresh and output refresh of synchronous station (basic cycle) • Execution of program (synchronized with the basic cycle) • Input refresh and output refresh of synchronous station (medium speed cycle) • Execution of program (synchronized with the medium speed cycle)
5	Cyclic receive processing (basic cycle)	Correct the processing to shorten the following processing times. • Cyclic transmission time • Cyclic receive processing (basic cycle)

For the review of each item, refer to the following.

Item	Reference
Input refresh and output refresh of synchronous station	In the network configuration settings, correct either or both of the following parameter settings for device stations whose review target cycle is set in the communication period setting and whose "Network Synchronous Communication" is set to "Synchronous". • Reduce the number of RX, RY, RWr, and RWw points of the target device station. • Reduce the number of connected modules for the target device station. For the parameter settings, refer to the following. ☞ Page 153 "CC-Link IE TSN Configuration" Window (Network Configuration Settings)
Program execution	In the CPU parameter program settings, modify the program of an event whose review target cycle is set in the execution type so that the execution time is shortened. ☞ Page 244 Program Setting
Input processing and output processing of motion operation	Refer to the following and correct the processing. ☞ Page 529 Operation cycle over check
Motion operation processing	
Cyclic transmission time Cyclic receive processing time (basic cycle) Cyclic send processing time	Correct the processing to shorten the processing times by referring to the following. ☞ Page 2116 Shortening method of the communication cycle interval and cyclic transmission time After that, reset the controller and set the cyclic transmission time again by referring to the value stored in 'Cyclic transmission time (calculation value)' (U3E0\G10272 to U3E0\G10273).

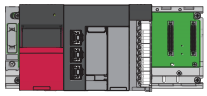
3. Write the corrective items , such as settings and program, to the controller.

4. Reset the controller or turn on b0 of 'Clear request of communication cycle intervals (actual measurement value)' (U3E0\G10270).

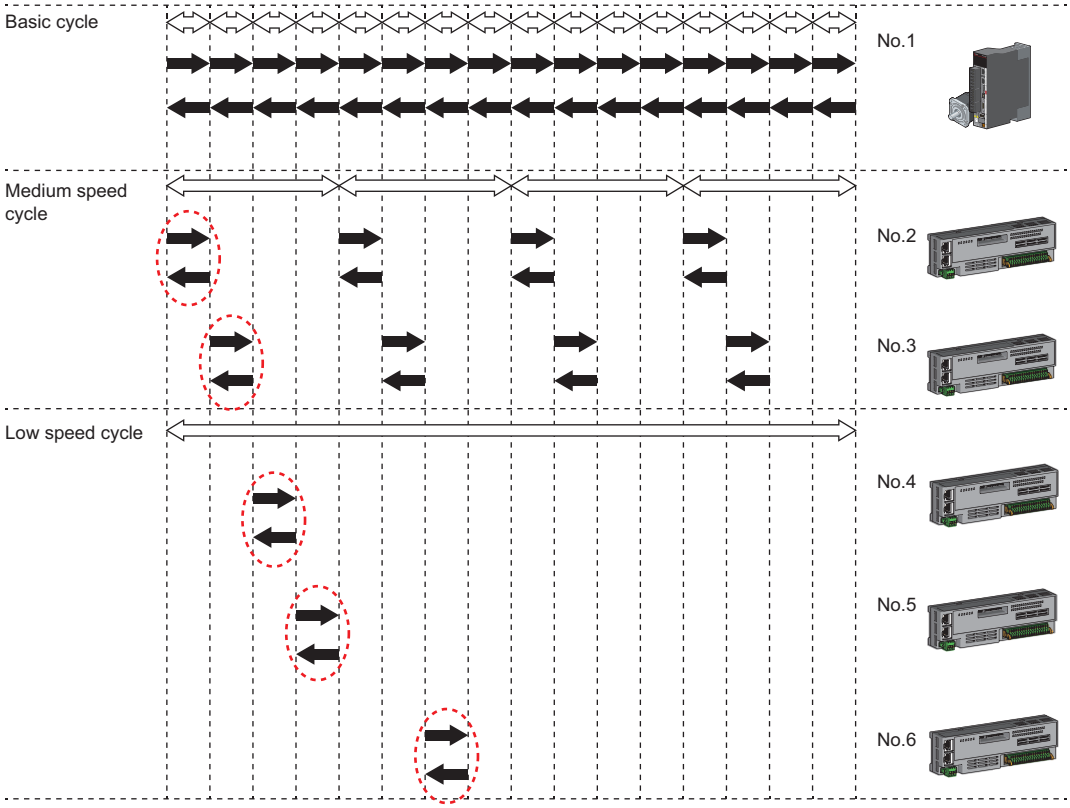
- If parameters has been changed or an error has occurred, reset the controller.
- If no parameter has been changed and no error has occurred, reset the controller or turn on b0 of U3E0\G10270.

5. Repeat the above procedure to shorten the communication cycle interval.

Actual measurement value of processing time



Refer to each processing time stored in the buffer memory areas in the following CPU function part to correct the processing to shorten these times.

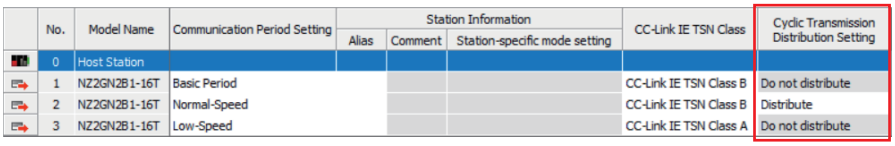


Address	Name	
U3E0\G10210, U3E0\G10211	Processing time of basic cycle	Input refresh time of synchronous station (basic cycle) [ns]
U3E0\G10212, U3E0\G10213		Program execution time (basic cycle) [ns]
U3E0\G10214, U3E0\G10215		Output refresh time of synchronous station (basic cycle) [ns]
U3E0\G10216, U3E0\G10217		Input processing time of motion operation (basic cycle) [ns]
U3E0\G10218, U3E0\G10219		Operation processing time of motion operation (basic cycle) [ns]
U3E0\G10220, U3E0\G10221		Output processing time of motion operation (basic cycle) [ns]
U3E0\G10222, U3E0\G10223	Processing time of medium speed cycle	Processing time of medium speed cycle [ns]
U3E0\G10224, U3E0\G10225		Input refresh time of synchronous station (medium speed cycle) [ns]
U3E0\G10226, U3E0\G10227		Program execution time (medium speed cycle) [ns]
U3E0\G10228, U3E0\G10229		Output refresh time of synchronous station (medium speed cycle) [ns]
U3E0\G10230, U3E0\G10231		Input processing time of motion operation (medium speed cycle) [ns]
U3E0\G10232, U3E0\G10233		Operation processing time of motion operation (medium speed cycle) [ns]
U3E0\G10234, U3E0\G10235		Output processing time of motion operation (medium speed cycle) [ns]
U3E0\G10236, U3E0\G10237	Processing time of low speed cycle	Processing time of low speed cycle [ns]
U3E0\G10238, U3E0\G10239		Input refresh time of synchronous station (low speed cycle) [ns]
U3E0\G10240, U3E0\G10241		Program execution time (low speed cycle) [ns]
U3E0\G10242, U3E0\G10243		Output refresh time of synchronous station (low speed cycle) [ns]
U3E0\G10244, U3E0\G10245		Input processing time of motion operation (low speed cycle) [ns]
U3E0\G10246, U3E0\G10247		Operation processing time of motion operation (low speed cycle) [ns]
U3E0\G10248, U3E0\G10249		Output processing time of motion operation (low speed cycle) [ns]
U3E0\G10264, U3E0\G10265	Cyclic processing time	Cyclic transmission time [ns]
U3E0\G10266, U3E0\G10267		Cyclic receive processing time (basic cycle) [ns]
U3E0\G10268, U3E0\G10269		Cyclic send processing time [ns]

Cyclic transmission distribution

If devices with different communication cycles coexist, the timing of cyclic transmission can be distributed for each station within the communication cycle of medium-speed and low-speed devices.

This distribution shortens the cyclic transmission time of the basic cycle and shortens the communication cycle interval.



Parameter setting

Set each device station in the "CC-Link IE TSN Configuration" window as shown below.

[Parameter] ⇨ Controller ⇨ [Module Parameter (Port 1/2: CC-Link IE TSN)] ⇨ [Module Parameter (CC-Link IE TSN)] ⇨ [Basic Settings] ⇨ [Network Configuration Settings]

	No.	Model Name	Communication Period Setting	Station Information			CC-Link IE TSN Class	Cyclic Transmission Distribution Setting
				Alias	Comment	Station-specific mode setting		
	0	Host Station						
	1	NZ2GN2B1-16T	Basic Period				CC-Link IE TSN Class B	Do not distribute
	2	NZ2GN2B1-16T	Normal-Speed				CC-Link IE TSN Class B	Distribute
	3	NZ2GN2B1-16T	Low-Speed				CC-Link IE TSN Class A	Do not distribute

Item	Description	Setting range
Cyclic Transmission Distribution Setting	Set whether or not to perform cyclic transmission distribution.	• Do not distribute (default) • Distribute

Point

Leave the default settings for "Communication Period Interval Setting" and "Cyclic Transmission Time" in "Communication Period Setting" under "Basic Settings".

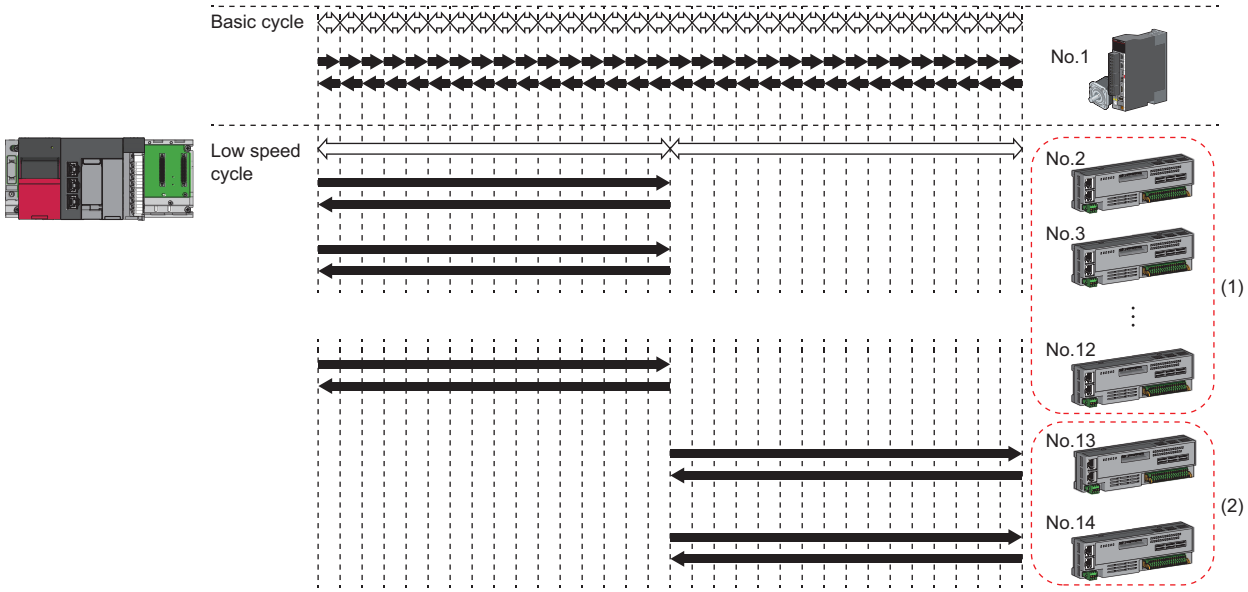
After setting the parameters, run the system, refer to the values stored in the buffer memory below, and re-set "Communication Period Interval Setting" and "Cyclic Transmission Time".

- Communication cycle intervals (actual measurement value) (U3E0\G10200 to U3E0\G10201)
- Cyclic transmission time (calculation value) (U3E0\G10272 to U3E0\G10273)

Devices that can perform cyclic transmission distribution

Cyclic transmission distribution can be performed with CC-Link IE TSN Class B devices that are set to "Normal-Speed" or "Low-Speed" in "Communication Period Setting" of the network configuration (CC-Link IE TSN configuration).

However, when "Communication Speed" of the master station is set to "1Gbps", cyclic transmission distribution cannot be performed to device stations with a communication speed of 100Mbps. For a device station with a communication speed of 100Mbps, set "Cyclic Transmission Distribution Setting" to "Do not distribute".



CC-Link IE TSN Class A group send

For CC-Link IE TSN Class A devices, device stations whose "Communication Period Setting" is set to "Low-Speed" are divided into groups according to the cyclic data size, and cyclic transmission is performed in group units.
Grouping is performed so that both of the following are within the specified size for each group.

- Total size of cyclic data sent from the master station to the device stations*1
- Total size of cyclic data that the master station receives from the device stations*1

*1 Refer to the following for the calculation method of the total size of cyclic data sent from the master station to a device station, as well as cyclic data which the master station receives from a device station.
☞ Page 2111 Details of n by which communication cycle intervals are multiplied

To shorten the communication cycle interval, select "2K bytes" for "CC-Link IE TSN Class A Group Send Upper Limit Size Setting". However, for CC-Link IE TSN Class A devices, the cyclic transmission delay time of device stations whose "Communication Period Setting" is set to "Low-Speed" will be longer. In this case, communication with one group is performed in one communication cycle.
For CC-Link IE TSN Class A devices, to shorten the cyclic transmission delay time of a device station whose "Communication Period Setting" is set to "Low-Speed", select "8K bytes". However, the communication cycle interval will become longer. In this case, communication with four groups is performed in one communication cycle.

(1) Stations with a total cyclic data size of up to 2K bytes are grouped as transmission number 1 and cyclic transmission is executed.
(2) Cyclic transmission is executed as a group with transmission number 2. If there are two groups, the communication cycle of CC-Link IE TSN Class A devices with low speed setting is calculated as follows: Communication cycle interval × Multiple specified in "Low-Speed" of "Multiple Period Setting" × 2.

Parameter settings

[Parameter] ⇨ Controller ⇨ [Module Parameter (Port 1/2: CC-Link IE TSN)] ⇨ [Module Parameter (CC-Link IE TSN)] ⇨ [Basic Settings] ⇨ [Connection Device Information]

Item	Description	Setting range
CC-Link IE TSN Class A Group Send Upper Limit Size Setting*1	Set the upper limit of the size of the cyclic data to be sent for each group of device stations whose "CC-Link IE TSN Class" is set to "CC-Link IE TSN Class A" and "Communication Period Setting" is set to "Low-Speed" in the network configuration settings.	• 2K bytes (default) • 8K bytes

*1 The setting is available when "CC-Link IE TSN Class Setting" is set to "Mixture of CC-Link IE TSN Class B/A or CC-Link IE TSN Class A Only".

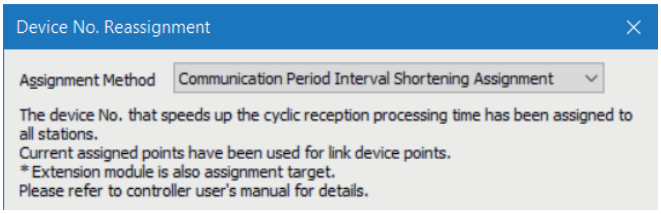
Point

Leave the default settings for "Communication Period Interval Setting" and "Cyclic Transmission Time" in "Communication Period Setting" under "Basic Settings".

After setting the parameters, run the system, refer to the values stored in the buffer memory below, and re-set "Communication Period Interval Setting" and "Cyclic Transmission Time".

- Communication cycle intervals (actual measurement value) (U3E0\G10200 to U3E0\G10201)
- Cyclic transmission time (calculation value) (U3E0\G10272 to U3E0\G10273)

Precautions



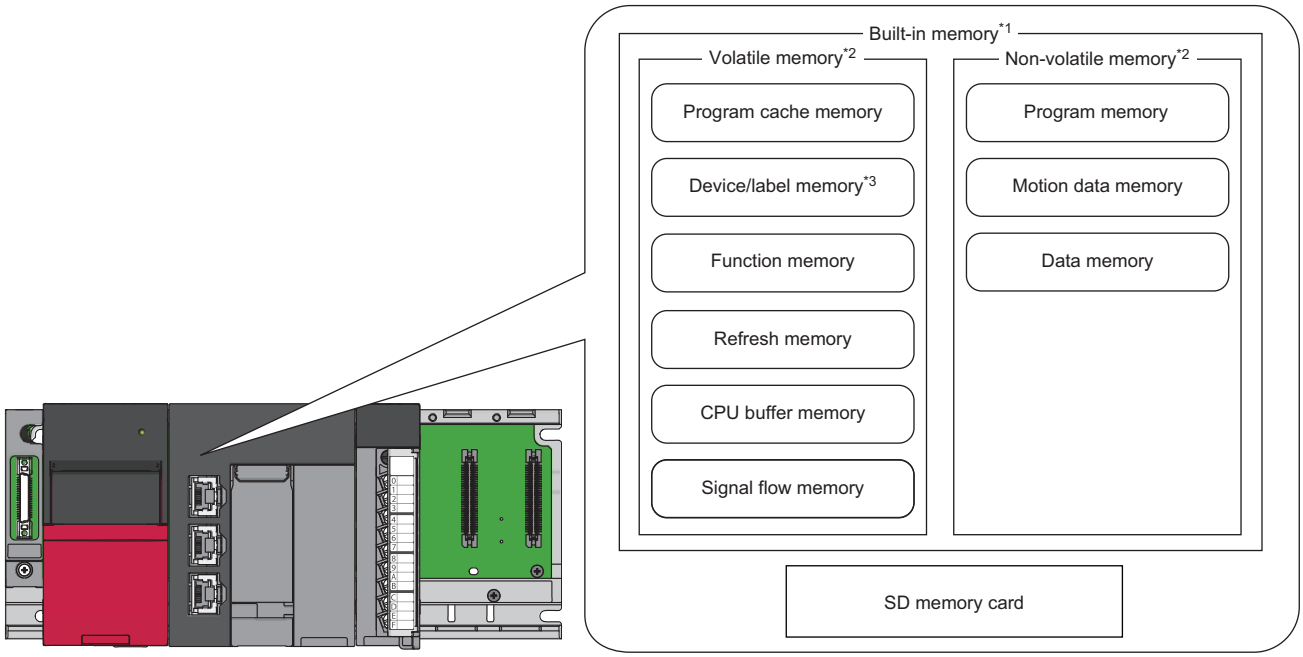
This setting may increase the cyclic transmission delay time of CC-Link IE TSN Class A devices with low speed setting.

Device number reassignment

Assign the device numbers successively to the link device of the specified target station.
For the number of link device points, the points assigned in the list of stations on the "CC-Link IE TSN Configuration" window are used.

Point

This setting shortens the communication cycle interval by assigning consecutive device numbers by selecting "Communication Period Interval Shortening Assignment" in the "Device No. Reassignment" window.



This setting also allows consecutive refresh devices to be more easily set in the refresh settings, creating a good potential of improvement in refresh performance.

For details on the setting, refer to the following.
☞ Page 169 Device number reassignment

17 CONTROLLER MEMORY CONFIGURATION

17.1 Memory Configuration

The following figure shows the memory configuration of the controller.

*1 The built-in memory is a generic term of the memory built in the controller.

*2 Non-volatile memory retains its contents even when the power is turned off. (Volatile memory does not retain its contents when the power is turned off.)

*3 Latch devices and latch labels are retained by transferring them to the built-in memory or SD memory card.

Point

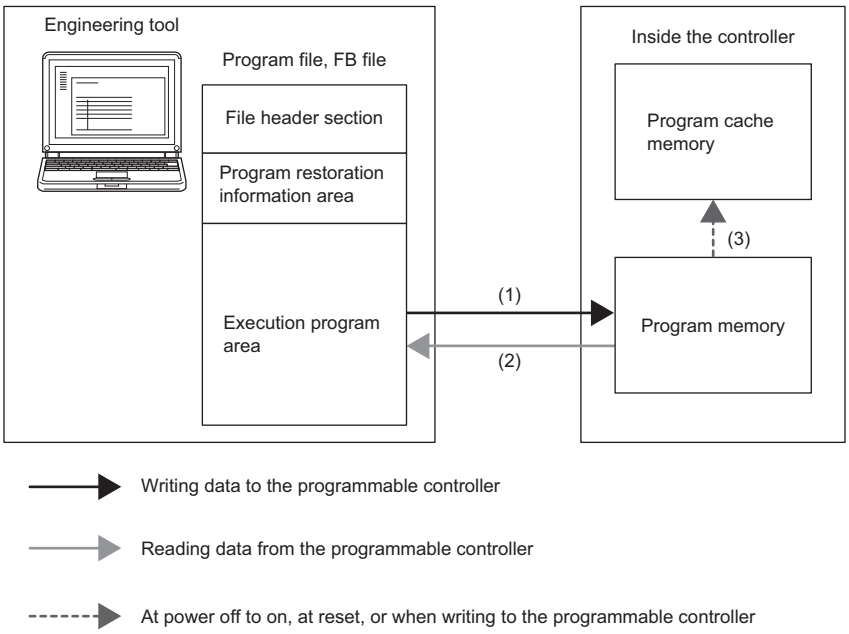
- The usage of the memory can be checked from the engineering tool. (GX Works3 Operating Manual)
- The number of writes for the program memory and data memory is limited to 50000 times. When using the function that the target file is written, pay attention to the number of writes. (☞ Page 336 File types and storage memory) The current number of writes for the program memory and data memory can be checked in the special register (SD630/SD631 and SD634/SD635). (☞ Page 1992 Drive information)

Program memory/program cache memory

The program memory and program cache memory store programs and parameters required for the controller to perform operations.

Data to be allocated

In the program memory, program files and FB files/parameter files are stored. In the program cache memory, program files and the execution program area in an FB file are allocated.



Program files and the execution program area in an FB file are transferred to the program cache memory and executed at the following timings.

- Powered-on
- Reset operation
- Writing data to the programmable controller

If the execution program size exceeds the program cache memory capacity, Program execution error (error code: 3209H, 41D9H) occurs at data transfer.

Data allocation and procedure of read/write operations

The following figure shows the data allocation of the program memory and the procedure of read/write operations from/to the programmable controller.

(1) When writing data to the programmable controller, program file/FB file data is written to the program memory.
(2) When reading data from the programmable controller, program file/FB file data is read from the program memory.
(3) After the controller is powered off and on or is reset, and when writing data to the programmable controller, the data in the execution program area is transferred to the program cache memory.

Point

For the read/write operations from/to the programmable controller, refer to the following.
GX Works3 Operating Manual

Capacity check

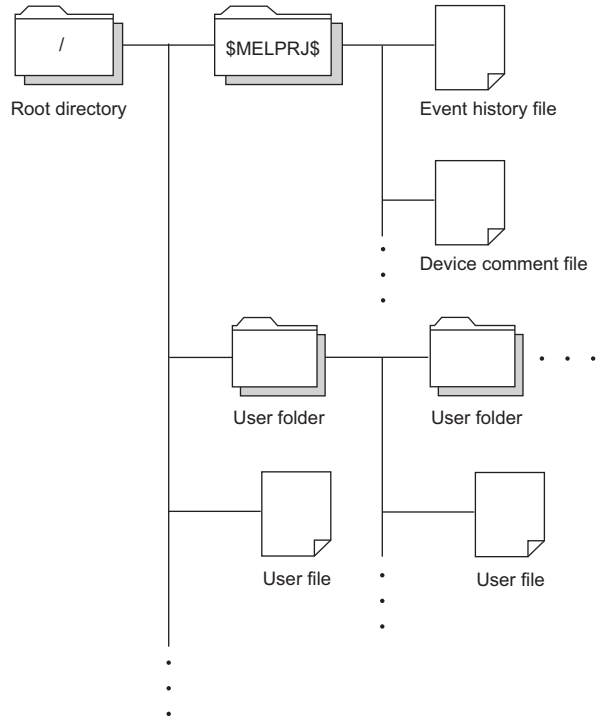
The capacity of program cache memory and free space can be checked by the following methods.

■Special register

- Program cache memory capacity: SD666 to SD667
- Program cache memory free space: SD668 to SD669

For details, refer to the following.

☞ Page 1992 Drive information



■Engineering tool memory capacity calculation (offline), online data operation window

For details, refer to the following.

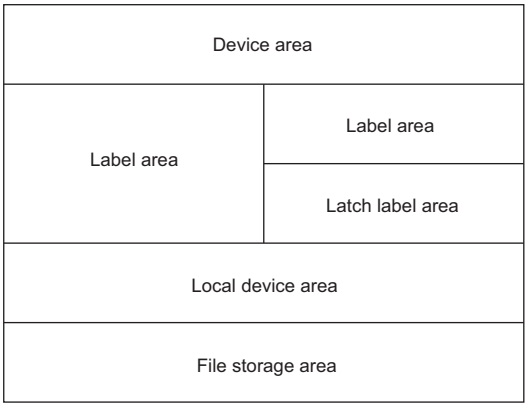
📖GX Works3 Operating Manual

Data memory

This memory is used to store the event history, device comment file, and/or the user's folder/file. Data such as the device comment files written by the engineering tool is stored in the "$MELPRJ$" folder. The "$MELPRJ$" folder is created after memory initialization. Note that the "$MELPRJ$" folder cannot be deleted. (Folders under the "$MELPRJ$" folder can be deleted.)

Point

For details on how to create and delete user folders, refer to the following.



GX Works3 Operating Manual

Precautions

Do not delete or rename the folders or files being accessed or those being executed by a function.

Device/label memory

The device/label memory has the following areas.

The capacity of each area can be changed with the setting of the CPU parameter. (☞ Page 320 Device/label memory area setting)

Data to be allocated

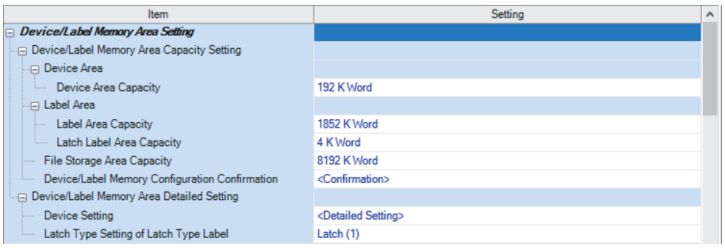
The following table lists the data allocated to each area.

Area		Application
Device area		User device
Label area	Label area	Global label and local label
	Latch label area	Global label and local label with latch specified
Local device area		Local device
File storage area		File register file and other data*1

*1 File register files which are stored in the area for storing file register files can be written or read in file unit.

Point

Free space of areas can be checked in "Device/Label Memory Area Capacity Setting". (☞ Page 320 Device/label memory area setting)



Device/label memory area setting

The capacity of each data area allocated within the device/label memory can be changed. (☞ Page 319 Device/label memory)

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Memory/Device Setting] ⇨ [Device/Label Memory Area Setting]

Operating procedure

"Device/Label Memory Area Setting" window

1. Set the capacity of each area in "Device/Label Memory Area Capacity Setting".

Displayed items

Item			Description	Setting range	Default
Device/Label Memory Area Capacity Setting	Device Area	Device Area Capacity	Sets the capacity of the device area to be used for global devices.	☞ Page 321 Setting range of capacity of each area	☞ Page 321 Default capacity of each area
	Label Area	Label Area Capacity	Sets the capacity of the label area to be used for global labels (including system-defined global labels) and local labels.		
		Latch Label Area Capacity	Sets the capacity of the latch label area to be used for latch type labels.		
	File Storage Area Capacity		Sets the capacity of the file storage area to be used for storing register files and others.		
	Device/Label Memory Configuration Confirmation		Shows the device/label memory configuration.		
Device/Label Memory Area Detailed Setting	Device Setting		☞ Page 347 Device Setting		
	Latch Type Setting of Latch Type Label		☞ Page 422 Setting latch on labels		

Point

- Please note that the total of the capacity of each area (including the capacity of the local device area) should not exceed the capacity of the device/label memory (☞ Page 210 Hardware specifications). The total of the capacity of each area can be checked in "Device/Label Memory Area Capacity Setting".
- When the capacity of the file storage area is changed, files (file register files) stored in the area are deleted, and therefore it is required to write file register files. Also, when files are stored in the controller, they must be read to other place before the capacity of the file storage area is changed and written back to the controller after the change.

Default capacity of each area

The default capacity of each area is as follows.

Item	MXR300-16, MXR300-32, MXR300-64	MXR500-128, MXR500-256
Device area	192K words	192K words
Label area	1852K words	1852K words
Latch label area	4K words	4K words
Local device area	57344K words	120832K words
File storage area	6144K words	8192K words

Point

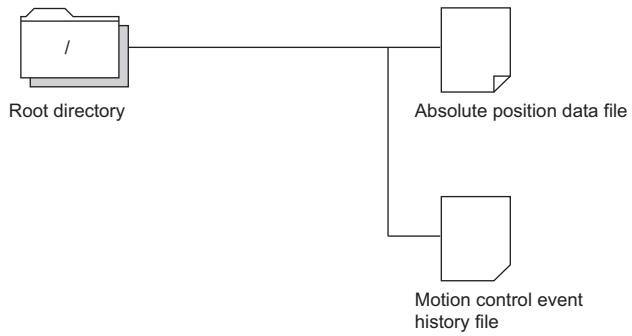
The capacity of the local device area to be set is obtained by deducting the total capacity of the device area, label area, latch label area, and file storage area from the total capacity of the device/label memory of each model.

Setting range of capacity of each area

The following tables lists the setting range of the capacity of each area on the device/label memory. *1

*1 The rest of other areas are automatically set as the capacity of the local device area.

Item	MXR300-16, MXR300-32, MXR300-64	MXR500-128, MXR500-256
Device area	2 to 8192K words	2 to 10240K words
Label area*2	0 to 65534K words	0 to 131070K words
Latch label area*3	• When built-in memory is specified: 0 to 896K words • When SD memory card is specified: 0 to 8190K words	• When built-in memory is specified: 0 to 1214K words • SD memory card: 0 to 10238K words
File storage area	0 to 8160K words	0 to 10208K words



*2 Secure the minimum capacity for system-defined global labels. The number of system-defined global labels used can be checked in "Information" in the "Output" window when "Convert" is executed with the content of the data "Global" not being set.

*3 The setting range differs according to the save destination of the latch data.

Motion data memory

This memory is used to store data used by motion control.

The motion data memory consists of non-volatile memory to store the data that needs to be latched.

Function memory

This memory is temporarily used for the specific function.

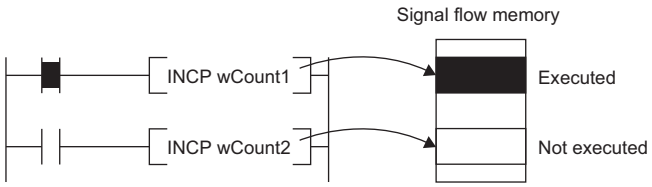
Folders are created for each of the following functions, and the capacity is managed by folder.

Folder name	Description	Size
backup	Used for the data backup/restoration function	64MB
LOGGING	Used for the data logging function	40MB
motion	Used for the motion function	32MB
other	Used for functions other than the above	32MB

Precautions

Do not delete or rename the folders or files being accessed or those being executed by a function.

Refresh memory



This memory is used to store data used to refresh communication with the network module, intelligent function module, and CC-Link IE TSN function part. (☞ Page 382 Refresh Data Register (RD))

Buffer memory

This memory is used by the network function or others for data communication. (☞ Page 2028 Buffer Memory)

Signal flow memory

This memory is used to memorize the execution status of the instruction in the last scan. The controller judges whether to execute a rising/falling edge execution instruction by referring to the signal flow memory.

The execution status of the last instruction is stored in the signal flow memory in two ways: executed or not executed. The instructions that refer to the signal flow memory judge whether to execute a rising/falling edge execution instruction depending on the input condition of the instruction and the execution status of the last instruction stored in the signal flow memory.
The same number of areas as the number of instructions that refer to the signal flow memory in the program are assigned. For function blocks, different areas are assigned to each instance.
For FB instances, refer to the following.
MELSEC MX Controller MX-R Model Programming Manual

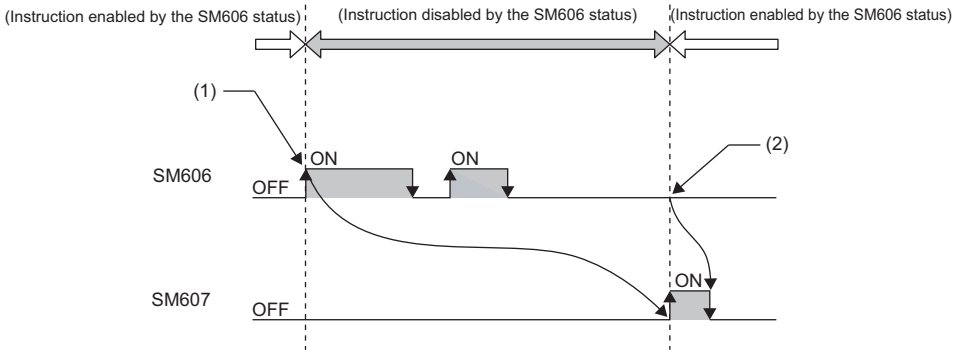
Point

The following shows the instructions that refer to the last execution status of the signal flow memory.

- Contact instruction: LDP, LDF, ANDP, ANDF, ORP, ORF, LDPI, LDFI, ANDPI, ANDFI, ORPI, and ORFI
- Association instruction: MEP, MEF
- Output instruction: SET F, RST F, PLS, PLF, FF
- Rising edge execution instruction: □P (such as INCP and MOVP), SP.□, ZP.□, GP.□, JP.□, DP.□, MP.□, UDCNT1, UDCNT2, TTMR, STMR, SORTD(_U), DSORTD(_U), LEDR, DUTY, TIMCHK, HOURM, DHOURM, PID, XCALL, SCJ

SD memory card

This memory is used to store the folder/file created by a function using the SD memory card as well as the user's folder/file. The folder configuration is the same as the data memory. (☞ Page 318 Data memory)
However, in the case of the SD memory card, the "$MELPRJ$" folder will be created when the SD memory card becomes available (when the SD memory card is mounted).



Point

For details on how to insert or remove the SD memory card, refer to the following.
☞ Page 57 Inserting and removing an SD memory card

How to forcibly disable the SD memory card with a special relay

If the SD memory card is removed while the controller is powered on, data in the SD memory card may be corrupted.
Use a special relay to forcibly disable access to the SD memory card without turning on and off the power.
The following shows how to forcibly disable the SD memory card with a special relay.

1. Turn on SM606 (SD memory card forced disable instruction). After an instruction by SM606, and until SM607 changes, an instruction by the ON/OFF state change of SM606 is disabled. Note that after SM607 changes, an instruction by the ON/OFF state change of SM606 is enabled, and operation is performed based on the ON/OFF state of SM606.

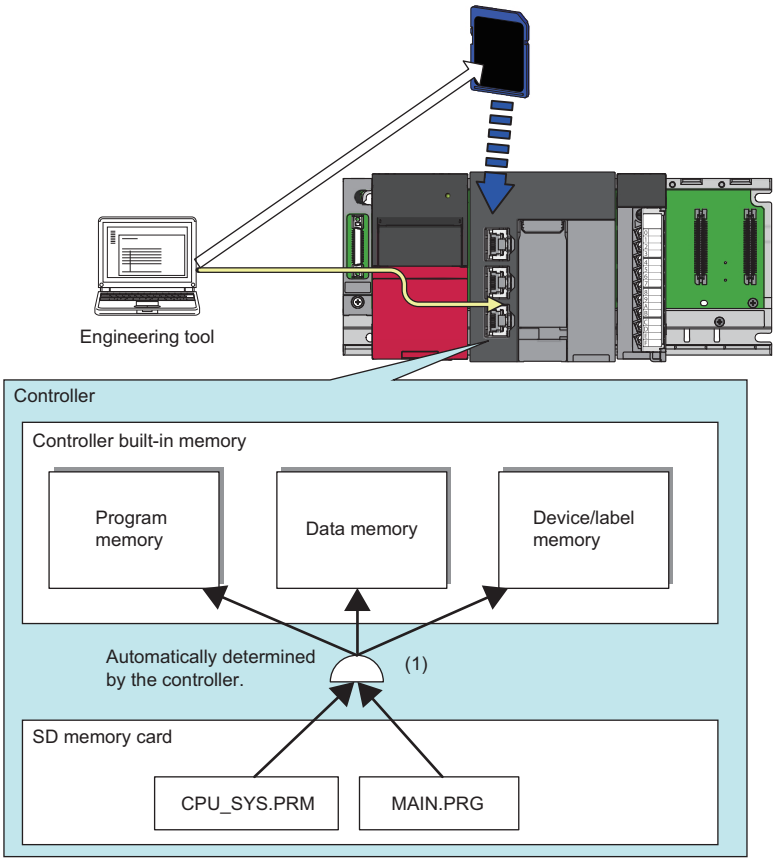
(1) Forced disable instruction by the ON state
(2) Instruction to cancel forced disable status by the OFF state enabled

2. Check that the CARD LED is off or SM607 (SD memory card forced disable status flag) is on.
3. Remove the SD memory card.

Point

If the SD memory card is disabled, take either of the following actions to cancel the disabled status:
- Insert the SD memory card again (the CARD LED changes from flashing to on).
- Power off and on or reset the controller.

■Operation of each function accessing the SD memory card



Disabling the SD memory card affects the operation of each function accessing the SD memory card.

- If the SD memory card forced disable function is executed while the SD memory card is being accessed, the SD memory card will be disabled after the current function being executed is executed to the end.
- If the SD memory card is accessed after the use of the SD memory card has been stopped, the same operation occurs as when the SD memory card is not installed, or an error (error code: such as 41D1H and 41FEH) occurs due to SM606 (SD memory card forced stop instruction).

Boot operation

The files stored on the SD memory card are transferred to the storage memory which is automatically determined by the controller when the controller is powered off and on or is reset.

(1) The boot operation is executed according to the boot file setting when the controller is powered on or is reset.

■Boot operation procedure

The boot operation procedure is as follows.

1. Configure the boot setting. (☞ Page 326 Boot setting)
2. Insert the SD memory card into the controller.
3. Write the boot setting and boot file to the SD memory card. (☞ Page 328 Writing boot settings and boot files)
4. Power off and on or reset the controller.

■Specifiable file types

The files which can be booted are as follows.

- System parameter
- CPU parameter
- Module parameter
- Module extension parameter
- Module extension parameter for protocol setting
- Global label*1
- Global label initial value
- Label initial value for each program
- Program file
- FB/FUN file
- Device comment
- Initial device value
- Operation profile data file*2

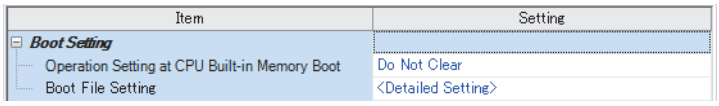
*1 Network label setting files are also booted. If a global label with the "Access from External Device" checkbox selected is set, the global label assignment information file is also booted.
For creating network labels, refer to the following.
☞ Page 108 Network labels

*2 The files stored in "$MELPRJ$/calc_profile_/" are booted.

■Allowed maximum number of boot files

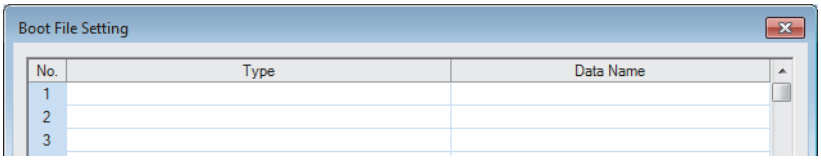
The number of boot file settings that can be specified is shown below.

Model	Allowed maximum number of boot files
MXR300-16, MXR300-32, MXR300-64	892
MXR500-128, MXR500-256	1084



■Boot setting

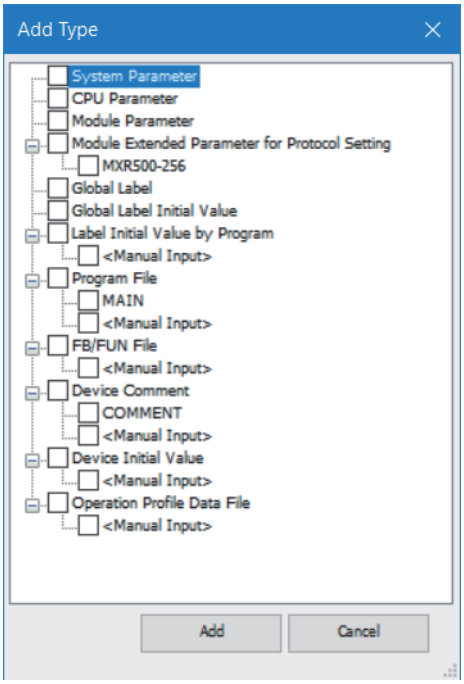
Configure the necessary settings for the boot operation.



Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [Memory Card Parameter] ⇨ [Boot Setting]

Operating procedure

"Boot Setting" window



"Boot File Setting" window

1. Click "Detailed Setting" on the "Boot File Setting" window.

2. Click the "Type" column. The maximum number of boot files that can be specified is the same as the number of files that can be stored in the storage memory.

"Add Type" window

3. Select type for the boot file. (Multiple selection is possible.)

"Boot File Setting" window

No.	Type	Data Name
1	System Parameter	SYSTEM
2	CPU Parameter	CPU
3	Module Parameter	UNIT
4	Module Extended Parameter for Protocol Setti	UEX3FF00
5	Global Label	GLBLINF
6	Global Label Initial Value	GLBLINF
7	Label Initial Value by Program	MAIN
8	Program File	MAIN
9	FB/FUN File	FbPou
10	Device Comment	COMMENT
11	Device Initial Value	MAIN
12	Operation Profile Data File	ProfileData001
13		

4. Set the data name (file name).

Displayed items

Item		Description	Setting range	Default
Operation Setting at CPU Built-in Memory Boot		Sets whether or not to clear the CPU built-in memory (program memory and data memory) upon file transfer from the SD memory card.	• Do Not Clear • Clear	Do Not Clear
Boot File Setting	Type	Select the file type of the boot file.	☞ Page 326 Specifiable file types	—
	Data Name	Set the file name of the boot file.	File name*1	—

*1 The boot file name is "SYSTEM" when the system parameter is specified, "CPU" when the CPU parameter is specified, and "UNIT" when the module parameter is specified.
When the module extension parameter is specified, the module extension parameter to be booted is selected. (It will be set as "UEX******".)

■Writing boot settings and boot files

Use the following functions of the engineering tool.

Function	Description
Write to PLC	Use this function to write the data to the SD memory card inserted into the controller. Click [Online] ⇨ [Write to PLC] on the menu bar.
Write to Memory Card	Use this function to write the data to the SD memory card inserted into the computer. Click [Tool] ⇨ [Memory Card] ⇨ [Write to Memory Card] on the menu bar.

Point

The boot settings and boot files cannot be written with a user-data-write operation of the engineering tool.

For details on write operations, refer to the following.

GX Works3 Operating Manual

■Precautions when using the boot operation

- If the transfer destination module is not installed, the boot file will not be transferred. Therefore, install all the modules that are set as the transfer destination in advance.
- When a parameter file is set as boot file, it overwrites the parameter file inside the transfer destination controller. In addition, if a parameter file is not set as boot file even when stored on the SD memory card, the controller operates in accordance with the settings in the parameter file inside it.
- When the transfer destination module is removed during boot execution, the boot file cannot be transferred normally. Therefore, after installing the transfer destination module, power off and on or reset the controller to execute boot.
- If a program in the program memory is changed online during boot operation, the change is also reflected in the transfer source program on the SD memory card.
- Note the model of the program written on the SD memory card (program specified in the boot file settings) and the model of the controller must be the same.
- For the boot file setting, check that the setting is consistent with the program/label setting. When the file is read from the programmable controller after the boot operation without consistency, functions such as conversion may not executed properly due to lack of consistency in project data.

Precautions

Do not delete or rename the folders or files being accessed or those being executed by a function.

■Powering off or resetting the controller during access to the SD memory card

Stop access to the SD memory card, power off or reset the controller, and remove the SD memory card.
If the above mentioned operation is performed during access to the SD memory card, data in the SD memory card (file system) may be corrupted.

- Data in the buffer memory is being saved to the SD memory card. (Data logging function is being executed.)
- During the folder delete by User Data Operation in the engineering tool

In this case, diagnostics of the SD memory card (such as a file system check or restoration processing) is performed when the controller is powered off and on and the SD memory card is inserted or the controller is changed from reset to reset release. If the SD memory card is in the following conditions, the diagnostic time will be longer, and it may take several minutes in some cases. (Note that the data may be not restored depending on the extent to which the file system is damaged.)

- The number of files is large.
- File fragmentation is progressing.

■Precautions when forcibly disabling the SD memory card

- When forced disable operation with the SD CARD OFF button and forced disable operation by SM606 are executed together, the operation executed earlier is enabled, and the operation executed later is disabled. For example, after the SD memory card is forcibly disabled with the SD CARD OFF button, when SM606 is turned on and off without removing the SD memory card, the disabled status of the SD memory card can be canceled. However, after forcibly disabling the SD memory card with the SD CARD OFF button, even by removing the SD memory card, turning on SM606, and inserting the SD memory card, the SD memory card is not enabled. To enable the SD memory card, after it is inserted again, SM606 must be turned off.
- If this function is executed while an external device is writing a file to the SD memory card, writing of the file may fail. Cancel the SD memory card disable status, then write the file again.

■Precautions when using the SD memory card in an environment where unauthorized access to the SD memory card may occur

Do not use the SD memory card in an environment where unauthorized access to the SD memory card may occur.
The following table lists the functions that uses the SD memory card and recommended alternative methods.

Function	Alternative method
Event history function	Specify data memory as the save destination of the event history file.
File operation instruction (SP.FREAD instruction, SP.FWRITE instruction)	• For the data input, use the device/label initial value instead of files. • For the data output, use the latch device/label.
Data logging function	• Set the logging setting file storage location to data memory. • Set the logging result file storage location to data memory or function memory.
Latch function	Specify the built-in memory in the save destination memory setting.
Boot operation	Do not use the boot operation. (Specify the built-in memory for writing data to the controller.)
Label access from external device function	Store label communication data in the program memory.
Device station parameter automatic setting	Store device station parameters in the data memory.
Predefined protocol support function	Store module extension parameters (including module extension parameters of the intelligent function module) in the data memory.
Writing user data	Store general-purpose files in the data memory.

17.2 Memory Capacity

For each memory capacity, refer to the following.

☞ Page 210 Hardware specifications

17.3 File Size Unit in Memory

The minimum unit of capacity for storing a file in the memory is referred to as the file size unit (cluster size).

File size unit based on memory area

Memory area	File size unit
Program memory	4K bytes
Data memory	4K bytes
Device/label memory	1K bytes
Function memory	4K bytes
Motion data memory	512 bytes

File size unit of each SD memory card

SD memory card	File size unit
NZ1MEM-2GBSD	32K bytes
NZ1MEM-4GBSD	
NZ1MEM-8GBSD	
NZ1MEM-16GBSD	

17.4 Number of Storable Files

For the number of storable files for each memory, refer to the following.

☞ Page 210 Hardware specifications

17.5 Number of Storage Folders

There is no restriction on the number of layers in the folder structure and it depends on the capacity of each memory where folders can be created.
If a folder cannot be created in memory where folders can be created, an error occurs.
The following table lists memory where folders can be created and the number of storable folders.

Name	Model	Number of storable folders*1
Data memory	MXR500-128, MXR500-256	7616*2
	MXR300-16, MXR300-32, MXR300-64	15244*2
Function memory	• MXR500-128, MXR500-256 • MXR300-16, MXR300-32, MXR300-64	*2
SD memory card	NZ1MEM-2GBSD	Root directory: 511*3 Under subdirectory: 65534*3
	NZ1MEM-4GBSD	Root directory: 65535*3 Under subdirectory: 65534*3
	NZ1MEM-8GBSD	Root directory: 65535*3 Under subdirectory: 65534*3
	NZ1MEM-16GBSD	Root directory: 65535*3 Under subdirectory: 65534*3

*1 The number of folders includes the system files and system folders.
*2 The maximum number of folders is the same as the upper limit for the number of files. (☞ Page 210 Hardware specifications)
*3 Total number of files and folders that can be stored in the root directory or subdirectory when the number of characters in a folder name (single-byte alphanumeric characters) is 8 or less. If the number of characters in the created folder name (single-byte alphanumeric characters) is 9 or more, the maximum number of folders that can actually be stored may be reduced because the number of consumed directory entries increases.

17.6 Drive Number Definition for Memory

The following table lists the drive number for each memory.

Name	Drive No.
Program memory	Drive 0
SD memory card	Drive 2
Device/label memory	Drive 3
Data memory	Drive 4
Function memory	Drive 5
Motion data memory	Drive 6

For file access using SLMP, FTP server functions, or FTP client functions, memory specification is required by the data storage location (drive number). The following table lists the combinations of drive numbers specified by the user and each memory.
○: Accessible, ×: Not accessible

Drive No.	File access destination	File access using SLMP	File access using FTP server functions	File access using FTP client functions
Drive 0	Program memory	×	×	×
Drive 2	SD memory card	○	○	○
Drive 3	Device/label memory	○	○	○
Drive 4	Data memory	○	○	○
Drive 5	Function memory	○	×	×
Drive 6	Motion data memory	○	○	○

17.7 Memory Operation

Initialization and value clear

Each memory can be initialized and cleared to zero by using the engineering tool. For details on the operation method, refer to the following.

GX Works3 Operating Manual

Items to be specified in the engineering tool				Target
Initialization	Program memory*1			Deletes all the folders and files in the program memory.
	Data memory*1			Deletes all the folders and files in the data memory.
	Device/label memory*1			Deletes all the files in the file storage areas in the device/label memory.
	Motion data memory*1			Deletes all the folders and files in the motion data memory.
	Function memory*1			Deletes all the folders and files in the function memory.
	SD memory card			Deletes all the folders and files in the SD memory card.
Value clear	All clear			Clears Latch (1), Latch (2), devices, labels, and file registers to zero.
	Device, label	Zero clear		Excluding devices and labels with latch specified, clears the following to zero: X, Y, M, B, F, SB, V, T, ST, LT, LST, C, LC, D, W, SW, FX, FY, FD, Z, LZ, RD, and all labels (including module labels).
		Zero clear (including Latches (1) and (2))		Including devices and labels with latch specified, clears the following to zero: X, Y, M, B, F, SB, V, T, ST, LT, LST, C, LC, D, W, SW, FX, FY, FD, Z, LZ, RD, and all labels (including module labels).
	File register	Zero clear	All files	Clears the contents of all the file registers to zero.
			File specification	Clears only the contents of the specified file register(s) to zero.
		Zero clear excluding Latch (2)		Clears the file registers other than Latch (2) to zero.
	Device / label / file register latch clear			Clears devices, labels, and file registers other than Latch (2) to zero.

*1 Initialization can be executed at the same time.

Point

- If the power goes off during initialization or zero clear, the memory is left in the state of that point, and it is necessary to re-execute the memory operation.
- If values including devices and labels are cleared, the device/label initial value is reflected the next time the operating status changes from STOP (PAUSE) to RUN. (☞ Page 426 DEVICE/LABEL INITIAL VALUE SETTINGS)

Memory initialization during execution of another function

Initialization cannot be executed while the function to access the file from the engineering tool is being executed. Check that the function to access the file is not being executed and then execute the initialization.

Clearing values during execution of another function

■Data backup/restoration function

During execution of the data backup/restoration function, devices, labels, file register areas, or latch areas cannot be cleared to zero. Check that the data backup/restoration function is not being executed and then clear devices, labels, file register areas, or latch areas to zero.

■Firmware update function

During execution of the firmware update function, devices, labels, file register areas, or latch areas cannot be cleared to zero. Check that the firmware update function is not being executed and then clear devices, labels, file register areas, or latch areas to zero.

■iQ Sensor Solution data backup/restoration function

During execution of the iQ Sensor Solution data backup/restoration function, file register areas cannot be cleared to zero. Check that the iQ Sensor Solution data backup/restoration function is not being executed and then clear file register areas to zero.

17.8 Memory Access Control

The controller uses the user authentication function to control access to some memory from external devices.

The following table lists the availability of access control to files in each drive.

Name	Drive No.	Access control availability
Program memory	Drive 0	Possible
SD memory card	Drive 2	Not possible*2
Device/label memory	Drive 3	Not possible*1
Data memory	Drive 4	Possible
Function memory	Drive 5	Not possible*2
Motion data memory	Drive 6	Not possible

*1 Access to files is not controlled, but access to devices/labels is controlled.

*2 Access to logging setting files (with extensions LAS and LIS) is controlled in accordance with the logging operation authority.

17.9 Target Memory for All Information Initialization

The following table lists the target memory that will be erased by the all information initialization of the controller.

Name	Drive No.	Delete target status
Program memory	Drive 0	Target
Program cache memory	—	Excluded
Data memory	Drive 4	Target
Device/label memory	Drive 3	Target
Signal flow memory	—	Excluded
Motion data memory	Drive 6	Target
Latch device/label memory	—	Target
Refresh memory	—	Excluded
CPU buffer memory	—	Excluded
Function memory	Drive 5	Target
SD memory card	Drive 2	Excluded

17.10 Files

This section lists the files used by the controller.

File/folder specifications

The following table shows the file/folder specifications.

Item		Specifications
File	File name	• Any character that can be expressed in Unicode can be used in the file name. (Any Unicode characters that are in the Basic Multilingual Plane (BMP) are supported.) Note that /*?<>|":[];,=+%'~@{}&^. and single-byte spaces cannot be used. • Uppercase and lowercase letters can be distinguished and displayed, but they are regarded as the same as file names.*1 • The file name can be up to 64 characters long, including the dot and extension. • The file name cannot be renamed to the same one. • The file path can be up to 255 characters long.
	Extension	The extension can be up to 4 single-byte alphanumeric characters. Uppercase and lowercase letters can be distinguished and displayed, but they are regarded as the same as file names.
	Creation/change date and time	Shows the date and time created or changed in the controller. The date and time are acquired from the controller clock The creation/change date and time of files/folders stored in the program memory, the data memory, and the function memory are affected by the time zone. Therefore, the display of the creation/change date and time of files/folders existing in the corresponding drive may change at the timing such as the time zone is changed by the parameter and daylight saving time is enabled.
	File size*2	Shows a value greater than or equal to 0 in bytes.
	Access right	The access rights to the file are shown below. • Administrators • Users • User-defined group
Folder	Folder name	• Any character that can be expressed in Unicode can be used in the folder name. Note that /*?<>|":[];,=+%'~@{}&^. and single-byte spaces cannot be used. • Uppercase and lowercase letters can be distinguished and displayed, but they are regarded as the same as file names. • The folder name can be up to 64 characters long. • The folder path can be up to 255 characters long.
	Creation/change date and time	Shows the date and time created or changed in the controller. The date and time are acquired from the controller clock

*1 Only full-width and half-width letters are considered to be the same as uppercase and lowercase alphabetic characters. Uppercase and lowercase letters in other languages are treated as different characters.

*2 There is no restriction on the file size per file. However, the operation is not guaranteed when handling files larger than 4GB to 1 byte (4294967295 bytes) with the controller.

File types and storage memory

This table lists the types of files, which are generated by parameter settings and functions in use, as well as their storage memory.

◎: Can be stored (Mandatory), ○: Can be stored, ×: Cannot be stored

File type		CPU built-in memory					SD memory card	File name and extension
		Program memory	Device/ label memory	Data memory	Function memory	Motion data memory		
		Drive 0	Drive 3	Drive 4	Drive 5	Drive 6	Drive 2	
Program		◎	×	×	×	×	○	ANY_STRING.PRG
FB file		○	×	×	×	×	○	ANY_STRING.PFB
CPU parameter		◎	×	×	×	×	○	CPU.PRM
System parameter		◎	×	×	×	×	○	SYSTEM.PRM
Module parameter		○	×	×	×	×	○	UNIT.PRM
Module extension parameter		×	×	○	×	×	○	• UEXmmmnn.PRM • UEXmmm00.PPR*1
Memory card parameter		×	×	×	×	×	○	MEMCARD.PRM
Device comment*2		×	×	○	×	×	○	ANY_STRING.DCM
Initial device value		○	×	×	×	×	○	ANY_STRING.DID
Global label setting file		○	×	×	×	×	○	GLBLINF.IFG
Network label setting file		○	×	×	×	×	○	NWLINF3FF00.IFG
Initial label value file	Initial global label value file	○	×	×	×	×	○	GLBLINF.LID
	Initial local label value file	○	×	×	×	×	○	PROGRAM_NAME.LID
Global label assignment information		○	×	×	×	×	○	• LDB****.GLA • GLBLINF.LLA
Local label assignment information		○	×	×	×	×	○	PROGRAM_NAME.LLA
Operation profile data file		×	×	○	×	×	○	ANY_STRING.csv
Operation profile data file additional information		×	×	○	×	×	○	OperateProfileAddInfo.json
Position data history file*2		×	×	○	×	×	×	PosHist.bin
Axis absolute position data file		×	×	×	×	○	×	abs_axis.bin
Axis absolute position data file (advanced synchronous control)		×	×	×	×	○	×	abs_advsync.bin
File register		×	○	×	×	×	○	ANY_STRING.QDR
Event history*2		×	×	○	×	×	○	EVENC.LOG
Motion control event history*2		×	×	×	×	○	×	EVENM.LOG
General-purpose data		×	×	○	×	×	○	ANY_STRING.CSV/BIN
Device data storage file		×	×	○	×	×	○	DEVSTORE.DST
Device station parameter file		×	×	○	×	×	○	SLAVEmmmnnnxxxx.NSP
Firmware update file*2		×	×	○	×	×	○	mmmm_vv.SYF
Firmware update prohibited file		×	×	○	×	×	○	FWUPDP.SYU
Firmware update information		×	×	○	×	×	○	ANY_STRING.zip

*1 When the operating status of the controller is STOP, write to the programmable controller. When the operating status is RUN, use the RUN change function. When the controller is in the RUN state, write operation is possible only if it has been registered in the parameter and the target file has been written to the controller.

*2 The module extension parameter for protocol setting is operated by writing, reading, or deleting user data.

*3 Operation is possible only when the operating status of the controller is STOP/PAUSE. A communication error occurs when operated in the RUN state.

*4 Operation is possible only when the operating status of the controller is STOP/PAUSE. When a program tries to perform memory operation while the controller is RUN, the operation is continued after the operation status is changed through remote STOP.

*5 When the operation target is the SD memory card, the operation can be performed even while the controller is RUN.

*6 Write operation can be performed using the engineering tool during RUN. For details on the engineering tool support, refer to the following.
GX Works3 Operating Manual

*7 File read/write operation is also performed from the CC-Link IE TSN master station (device station).

*8 Data can be sent to or received only from the SD memory card (Drive 2). It is not possible for the file storage location program memory (Drive 0).

*9 Data can be sent to or received only from the SD memory card (Drive 2). It is not possible for the file storage location data memory (Drive 4).

*10 If the transfer completion file deletion setting is enabled and file transmission (GP.FTPCPUT) is executed, the file cannot be transferred.

*11 Files whose name contains two or more dots cannot be transferred. Use one dot or no dot (file name only).

*12 Write, read, or delete it from the dedicated window of the engineering tool.

*13 Encrypted communication cannot be used when writing from other than the engineering tool. For encrypted communication, write the certificate from the dedicated window of the engineering tool.

*14 This item indicates operation on CPU Module Logging Configuration Tool.

*15 When the controller is in the RUN state, the file operation is available only when the target file is already written to the controller.

*16 SLMP and FTP commands cannot be used to access the program memory (drive 0).

*17 Use "MCv_ReadProfileData" to read the operation profile data, and use "MCv_WriteProfileData" to write the operation profile data. For details, refer to the following.
Page 824 OPERATION PROFILE DATA FUNCTION

*18 This is when the target memory is a memory card (Drive 2). Data memory (drive 4) can be operated only when the operating status is STOP/PAUSE. A communication error is returned when the operating status is RUN.

*19 When prohibiting operations is required for security, restrict access by using the user authentication function.

*20 When the target memory is the program memory (drive 0), the operation can only be executed while the OPC UA server is stopped.

*21 The operation is executed through the firmware update function window.

*22 In the user data operation, the confirmation window for whether to perform a remote STOP is not displayed. Therefore, a communication error will occur during RUN.

*23 The operation by user data operation can be operated regardless of the operating status of the controller.

17.11 Specifying Path for Motion Control

The program and parameters used in motion system control are stored in a file. The file storage destination can be freely specified using various control parameters and FB I/O variables.
The controller built-in memory and SD memory card can be used as data area for file storage.

Operation of this function for each system status

○: Available

System status	Operation availability
STOP	○
RUN	○
Moderate error	○
Major error	○

Drive configuration

The file storage memory and SD memory card slot of the motion system are collectively called a drive.
Drives that can be used in the motion system are as follows.

Item	Data memory	Function memory	Motion data memory	SD memory card
Application	For manufacturer	For manufacturer	• Absolute position data • Synchronized restore data	• Project data • General data
Drive identifier	/rom	/ram	/lch	/sdc

Specifying path

Specify the path (including the file name) of a file used in control by using various control parameters and FB I/O variables with STRING or FILE_LOCATION type label. The path specifications are as follows.

- The file path can contain alphanumeric characters (a-z, A-Z, 0-9), symbols (!#$%&'()+,-.;=@[]^_`{}~), space, and directory delimiters (/). Wide characters can be used.
- Depending on the function, wildcards (*?) can be used in the file name. Refer to each function for availability of wildcards.
- The maximum path length is 127 characters.
- The path setting is not case-sensitive.

How to specify a path

There are two ways to specify a path: absolute path and relative path.

■Absolute path

A path beginning with / is an absolute path. An absolute path must be expressed as a string that combines a drive identifier with a file name.
For the drive identifier and file name, refer to the following.
☞ Page 342 Drive configuration
☞ Page 336 File types and storage memory

Ex.
/sdc/$MELPRJ$/calc_profile_/cam0001.csv

■Relative path

A path that does not begin with / is a relative path. The actual file access is performed using root path + relative path. The root path varies depending on each function, so refer to the function to be used.

The following table lists the relative paths for add-on developers:

Specified root path %PROJECT_ROOT%*1	Specified root drive %PROJECT_ROOT_DRIVE%*1
/rom/$MELPRJ$/	/rom

*1 The root path is stored in the system-defined environment variable PROJECT_ROOT. Also, the drive name (root drive) containing the root path is stored in the environment variable PROJECT_ROOT_DRIVE.

Ex.

When relative path calc_profile_/cam0002.csv is specified

The actual file to be accessed becomes:

/rom/$MELPRJ$/calc_profile_/cam0002.csv

Special relative paths ./ (which indicates the current directory) and ../ (which indicates the directory above) can be used.

Ex.

When relative path: ../cam0002.csv is specified

The actual file to be accessed becomes:

/sdc/cam0002.csv

■Environmental variables

A path can contain environment variables. Environment variables are specified in the format "%environment variable name%".

The following table lists the system-defined environment variables.

Environmental variable	Description	Default value
PROJECT_ROOT	Root directory	/rom/$MELPRJ$
PROJECT_ROOT_DRIVE	Root drive	/rom
TEMP	Working directory	/ram/temp
CALC_PROFILE_ROOT	Operation profile data root directory	/rom/$MELPRJ$ (Varies depending on the operation profile data root drive (MotionSystem.PrConst.ProfileRootDrive))
CALC_PROFILE_ROOT_DRIVE*1	Operation profile data root drive	/rom (Varies depending on the operation profile data root drive (MotionSystem.PrConst.ProfileRootDrive))

*1 The drive part of CALC_PROFILE_ROOT.

■Drive No.

When accessing a file in a motion system via SLMP communications, the file is accessed using a path that combines the "file name" part in the drive identifier that corresponds to the "drive number" part of the SLMP message.

Working folder

When operating files with each function, a temporary work file may be created in the working folder (the folder indicated by the environment variable "%TEMP%"). Data in the working folder must not be changed or deleted. (An error may occur in the function being controlled.)

Precautions

File read/write

- File read/write is performed as background processes by the motion system. The read/write time varies depending on the file size and system load. This may result in longer time in system startup or switching from STOP to RUN.
- When the free space of the data memory becomes low, the write time may become longer.
- During file read/write, communication with the engineering tool may not be possible and may result in a timeout error. In this case, wait for a while and try the operation again.

Powering off (including reset) during file operation

- If a software reset is performed or the motion system is powered off or reset during a file operation other than data read, the file content is not guaranteed. To prevent data corruption, be sure to complete the file operation before turning the power off (including reset).
- When the motion system is initialized (or when an SD memory card is inserted), a consistency check is performed on the file system. If there are many files in the drive, the check may take some time.

Simultaneous access to the same file

If the following operations are executed using the engineering tool, SLMP, FTP server function, FTP client function, file operation instructions, or MCFB (such as MCv_ReadProfileData (profile read), MCv_WriteProfileData (profile write), and MC_CamTableSelect (cam table selection)), an error will occur in the request source. Execute the next access after the processing of one request source is completed.

- Perform operations (read/write/create/delete/move/copy/rename) on the same file from multiple request sources.

Simultaneous access to different files from multiple request sources

A maximum of 16 different files can be accessed simultaneously from different request sources.

PART 8 DEVICES, LABELS, AND CONSTANTS

This part consists of the following chapters.

18 DEVICES AND CONSTANTS

19 LABELS

20 LATCH FUNCTION

21 DEVICE/LABEL INITIAL VALUE SETTINGS

18 DEVICES AND CONSTANTS

This chapter describes devices and constants.

18.1 Device List

This section lists the devices.

Classification	Type	Device name	Symbol	Number of points of default	Changeability with parameter settings	Notation
User device	Bit	Input	X	12K points*1	Unchangeable	Hexadecimal
	Bit	Output	Y	12K points*1	Unchangeable	Hexadecimal
	Bit	Internal relay	M	64K points	Changeable (☞ Page 347 Device Setting)	Decimal
	Bit	Link relay	B	32K points		Hexadecimal
	Bit	Annunciator	F	2K points		Decimal
	Bit	Link special relay	SB	2K points		Hexadecimal
	Bit	Edge relay	V	2K points		Decimal
	Bit/word	Timer	T	1K points		Decimal
	Bit/word	Retentive timer	ST	0 points		Decimal
	Bit/double word	Long timer	LT	4K points		Decimal
	Bit/double word	Long retentive timer	LST	0 points		Decimal
	Bit/word	Counter	C	512 points		Decimal
	Bit/double word	Long counter	LC	512 points		Decimal
	Word	Data register	D	64K points		Decimal
	Word	Link register	W	32K points		Hexadecimal
	Word	Link special register	SW	2K points		Hexadecimal
	Bit	Latch relay	L	8K points		Decimal
System device	Bit	Function input	FX	—	Unchangeable	Hexadecimal

Link Special Register	SW	2K	0 to 7FF
Latch Relay	L	8K	0 to 8191
Total Device			38.4K Word
Total Word Device			34.5K Word
Total Bit Device			62.0K Bit

(1) The capacity of each area can be changed. (☞ Page 320 Device/label memory area setting)
(2) The number of points of user devices can be changed.

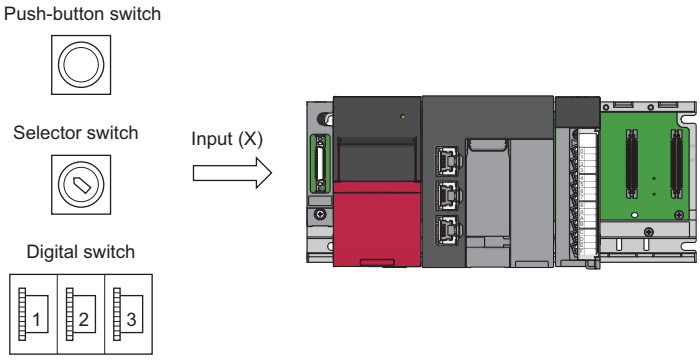
Point

Specify each item so that the total number of points for each user device does not exceed the capacity of the device area. (☞ Page 320 Device/label memory area setting)

Range of use of device points

The following table lists the range of use of device points to be set in the device setting.

Type	Device name	Symbol	Range of use	Increment of setting
Bit	Input	X	X0 to X2FFF	—
Bit	Output	Y	Y0 to Y2FFF	—
Bit	Internal relay	M	M0 to M167747583*1	64 points
Bit	Link relay	B	B0 to B9FF9FFF*1	64 points
Bit	Annunciator	F	F0 to F32767	64 points
Bit	Link special relay	SB	SB0 to SB9FF9FFF*1	64 points
Bit	Edge relay	V	V0 to V32767	64 points
Word	Timer	T	T0 to T9319295*1	32 points
Word	Retentive timer	ST	ST0 to ST9319295*1	32 points
Word	Long timer	LT	LT0 to LT2621055*1	1 point
Word	Long retentive timer	LST	LST0 to LST2621055*1	1 point
Word	Counter	C	C0 to C9319295*1	32 points
Word	Long counter	LC	LC0 to LC4933727*1	32 points
Word	Data register	D	D0 to D10484223*1	4 points
Word	Link register	W	W0 to W9FF9FF*1	4 points
Word	Link special register	SW	SW0 to SW9FF9FF*1	4 points
Bit	Latch relay	L	L0 to L32767	64 points



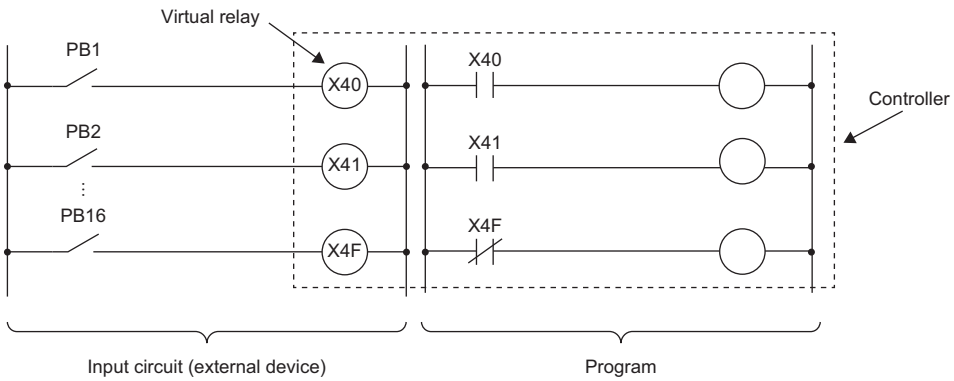
*1 The actual maximum usable device range depends on the usage of global labels.

18.3 User Device

This section describes the user device.

Input (X)

This device provides the controller with commands and/or data using an external device, such as pushbutton, transfer switch, limit switch, and digital switch.

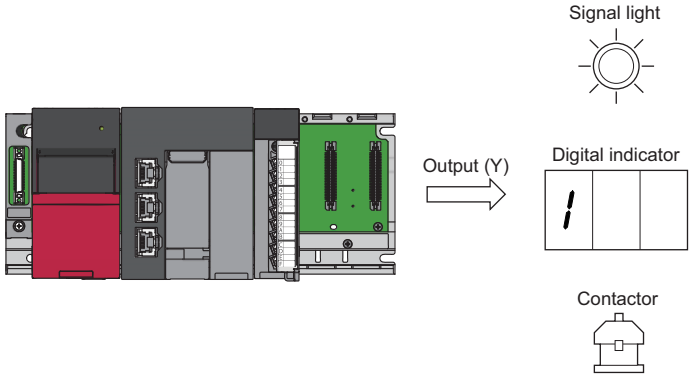


Point

For the input signal assignment of the controller itself, refer to the following.

☞ Page 1945 I/O Signals

Concept of input



Assume that one virtual relay Xn is incorporated into the controller for each input point. In the program, a normally open contact and normally closed contact for the Xn are used.

Also, the input can be used as a refresh target (controller side) device of the remote input (RX), such as the CC-Link IE TSN.

Output (Y)

This device outputs the control results of the program to various devices, such as external signal light/digital HMI/electromagnetic switch (contactor)/solenoid.

Point

For the output signal assignment of the controller itself, refer to the following.

☞ Page 1945 I/O Signals

Internal relay (M)

This device is used as an auxiliary relay within the controller. The following operations turn off all the internal relays.

- Controller powering off and on
- Reset
- Latch clear

Latch relay (L)

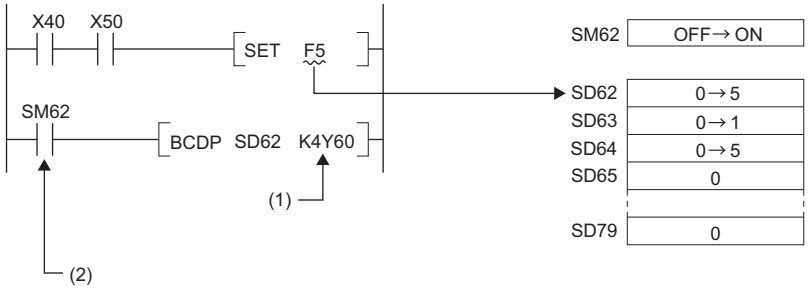
This device is an auxiliary relay which enables latching (data retention during power failure). This device is used within the controller. This device latches operation results (ON/OFF information) even after the following operations.

- Controller powering off and on
- Reset

Link relay (B)

This device is used as a controller side device when refreshing bit data between the network module and the controller.

Refreshing network modules using link relay



Data are transferred/received between the link relay (B) within the controller and the link relay (LB) of the network module, such as CC-Link IE TSN. The refresh range is specified using parameters on the network module. The part which is not used for refreshing can be used for other applications.

Annunciator (F)

This device is an internal relay used for a customer-created program which detects malfunction/failure of the equipment. When the annunciators are turned on, SM62 (Annunciator) is turned on, the number of activated annunciators and their device numbers are stored in SD62 (Annunciator number) to SD79 (Table of detected annunciator numbers).

Ex.

Failure detection program

(1) Outputs the annunciator number of the annunciator that turned on.
(2) ON detection of the annunciator

Also the number of the annunciator turned on first (the number stored in SD62) is registered in the event history.

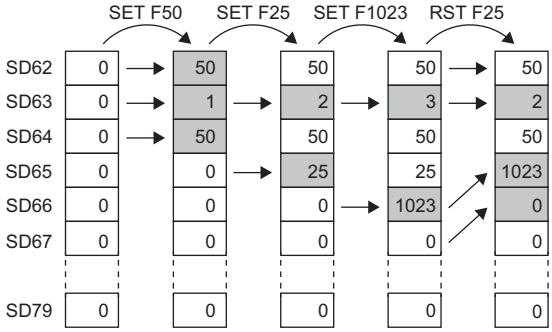
Point

Only one annunciator number is registered in the event history while power is turned on.

On/off method for annunciator

Annunciators are turned on by either the SET F□instruction or the OUT F□ instruction. Annunciators are turned off by the RST F□instruction or the LEDR instruction or the BKRST instruction.

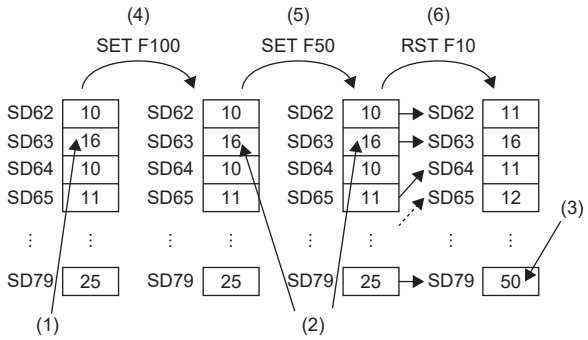
Point



When the annunciators are turned on/off using any methods (e.g. the MOV instruction) other than shown above, the operation is the same as that of internal relays. As a result, SM62 is not turned on and annunciator numbers are not stored into SD62 and SD64 (Table of detected annunciator numbers) to SD79.

■Operations when annunciators are turned on

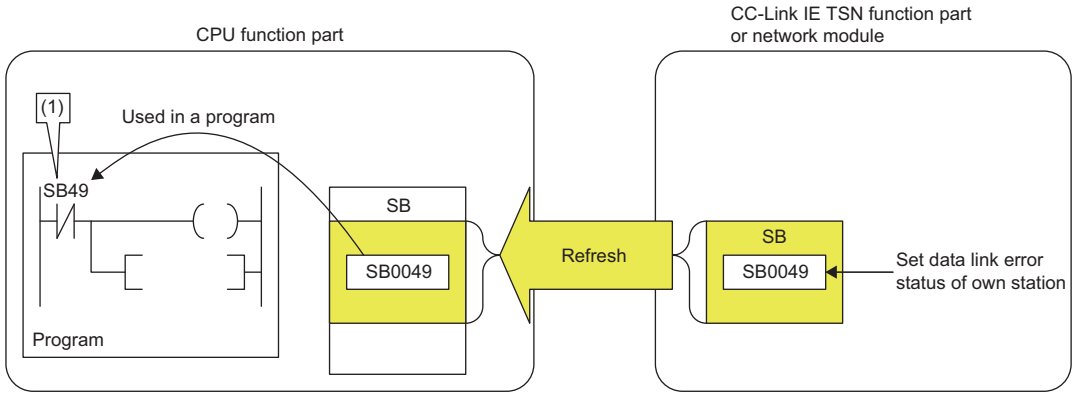
1. The annunciator numbers turned on are stored sequentially into SD64 to SD79.
2. The annunciator number stored into SD64 is stored into SD62.
3. SD63 value (Number of annunciators) is incremented by one.



■Operations when annunciators are turned off

1. The number of the annunciator deactivated is removed, and the numbers of annunciators, which were lined up behind the removed one, move forward one by one.
2. When the annunciator number stored into SD64 is turned off, the annunciator number newly stored into SD64 is stored into SD62.
3. The value of SD63 is decremented by one. When the SD63 value gets decremented to 0, SM62 is turned off.

Point



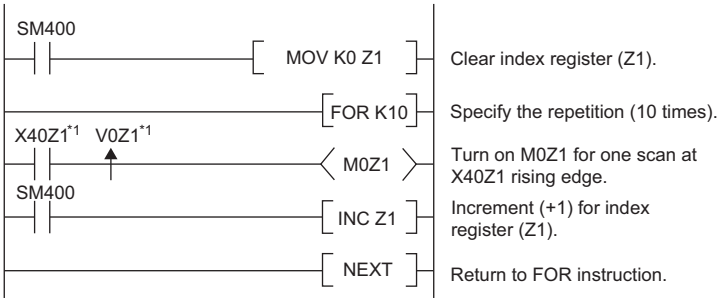
If more than 16 annunciators are turned on, the 17th annunciator onwards are not stored into SD64 to SD79. However, if the numbers of annunciators registered in SD64 to SD79 are turned off, the lowest numbers, which are not registered in SD62 to SD79, of the numbers of annunciators which were turned on for the 17th on and after, are stored into SD64 to SD79.

(1) Annunciators have been stored for the maximum number (16).
(2) Because annunciators have been stored for the maximum number, the value does not change.
(3) The smallest number is stored.
(4) Turn on the 17th device.
(5) Turn on the 18th device.
(6) Turn off the first device.

Link special relay (SB)

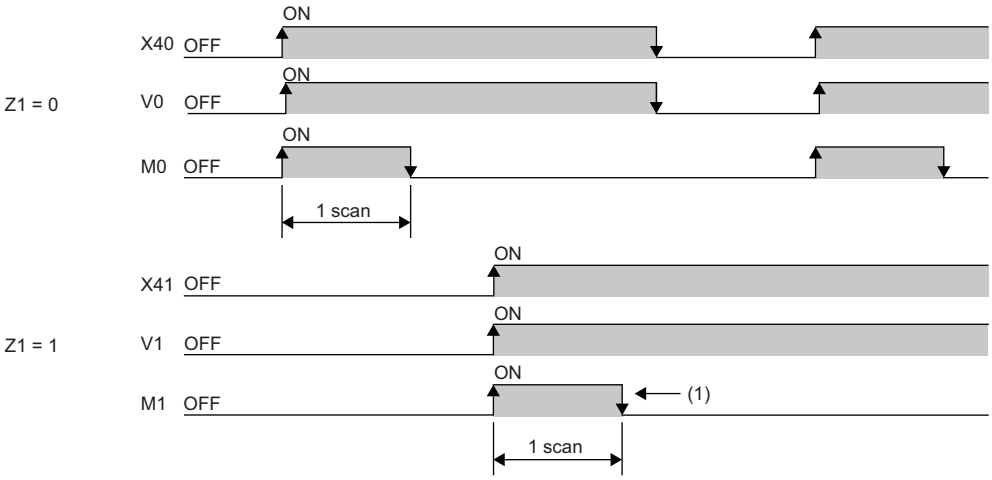
The communication status and error detection status of network modules are output to the link special relay (J□\SB□) on the network. The link special relay (SB) is a device for using as a refreshing target of link special relays in the network. The part which is not used for refreshing can be used for other applications.

(1) The network status is checked.



Point

For the link special relay assignment of the controller itself, refer to the following.



☞ Page 2013 List of Link Special Relay (SB)

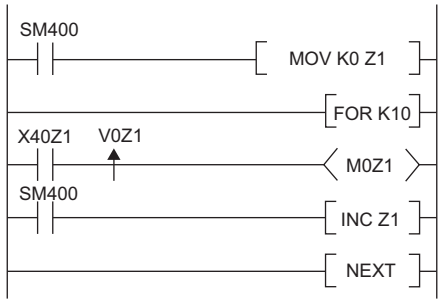
Edge relay (V)

The edge relay is a device that memorizes operation results (on/off information) from the head of the ladder block, allowing its use only by the EGP/EGF instruction. This device is executed for various objectives such as the rising (off and on) detection in the structured programs by the index modification.

*1 Edge relay V0Z1 memorizes on/off information of X0Z1.

(1) When X41 is rising, this device is turned on for one scan duration.

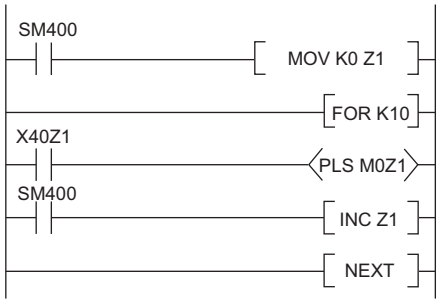
Precautions



■Index modification by the edge relay (V) between FOR and NEXT instructions

Between the FOR instruction and the NEXT instruction, pulse output is provided through the edge relay (V).

However, pulse output by the PLS, PLF, or pulse conversion (□P) instruction is not available.

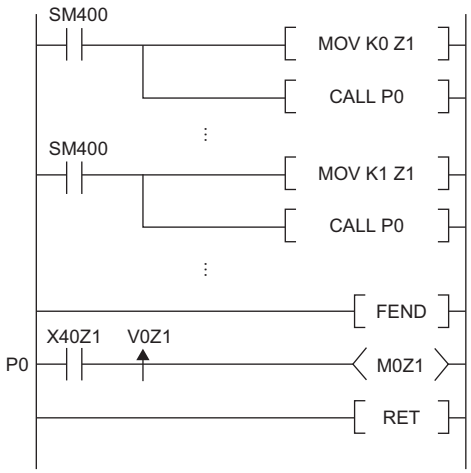


When edge relay is used

Pulse output of M0Z1 is provided normally.

When edge relay is not used

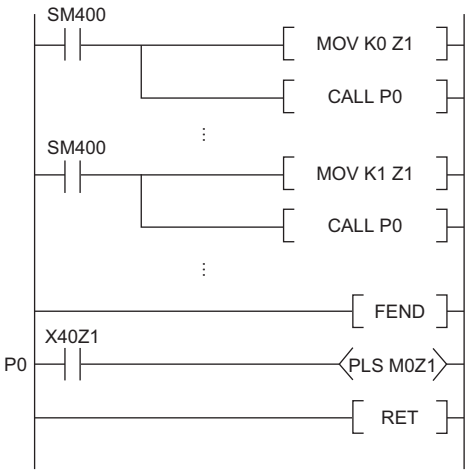
Pulse output of M0Z1 is not provided normally.



■Index modification by the edge relay (V) with CALL instruction

In the CALL instruction, pulse output is provided through the edge relay (V).

However, pulse output by the PLS, PLF, or pulse conversion (□P) instruction is not available.



When edge relay is used

Pulse output of M0Z1 is provided normally.

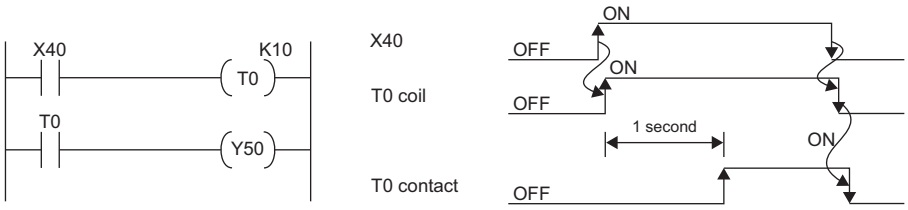
When edge relay is not used

Pulse output of M0Z1 is not provided normally.

Timer

This device starts measurement when the timer coil is turned on. When the current value reaches a setting value, time is up and the contact is turned on. This timer is an up-timing type device and therefore the current value matches a setting value when the timer time is up.

Types of timers



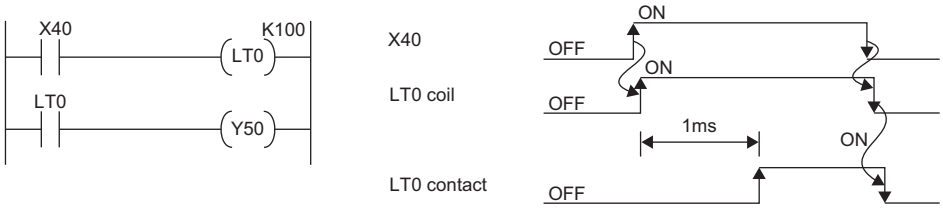
There are two types of timers: timer (T) which retains the current value in 16-bit units and long timer (LT) which retains it in 32-bit units. The timer (T) and the long timer (LT) are different devices and the number of device points can be set for each of them. In addition, there are the retentive timer (ST) and the long retentive timer (LST), both of which retain the current value even if the coil is turned off. *1

Type of timer			
Timer	Current value = 16 bits	Timer (T)	Low-speed timer
			High-speed timer
		Retentive timer (ST)	Low-speed retentive timer
			High-speed retentive timer
	Current value = 32 bits	Long timer (LT)	
		Long retentive timer (LST)	

*1 For the timer (T)/long timer (LT), the current value returns to 0 when the coil is turned off.

■Timer (T)

This device starts measurement when the coil of the timer is turned on. When the timer current value matches a setting value, time is up and the timer contact is turned on. When the timer coil is turned off, the current value returns to 0 and the timer contact is turned off.



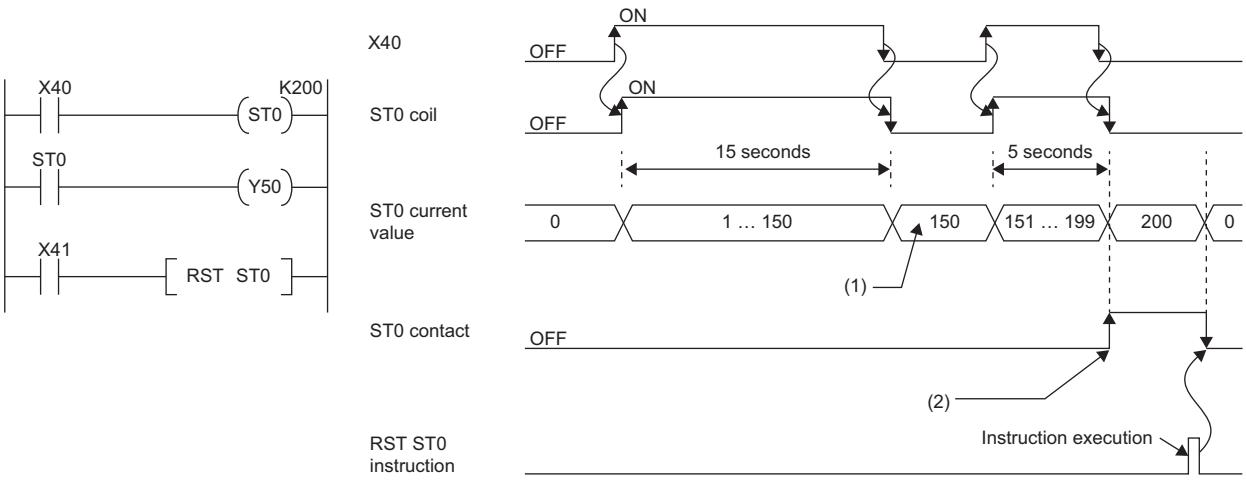
This figure shows the example when the timer time limit value is 100ms.

■Long timer (LT)

This device can count from 0 to 4294967295 to measure the time. If the measuring unit is set to 0.01ms, the measurable time range of this device is from 0 to about 11.9 hours. The current value of the long timers is updated by adding a difference of the counter which is used in the system when the OUT LT☐ instruction is executed. Proper time can be measured even when the coil instruction of the long timer cannot be executed once per scanning because the counters used in the system count asynchronously with scanning.

When the long timer coil is turned on, measurement starts and when the long timer current value matches a setting value, time is up and the long timer contact is turned on. When the long timer coil is turned off, the current value returns to 0 and the long timer contact is turned off.

This figure shows the example when the long timer time limit value is 0.01ms.



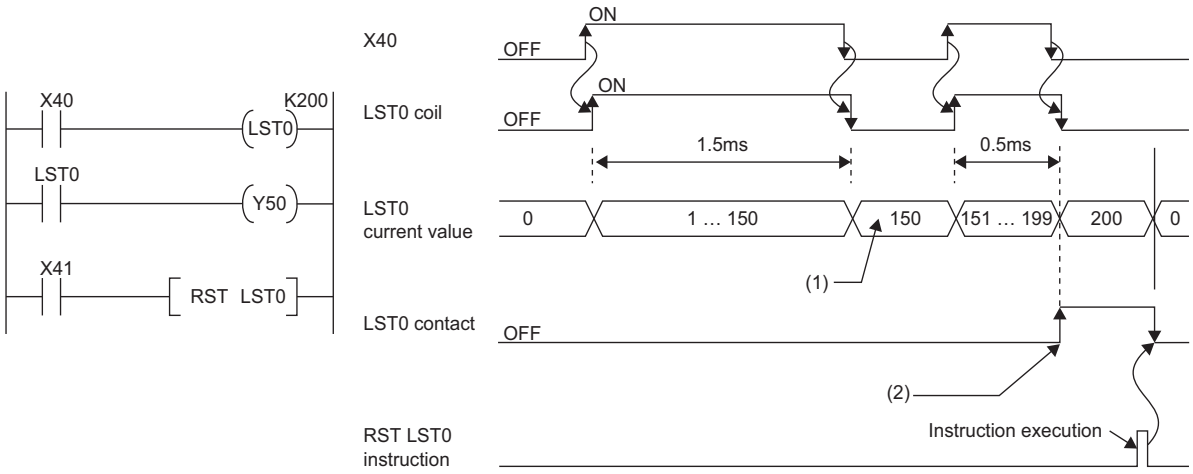
The long timer contact is turned on at the following coil execution after the long timer coil is turned off and on. The long timer contact is not turned on simultaneously when the long timer coil is turned off and on.

Point

The long timer (LT) can be used in interrupt programs. (☞ Page 261 Interrupt Program)

■Retentive timer (ST)

This device counts the sum of time duration in which the coil is turned on. When the retentive timer coil is turned on, measurement starts and when the timer current value matches a setting value (when time is up), the retentive timer contact is turned on. The current value and the contact on/off state is retained even when the retentive timer coil is turned off. When the coil is turned on again, measurement starts with the retained current value. To clear the retentive timer current value and turn off the contact, issue the RST ST☐ instruction.



This figure shows the example when the retentive timer time limit value is 100ms.

(1) Even though the ST0 coil turns off, the current value is held.

(2) Even though the ST0 coil turns off, the contact remains on.

■Long retentive timer (LST)

This device counts the sum of time duration in which the coil is turned on. When the long retentive timer coil is turned on, measurement starts and when the timer current value matches a setting value (when time is up), the contact is turned on. The current value and the contact on/off state is retained even when the long retentive timer coil is turned off. When the coil is turned on again, measurement starts with the retained current value. To clear the long retentive timer current value and turn off the contact, issue the RST LST☐ instruction.

This figure shows the example when the long retentive timer time limit value is 0.01ms.

(1) Even though the coil turns off, the current value is held.

(2) Even though the coil turns off, the contact remains on.

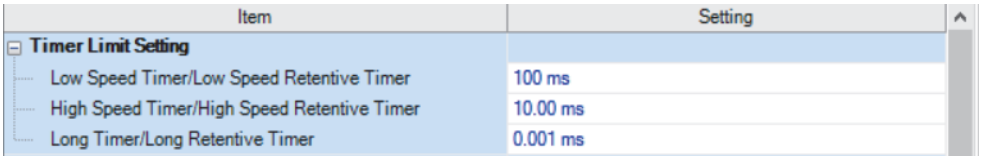
Point

The long retentive timer (LST) can be used in interrupt programs. (☞ Page 261 Interrupt Program)

■Low-speed/high-speed timer (T/ST)

The low-speed timer and high-speed timer are the same device which is set to a low speed or high speed timer by writing the instruction accordingly to specify it on the timer. For example, specifying OUT T0 generates a low-speed timer and specifying OUTH T0 produces a high-speed timer even when using the same T0 device. This also applies to the retentive timer.

Timer time limit value



Although the low-speed timer and high-speed timer are the same device, timer limit value are different depending on how to specify the timer device (how to write the instruction). For example, specifying OUT T0 generates a low-speed timer and specifying OUT H T0 produces a high-speed timer even when using the same T0 device. This also applies to the retentive timer. The long timer cannot be set to a low-speed or high speed device. The time limit value for each timer is set in "Timer Limit Setting".

■Timer limit setting

The following window is to set the timer time limit values.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Operation Related Setting] ⇨ [Timer Limit Setting]

Window

Displayed items

Item	Description	Setting range	Default
Low Speed Timer/Low Speed Retentive Timer	Set the timer time limit value of T and ST used for the low-speed timer and low-speed retentive timer.	1 to 10000ms (unit: 1ms)	100ms
High Speed Timer/High Speed Retentive Timer	Set the timer time limit value of T and ST used for the high-speed timer and high-speed retentive timer.	0.01 to 100ms (unit: 0.01ms)	10.00ms
Long Timer/Long Retentive Timer	Set the timer time limit value of LT and LST used for the long timer and long retentive timer.	0.001 to 1000ms (unit: 0.001ms)	0.001ms

Timer current value and the measurable range

This sections describes the timer current value and the measurable range.

■Timer (T/ST)

The current value range is 0 to 65535. The measurable time range is from 0 to (timer time limit value × 65535).

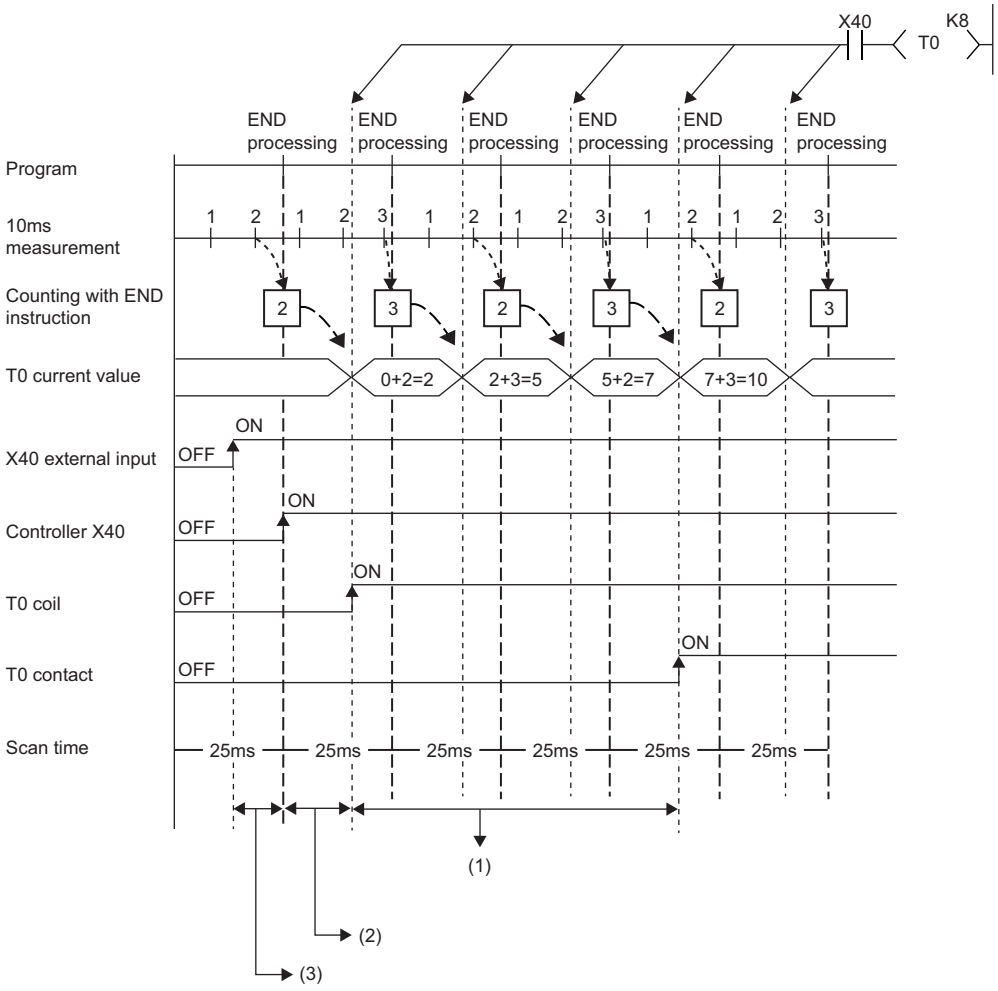
■Long timer (LT/LST)

The setting range of the current value is 0 to 4294967295, which is the same as the range of unsigned 32-bit integers. The measurable time range is from long timer time limit value to (timer time limit value × 4294967295).

Handling timers

When executing the timer coil (the OUT T☐ instruction), the timer coil is turned on/off, the current value is updated, and the contact is turned on/off.

Accuracy of timers

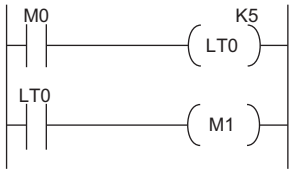


This sections describes the accuracy of timers.

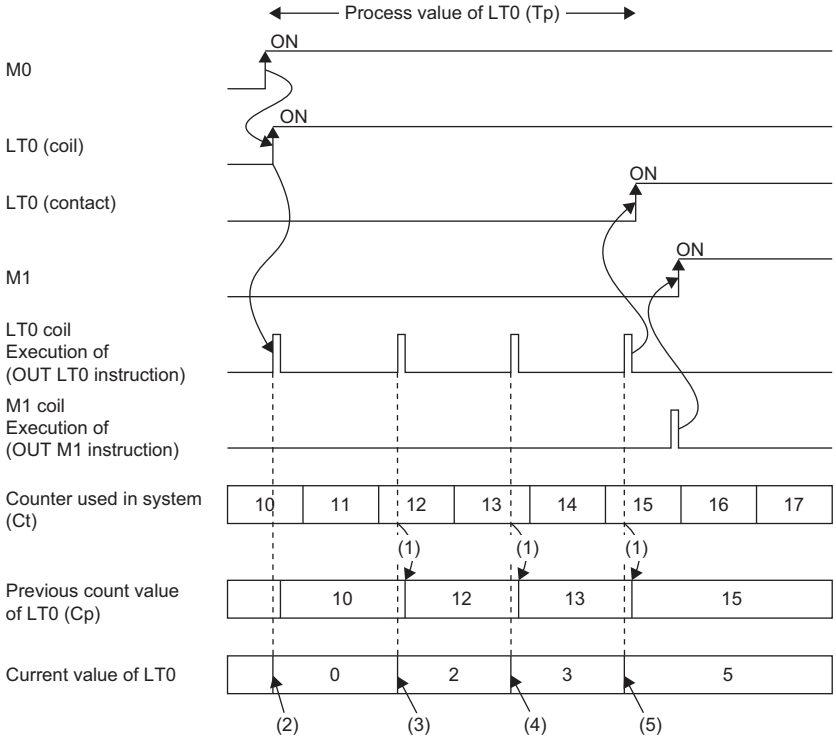
■Timer (T/ST)

The scan time value measured by the END instruction is added to the current value when the OUT T☐ instruction is executed. If the timer coil is turned off when the OUT T☐ instruction is executed, the current value is not updated. The maximum response accuracy of the timer (the time duration from capture of an input (X) to output of it) is "2 scan time + timer time limit setting".

Ex.



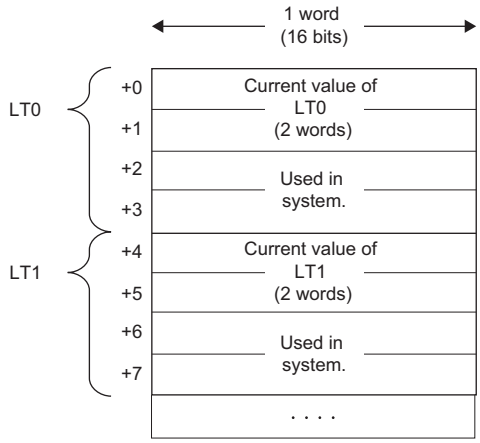
Timer limit setting = 10ms, setting value of T0 = 8 (10ms × 8 = 80ms), scan time = 25ms



(1) Accuracy from when the coil of the timer turns on until when the contact of the timer turns on - (1 scan time + Timer limit setting) to (1 scan time)
(2) Timing on when the coil of the timer turns on
(3) Input fetching timing

■Long timer (LT/LST)

In the following program, the accuracy of Tp (the time duration from the long timer coil activation to long timer contact activation) is (Ts-Tu) ≤ Tp < (Ts + Tu).



(1) Cp is updated.
(2) LT0 is initialized to 0.
(3) The result of (Ct - Cp) is added.: 0 + (12 - 10) = 2
(4) The result of (Ct - Cp) is added.: 2 + (13 - 12) = 3
(5) The result of (Ct - Cp) is added.: 3 + (15 - 13) = 5
Tp: time duration from the long timer coil activation to long timer contact activation
Ts: setting value of the long timer
Tu: time limit value of the long timer

Data configuration of long timer (LT/LST)

The long timer (LT) and the long retentive timer (LST) use four words (64 bits) for each point. If the most significant two words are changed in a program, it is impossible to measure the time properly, because they are used by the system.

Point

The current value of the long timer (LT) and the long retentive timer (LST) is 32-bit data. It can be specified by the instructions which can specify signed or unsigned 32 bit data. (It cannot be specified with the BK + Instruction.)

Precautions

This section describes the precautions when using the timer and long timer.

■Precautions about timer usage

- Do not describe more than one coil (the OUT T☐ instruction) on the same timer during a single scanning. Doing so results in improper measurement because the timer current value is updated when the coil for each timer is executed.
- When timer is not used for data collection for each scan: While the coil on a timer (e.g. T1) is turned on, the timer coil (the OUT T☐ instruction) cannot be skipped by the instructions such as the CJ. When the timer coil is skipped, proper measurement is impossible because the timer current value is not updated. In addition, when the timer exists in a subroutine program, be sure to execute a subroutine call including T1 coil only once for each scanning operation while the coil of the timer (e.g. T1) is turned on. Otherwise proper measurement is impossible.
- The timer cannot be used in the initial execution type program, the fixed scan execution type program, or the event execution type program where the occurrence of an interrupt is set to be a trigger. The timer can be used in standby type programs if the coil of timer (OUT T☐ instruction) is executed one time for one scan using a subroutine program.
- The timer cannot be used in interrupt programs. The timer can be used in subroutine programs or FB programs if the coil of timer (OUT T☐ instruction) is executed one time for one scan.
- When setting value is 0: The contact is turned on when the OUT T☐ instruction is executed.
- Even when the setting value is increased after the timer time is up, the timer status does not change (time continues to be up) and the timer does not operate.

■Precautions about long timer usage

This section describes the precautions when using long timers (LT/LST).

- The long timer cannot be used in initial execution type programs.
- Even when the setting value is increased after the long timer time is up, the long timer status does not change (time continues to be up) and the long timer does not operate.

■Timer setting value and timer limit setting

When the condition is "Timer setting value < Scan time + Timer limit setting", the coil and the contact may be turned on at the same time depending on the timing when the coil turns on. When the condition is not satisfied, reduce the timer limit setting value to satisfy the condition.

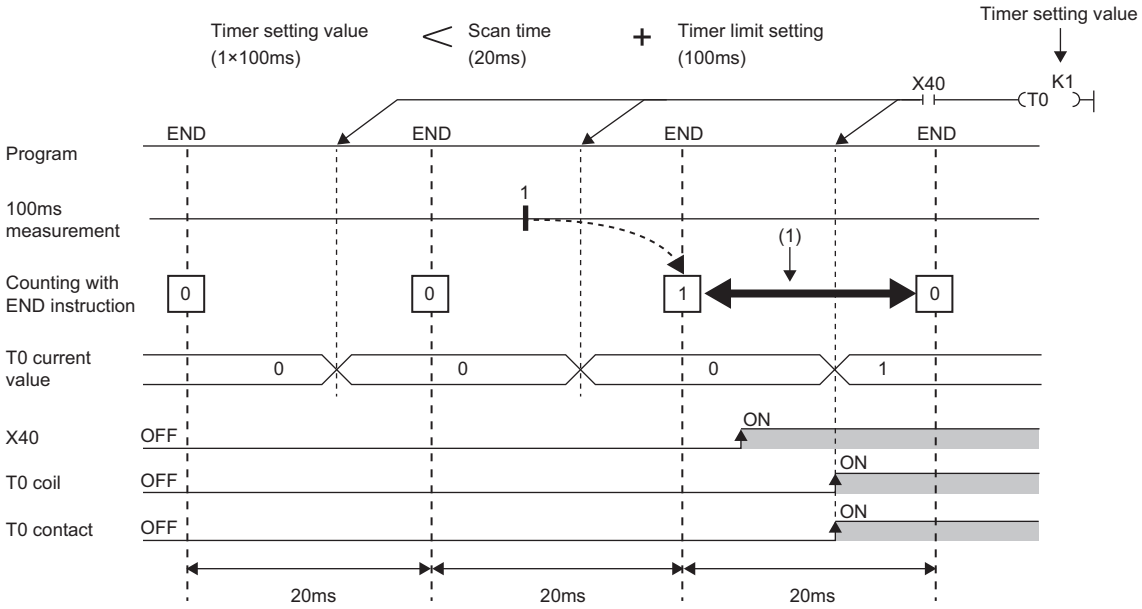
Ex.

When changing the low-speed timer to high-speed timer and reducing the timer limit setting value (scan time: 20ms)

Before change (low-speed timer)

■Timer limit setting
Low Speed Timer/Low Speed Retentive Timer: 100ms
Timer setting value (100ms × 1 = 100ms) < Scan time (20ms) + Timer limit setting (100ms)

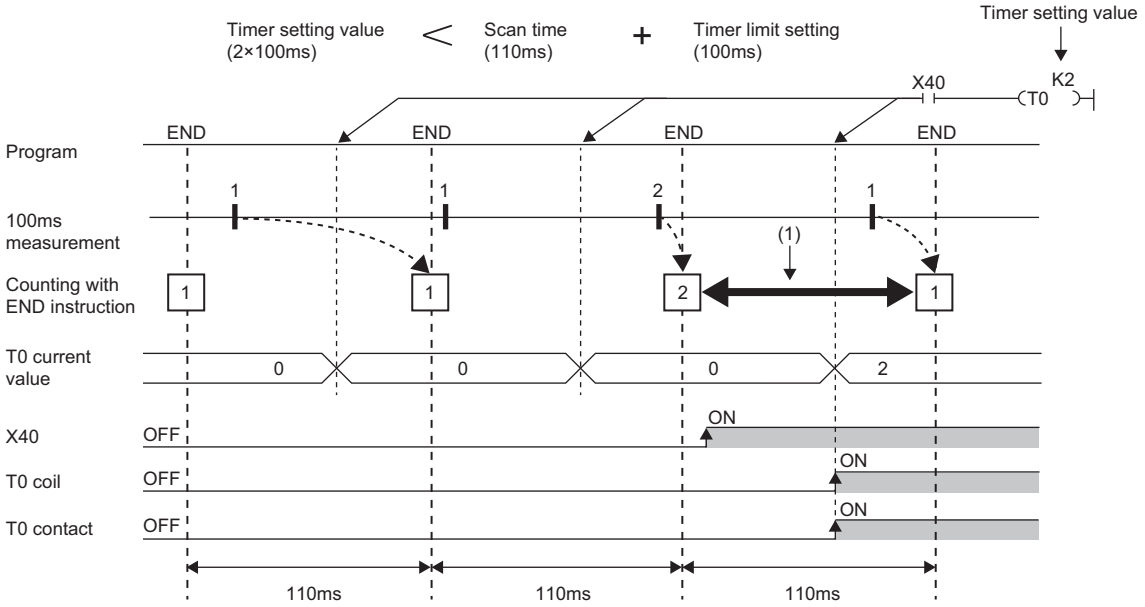
After change (high-speed timer)



■Timer limit setting
High Speed Timer/High Speed Retentive Timer: 10.00ms
Timer setting value (10.00ms × 10 = 100ms) ≥ Scan time (20ms) + Timer limit setting (10ms)

The following shows an example of when the coil and the contact are turned on at the same time when the condition is "Timer setting value < Scan time + Timer limit setting".

Ex.



In the case where the values are set as follows (timer setting value: 1 (1 × 100ms), scan time: 20ms, and timer limit setting: 100ms), when the coil of the timer (T0) turns on in the next scan after the coefficient of the END instruction becomes equal to or higher than the timer setting value, the coil and the contact turn on at the same time because the timer current value becomes equal to the timer setting value at startup of the timer.

(1) The coefficient of the END instruction becomes equal to or higher than the timer setting value. Therefore, when the coil turns on during this period, the contact also turns on at the same time.

Ex.

In the case where the values are set as follows (timer setting value: 2 (2 × 100ms), scan time: 110ms, and timer limit setting: 100ms), when the coil of the timer (T0) turns on in the next scan after the coefficient of the END instruction becomes equal to or higher than the timer setting value, the coil and the contact turn on at the same time because the timer current value becomes equal to the timer setting value at startup of the timer.

(1) The coefficient of the END instruction becomes equal to or higher than the timer setting value. Therefore, when the coil turns on during this period, the contact also turns on at the same time.

Counter

This device counts the number of rising operation of the input condition in the program. The counter is an up-timing type device and therefore when the count value matches a setting value, the counter counts up and the contact is turned on.

Types of counters

There are two types of counters: counter (C) which retains the counter values in 16-bit units and long counter (LC) which retains them in 32-bit units. The counter (C) and the long counter (LC) are different devices and the number of device points can be set for each of them.

■Counter (C)

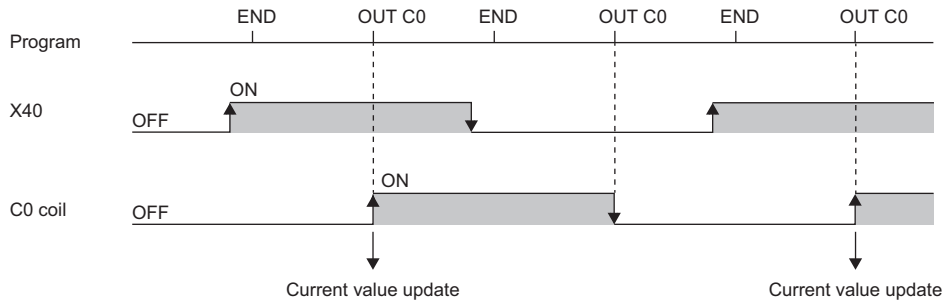
This device uses one word for each point. The measurable range is 0 to 65535.

■Long counter (LC)

This device uses two words for each point. The measurable range is 0 to 4294967295.

Point

The long counter (LC) can be used in interrupt programs. (☞ Page 261 Interrupt Program)

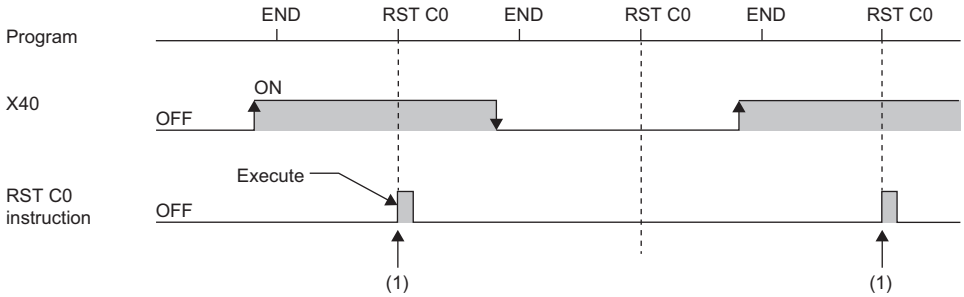


Counting process

When executing the counter coil (OUT C☐instruction / OUT LC☐instruction), the counter coil is turned on/off, the current value is updated (count value +1), and the contact is turned on/off. The current value is updated (count value +1), when the counter coil input is rising (off and on). The current value is not updated when the coil input is turned off, on and on, and on and off.

[Ladder example]

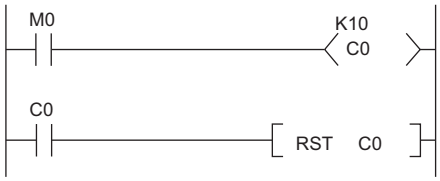
[Current value update timing]



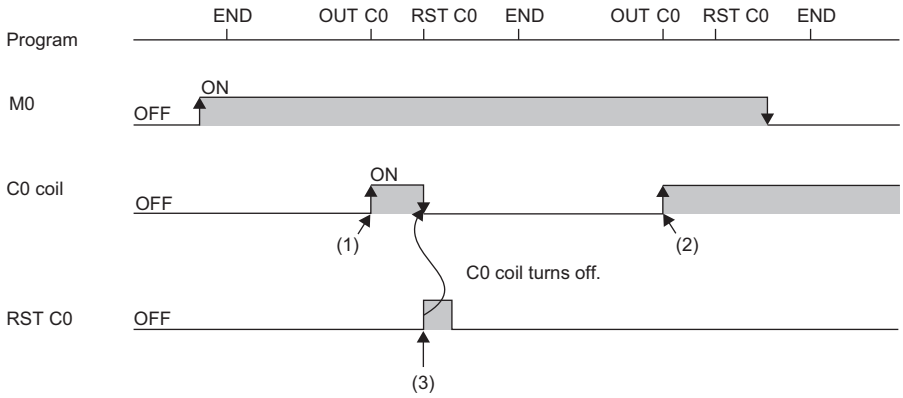
Resetting counters

The counter current value is not cleared even when the counter coil input is turned off. To clear the counter current value (resetting) and turn off the contact, issue the RST C☐/RST LC☐ instruction. When executing the RST C☐ instruction, the counter value is cleared and the contact is turned off.

[Ladder example]



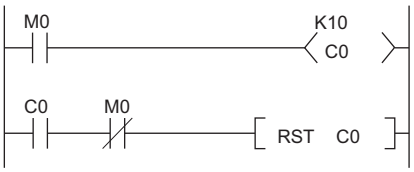
[Counter reset timing]



(1) The count value is cleared, and the contact turns off.

■Precautions about counter reset

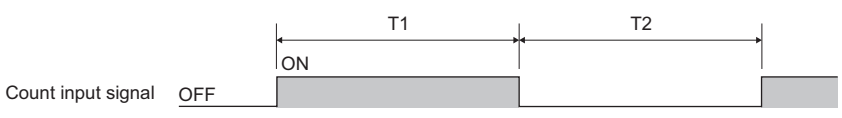
When executing the RST C☐ instruction, the coil for C☐ is also turned off. If the execution condition for the OUT C☐ instruction is turned on after the RST C☐ instruction is executed, the coil of C☐ is turned on and the current value is updated (count value +1) when the OUT C☐ instruction is executed.



In the above ladder example, the coil of C0 is turned on by turning off and on M0 and as a result the current value is updated. When C0 counts up, C0 contact is turned on and C0 current value is cleared by execution of the RST C0 instruction. At this time C0 coil is also turned off. When M0 is turned on at the next scanning, the current value is updated because C0 coil is turned off and on during the OUT C0 instruction execution (the current value is changed to 1).

(1) The current value update contact turns on.
(2) The current value is updated because the coil of C0 turns on.
(3) The count value is cleared, and the contact turns off.

To address the above problem, insert a normally closed contact of the execution condition for the OUT C0 instruction into the execution condition for the RST C0 instruction to prevent C0 coil from being turned off while the execution condition (M0) of the OUT C0 instruction is turned on as shown in the following ladder example.



Maximum counting speed for counters

Counting is possible only when on/off time of the input condition is longer than the execution interval of the same OUT C☐ instruction. Maximum counting speed for counters can be obtained by the following equation:

$$\text{Maximum counting speed Cmax} = \frac{n}{100} \times \frac{1}{T} \text{ [times/s]}$$

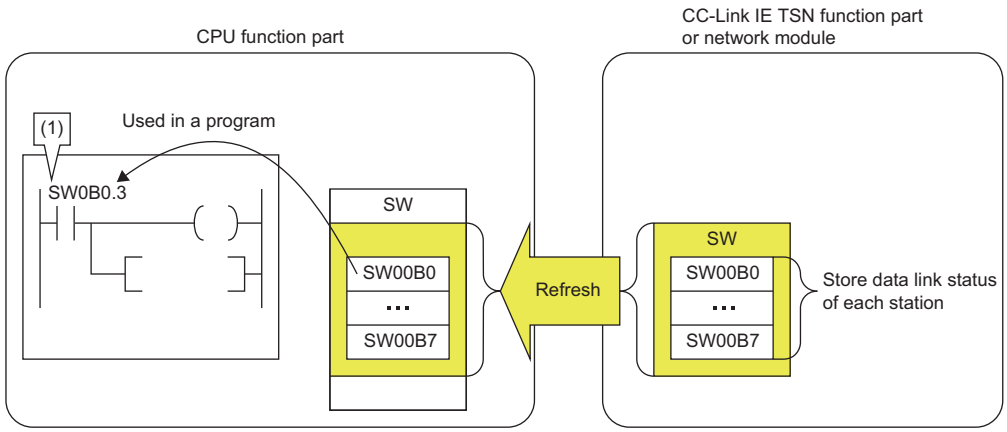
*1 Duty (n) is a value which expresses the ratio of on/off time of the count input signal as a percent (%) value.

- When $T1 \geq T2$, $n = \frac{T2}{T1+T2} \times 100\%$
- When $T1 < T2$, $n = \frac{T1}{T1+T2} \times 100\%$

Data register (D)

This device can store numerical values.

Link register (W)



This device is used as a controller side device when refreshing word data between the network module and the controller.

Refreshing network modules using link register

Data are transferred/received between the link relay (W) within the controller and the link register (LW) of the network module. The refresh range is specified using parameters on the network module. The part which is not used for refreshing can be used for other applications.

Link special register (SW)

Word data information on the communication status and error detection status of a network are output into the link special register (J□\SW□) on the network. The link special register (SW) is a device for using as a refreshing target of link special registers in the network. The part which is not used for refreshing can be used for other applications.

(1) The network status is checked.

Point

For the link special register assignment of the controller itself, refer to the following.

Page 2017 List of Link Special Register (SW)

18.4 System Device

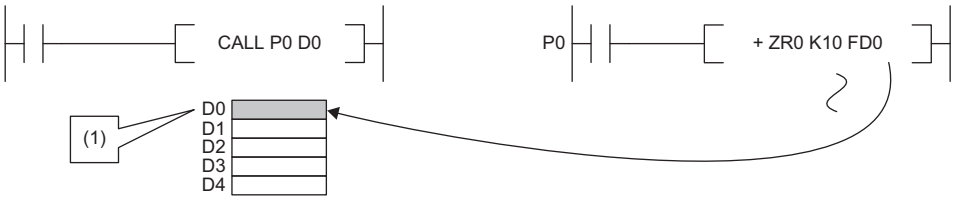
The system device is used by the system. Assignment/capacity is fixed and cannot optionally be altered.

Function device (FX/FY/FD)

This device is used for the subroutine programs with argument passing. Data is written/read between the subroutine call sources with argument passing and the subroutine programs with argument passing. When using the function device in a subroutine program, the device used in each subroutine program call source can be determined. As a result, when using the same subroutine program, it can be used without being aware of the call source of other subroutine programs.

Function input (FX)

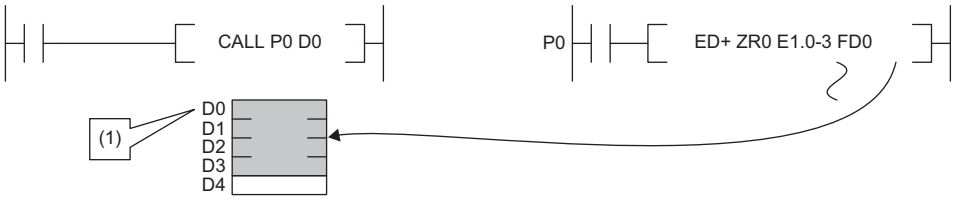
This device is used when passing on/off data to a subroutine program. In the subroutine program, bit data specified in a subroutine call instruction with argument passing are captured and used for operation. All the bit data specification devices of the controller are available.



Function output (FY)

This device is used when passing operation results (on/off data) in a subroutine program to a subroutine program call source. Operation results are stored into the device specified in the subroutine program with argument passing. All the bit data specification devices except controller input (X) are available.

Function register (FD)



This device is used for writing/reading between the subroutine call source and the subroutine program. The input/output condition of the function register is automatically identified by the controller. "Source data" in a subroutine program means data input into the subroutine program. "Destination data" in a subroutine program means data output from the subroutine program. One point of a function register occupies maximum of four words and can store 16-bit data, 32-bit data, 64-bit data, single-precision real number, and double-precision real number. However the number of words to be used depends on the instruction in the subroutine program.

For example, for the destination of addition instruction (+instruction) of 16-bit signed integer, one word is used.

(1) The data is stored in one point of D0.

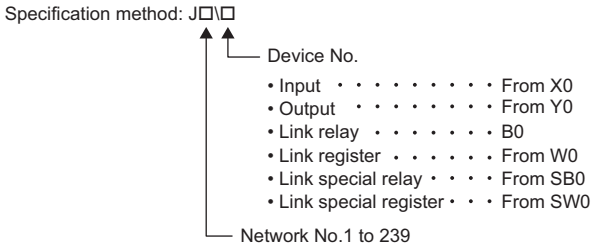
Besides, for the destination of addition instruction (ED+instruction) of double-precision real number, four words are used.

(1) The data is stored in four points of D0 to D3.

Special relay (SM)

This is the internal relay for which the specification is defined in the controller, where the status of the controller is stored. (☞ Page 1949 List of Special Relay (SM) Areas)

Special register (SD)



This is the internal register for which the specification is defined in the controller, where the status of the controller (such as diagnostics information and system information) is stored. (☞ Page 1968 List of Special Register (SD) Areas)

18.5 Link Direct Device

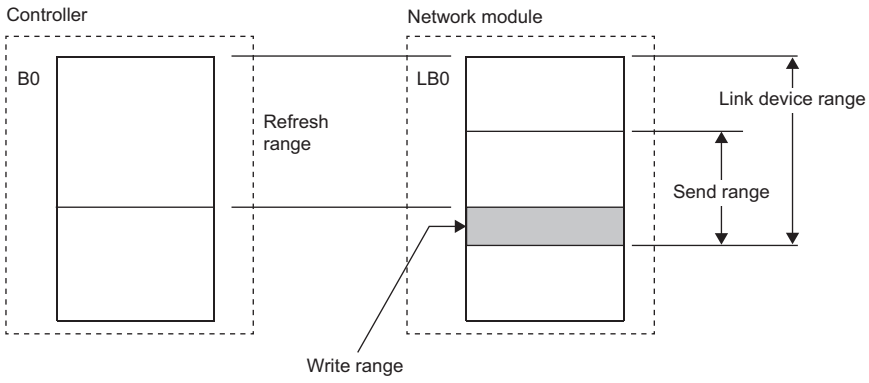
This device directly accesses link relays and/or link registers of the network module.

Specification method

Specify a link direct device as shown below: The link register 10 (W10) of the network number 2 can be specified as "J2\W10".

Point

For bit devices, digit specification is allowed. (Example: J1\K1X0, J10\K4B0)



Specification range

All the link devices of the network module can be specified. The link devices which fall outside the range specified with "Refresh Setting" can also be specified.

Specification range for writing

Writing should be done for the range which is within the link device range specified as a sending range of network parameters and outside the range specified as a refresh range for "Refresh Setting". *1

Note that writing in the range specified as the refresh range overwrites link device data of the network module during refresh process. When writing data to a writing range of another station using the link direct device, data is overwritten with received data during data reception from another station.

*1 There is only one network module to which the link direct device can write data for each network number. When more than one network module with the same network number is mounted, the network module with the lowest slot number is the target for writing by the link direct device.

Specification range for reading

Data can be read from all the range of link devices of the network module.

Difference from link refresh

The following table shows the difference between the link direct device and link refresh.

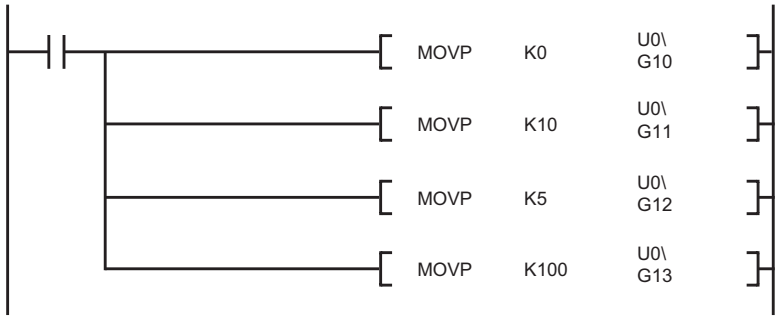
Item		Link direct device	Link refresh
Description method in program	Input	Jn\K4X0...	X0...
	Output	Jn\K4Y0...	Y0...
	Link relay	Jn\K4B0...	B0...
	Link register	Jn\W0...	W0...
	Link special relay	Jn\K4SB0...	SB0... Or module label
	Link special register	Jn\SW0...	SW0... Or module label
Access range in relation to network module		All the link devices for each network module	The range specified in "Refresh Setting"
Guarantee range of access data		In word (16-bit) units	In word (16-bit) units

How to access CC-Link IE TSN link device

CC-Link IE TSN link devices can be accessed using link direct devices.
However, the link device assigned to the synchronous station cannot be accessed using the link direct device. Make refresh settings for the same link device and access the refresh target device or label.

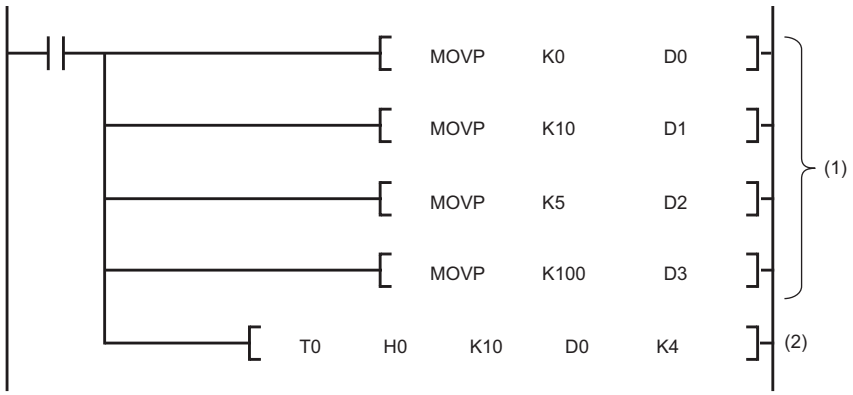
18.6 Module Access Device

This device directly accesses from the controller to the buffer memory of the intelligent function module mounted on the main base unit and extension base unit.



Specify this device with 'Un\Gn'. (Example: U5\G11)

Specified item		Value to be specified
Un	Start I/O number of intelligent function modules	Upper two digits when a start I/O number is described in three digits (00H to FFH) Example: 4F stands for X/Y4F0
Gn	Buffer memory address	0 to 268435455 (decimal)



Point

When reading/writing the buffer memory data using the module access device twice or more within a program, the processing speed can be increased by conducting read/write operations at a single point of the program using the FROM/TO instruction.

• When data is written using more than one module access device:

• When data is written at a single point of the program using the TO instruction:

(1) Store data to devices such as the data register (D).

(2) Write data to only one point in the program.

Buffer memory specification method

Specify this device with Un\Gn. The following lists specification examples of the buffer memory areas.

Buffer memory			Specification example
CPU function part (start I/O number: 3E0)		Communication speed setting (G82)	U3E0\G82
		Connection No.1 latest error code (G130)	U3E0\G130
CC-Link IE TSN function part (start I/O number: 00)*1		Remote input (RX) (G57344 to G58367)	U00\G57344 to U00\G58367
		Initial status (G6291480)	U00\G6291480
Motion function part (start I/O number: 02)*1		Accessibility to labels for motion function (G14032767.0)	U02\G14032767.0
Intelligent function module	RJ71GP21-SX (start I/O number: 04)	Number of transient transmission errors (G2592)	U04\G2592
	R60AD4 (start I/O number: 06)	Latest alarm code (G2)	U06\G2

*1 When the start I/O number is changed, the start number is also changed.

How to access CC-Link IE TSN link device

CC-Link IE TSN link devices are allocated in the buffer memory area of the controller and can be accessed via the module access device.

However, the link device assigned to the synchronous station cannot be accessed via the module access device. Make refresh settings for the same link device and access the refresh target device or label.

Precautions

The following describes the precautions for when the module access device is used.

- If data is written to the refresh-target memory using a program while the refresh function is being used, the controller overwrites the data in the target memory at the execution of the refresh function. Thus, the expected operation may not be acquired. When the refresh function is used, do not write the data directly to the refresh-target memory but write it to the refresh-source memory.

*1 When the data is transferred from the controller to the module, the target memory is the buffer memory or link device. When the data is transferred from the module to the controller, the target memory is the specified device of the controller.

18.7 CPU Buffer Memory Access Device

This device accesses memory used by the built-in functions of the controller such the Ethernet function. (☞ Page 2028 List of buffer memory addresses)

Buffer memory specification method

Specify this device with Un\Gn. For details, refer to the following.

☞ Page 374 Buffer memory specification method

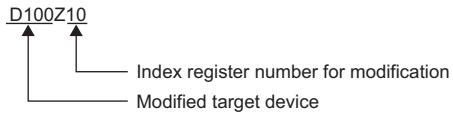
How to access CC-Link IE TSN link device

CC-Link IE TSN link devices are allocated in the buffer memory area of the controller and can be accessed via the CPU buffer memory access device.

However, the link device assigned to the synchronous station cannot be accessed via the CPU buffer memory access device. Make refresh settings for the same link device and access the refresh target device or label.

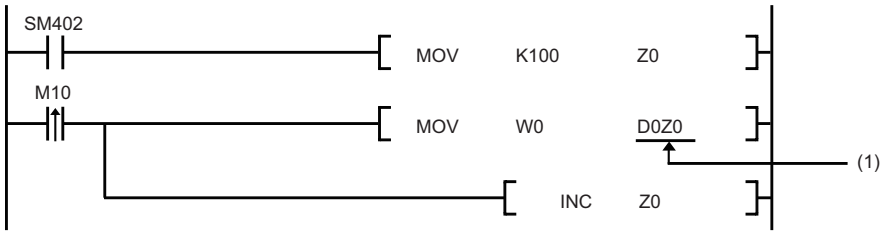
Point

For the buffer memory assignment of the controller itself, refer to the following.



☞ Page 2028 Buffer Memory

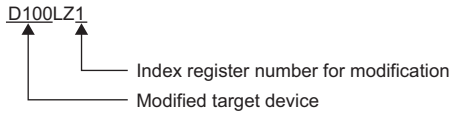
18.8 Index Register (Z/LZ)



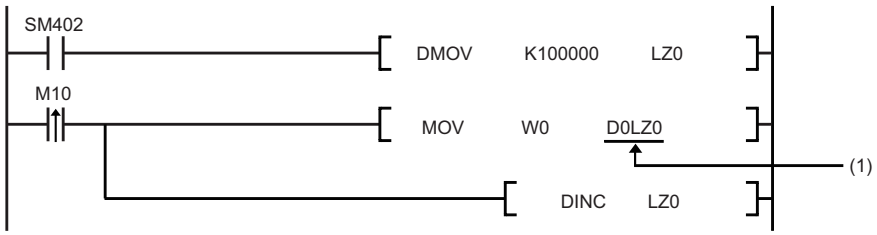
This device is used for the index modification of the device. The index modification is the indirect specification using the index register.
Specify the device with the number obtained from "Device number of device targeted for modification" + "Contents of index register".

16-bit index modification

The device number is modified using the index register (Z). The modification range for the device in the case of the 16-bit index modification is -32768 to 32767.



Ex.
Modifying D0 with Z0



(1) Access D0Z0 = D100.

32-bit index modification

The device number is modified using the long index register (LZ). The modification range for the device in the case of the 32-bit index modification is -2147483648 to 2147483647.

Ex.
Modifying D0 with LZ0

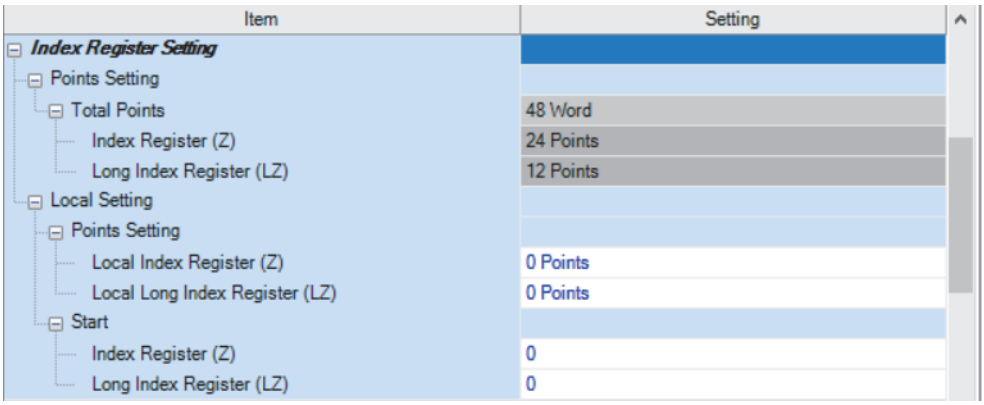
(1) Access D0LZ0 = D100000.

In addition, 32-bit index modification with ZZ expression using two index registers is also available.

Device for which index modification can be performed

The following table lists the devices that can be targeted for index modification.

Item	Description
16-bit index modification	X, DX, Y, DY, M, L, B, F, SB, V, T*1, LT*1, ST*1, LST*1, C*1, LC*1, D, W, SW, SM, SD, Jn\X, Jn\Y, Jn\B, Jn\SB, Jn\W, Jn\SW, Un\G, U3En\G, R, ZR, RD, P*3, I*3, J, U, K, H
32-bit index modification	M, B, SB, T*1, LT*1, ST*1, LST*1, C*1, LC*1, D, W, SW, Jn\B*2, Jn\W*2, Un\G*2, U3En\G*2, R, ZR, RD, K, H



*1 The devices can be used for the contact, coil and current value.
*2 For network numbers and the specification source of I/O numbers, 32-bit index modification cannot be performed.
*3 When the devices are used as a label, index modification cannot be performed.

Index register setting

The ranges to be used as a local device for the index register (Z) and long index register (LZ) are set.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Memory/Device Setting] ⇨ [Index Register Setting]

Window

Displayed items

Item			Description	Setting range	Default
Points Setting	Total Points		Check the total number of points for index register and long index register. The number of points is fixed at 48 words.	48 words (fixed)	48 words (fixed)
	Index Register (Z)		Check the number of points for index register. The number of points is fixed at 24 points.	24 points (fixed)	24 points (fixed)
	Long Index Register (LZ)		Check the number of points for long index register. The number of points is fixed at 12 points.	12 points (fixed)	12 points (fixed)
Local Setting	Points Setting	Local Index Register (Z)	Set the number of points for index registers used as a local device. Set within the range of the index register.	0 to 24 points (in one-point increments)	0 points
		Local Long Index Register (LZ)	Set the number of points for long index registers used as a local device. Set within the range of the long index register.	0 to 12 points (in one-point increments)	0 points
	Start	Index Register (Z)	Set the start number for the local index registers. Set within the range of the index register.	0 to 23	0
		Long Index Register (LZ)	Set the start number for the local long index registers. Set within the range of the long index register.	0 to 11	0

Combination of index modification

This section describes the combination of index modification.

Modification order for the device specification and index modification

According to the priority order shown below, the device specification (digit specification, bit specification, indirect specification) and index modification can be applied. However, some word devices may not follow the priority order shown below.

Order of priority	When the device targeted for the device specification and index modification is the bit device	When the device targeted for the device specification and index modification is the word device
High ↑ ↓ Low	1: Index modification 2: Digit specification	1: Index modification 2: Indirect specification 3: Bit specification

Specification method combined with device specification

The device targeted for specification is modified in order of: 1st modification, 2nd modification and then 3rd modification. Besides, the following contents can be used only for the device for which the 1st modification can be applied. (For example, index modification + digit specification is impossible for the function input (FX).)

Device targeted for specification	1st modification	2nd modification	3rd modification	Example
Bit device	Index modification	Digit specification	—	K4M100Z2
Word device	Index modification	Bit specification	—	D10Z2.0
	Index modification	Indirect specification	—	@D10Z2
	Bit specification	Index modification	—	D10.8Z2
	Indirect specification	Bit specification	—	@D10.8
	Index modification	Indirect specification	Bit specification	@D10Z2.8
	Indirect specification	Bit specification	Index modification	@D10.8Z2

Precautions

This section describes the precautions on using index modification.

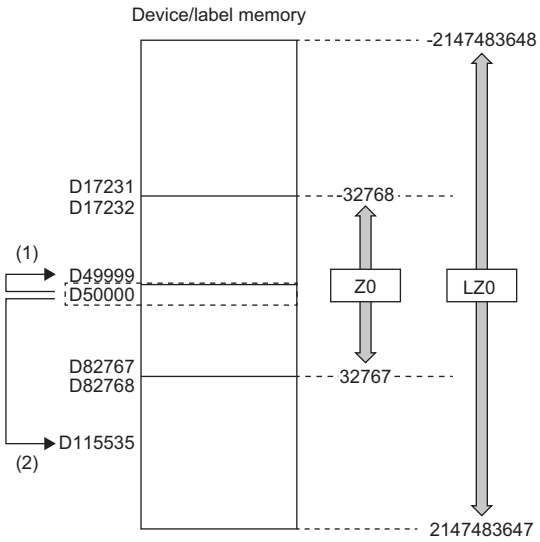
Device range check for index modification

For details on the device range check when index modification is performed, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

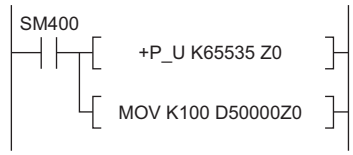
32-bit index modification (ZZ)

- To perform the 32-bit index modification specification with ZZ expression, review the range of the index register (Z). Note that the range within the LZ cannot be specified.
- For 32-bit index modification with ZZ expression, because the specified index register (Zn) and the immediately following index register (Zn+1) are used, caution must be taken to prevent duplicated index registers from being used.



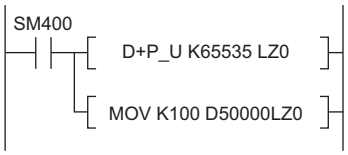
When values are stored in the index registers

For 16-bit index modification using the index register (Z), the range is -32768 to 32767.



Therefore, when values within the range from 32768 to 65535 are stored in the index register (Z) for an instruction which processes unsigned data, the instruction does not work in design because the range of the index modification will be -32768 to 32767. For the range of values larger than or equal to 32768, the long index register (LZ) must be used so that 32-bit-based index modification can be applied.

Ex.



Operation for Index modification

(1) When unexpected operation is executed

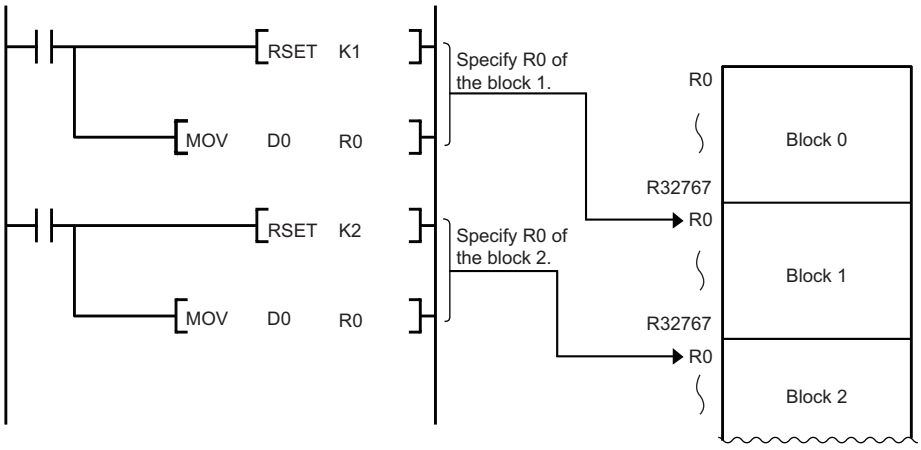
(2) When proper operation is executed

(1) When the value 65535 is stored in the index register (Z), D50000(-1) to D49999 are accessed because the value is turned into -1 when an index modification is performed.

(2) When a value larger than or equal to 32768 is used for an index modification, the value must be stored in the long index register (LZ). In doing so, the value 65535 is used as such for an index modification using the long index register (LZ) and D50000 (65535) to D115535 become accessible.

18.9 File Register (R/ZR)

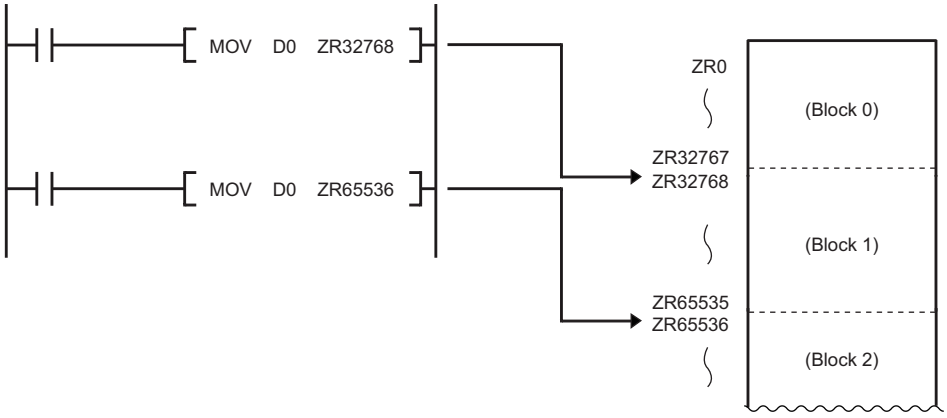
This device is a word device for extension. This device is specifically a file register file which exists in the file storage area on the device/label memory.



Specification method

There are two types of the specification methods for the file register: block switching and serial number methods.

Block switching method



In this method the number of points of file register being used is specified by being divided in increments of 32K point (R0 to R32767). When using more than one block, specification is conducted by switching to the block number used by the RSET instruction. "R" is used as the device symbol. The range of "R" is from R0 to R32767. However in the following cases the upper limit of the device number is "block size (unit: word) -1".

- The file register file size is smaller than 64K bytes.
- The file register file size is not a multiple of 64K bytes and the end block is specified in the RSET instruction.

Serial number method

In this method file registers having more than 32K points are specified using serial device numbers. File registers of the multiple blocks can be used as consecutive file registers. "ZR" is used as the device symbol. The range of ZR is from ZR0 to (file register file size (unit: word) -1).

Setting file registers

This section describes the settings required to use the file registers.

Configuration procedure

This section describes the procedure to use the file registers.

1. Set the file register usage with [CPU Parameter].
2. Create in advance the device memory which will become the file register file.

(GX Works3 Operating Manual)

3. When using the file registers, which are common for all programs, a file register file with the name and capacity set in the file register setting is created. *1

*1 If the capacity is not set (blank), a file register file is not created.

4. Write parameters and file register files into the controller.

File register setting

This setting must be completed before using the file registers.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [File Setting] ⇨ [File Register Setting]

Window

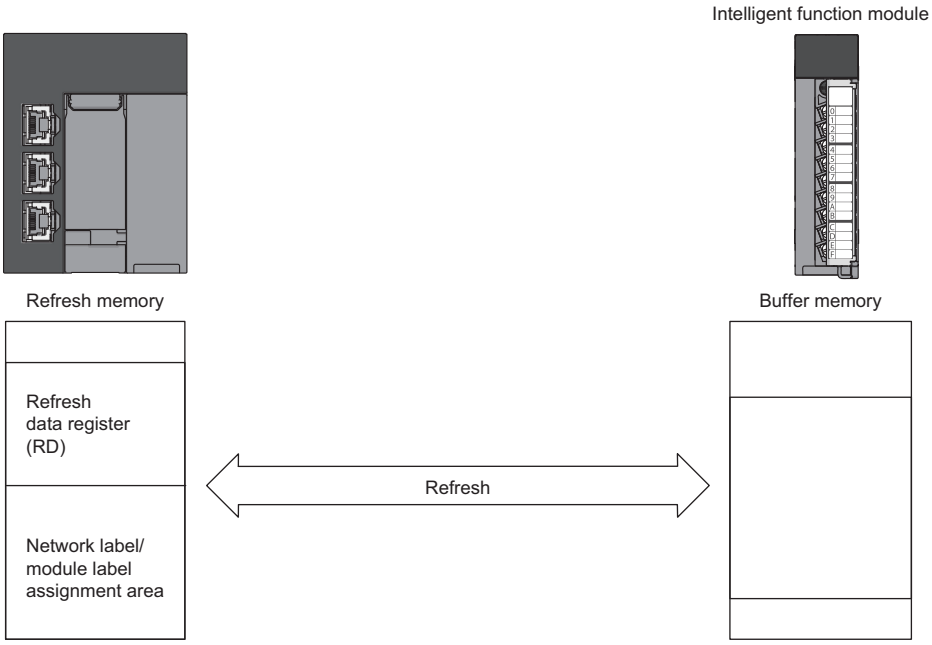
Displayed items

Item	Description	Setting range	Default
Use Or Not Setting	Specify whether or not file registers should be used.	• Not Use • Use Common File Register in All Programs	Not Use
Capacity	Specify the capacity of the file register in increments of 32K words when "Use Common File Register in All Programs" is selected.*1	• MXR500-128, MXR500-256: 10208K words maximum • MXR300-16, MXR300-32, MXR300-64: 8160K words maximum Specify the following range for the setting range. File register ≤ File storage area ≤ Maximum value	—
File Name	Assign a file name to the file register when "Use Common File Register in All Programs" is selected.	60 characters or less	—

*1 If the capacity is not set (blank), an error occurs at power-on or reset operation.

■Precautions

- When the capacity of the file register file setting is changed, the file capacity is changed to the changed size when the parameter is reflected. (If the size of the file register file that has already been written is smaller than the new parameter, it is extended, and if the size is larger, it is reduced.)

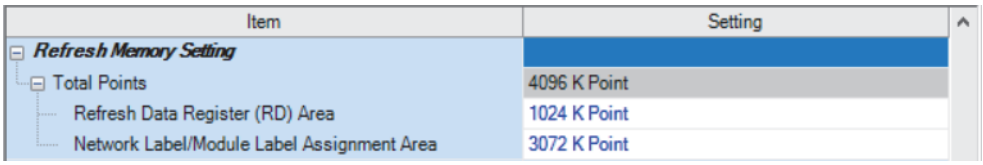


Clearing file registers

To clear the file registers, use the following methods (☞ Page 332 Memory Operation)

- Clearing in the program: write 0 into the file register range to be cleared.
- Clearing with engineering tool: clear them using engineering tool (GX Works3 Operating Manual)

18.10 Refresh Data Register (RD)

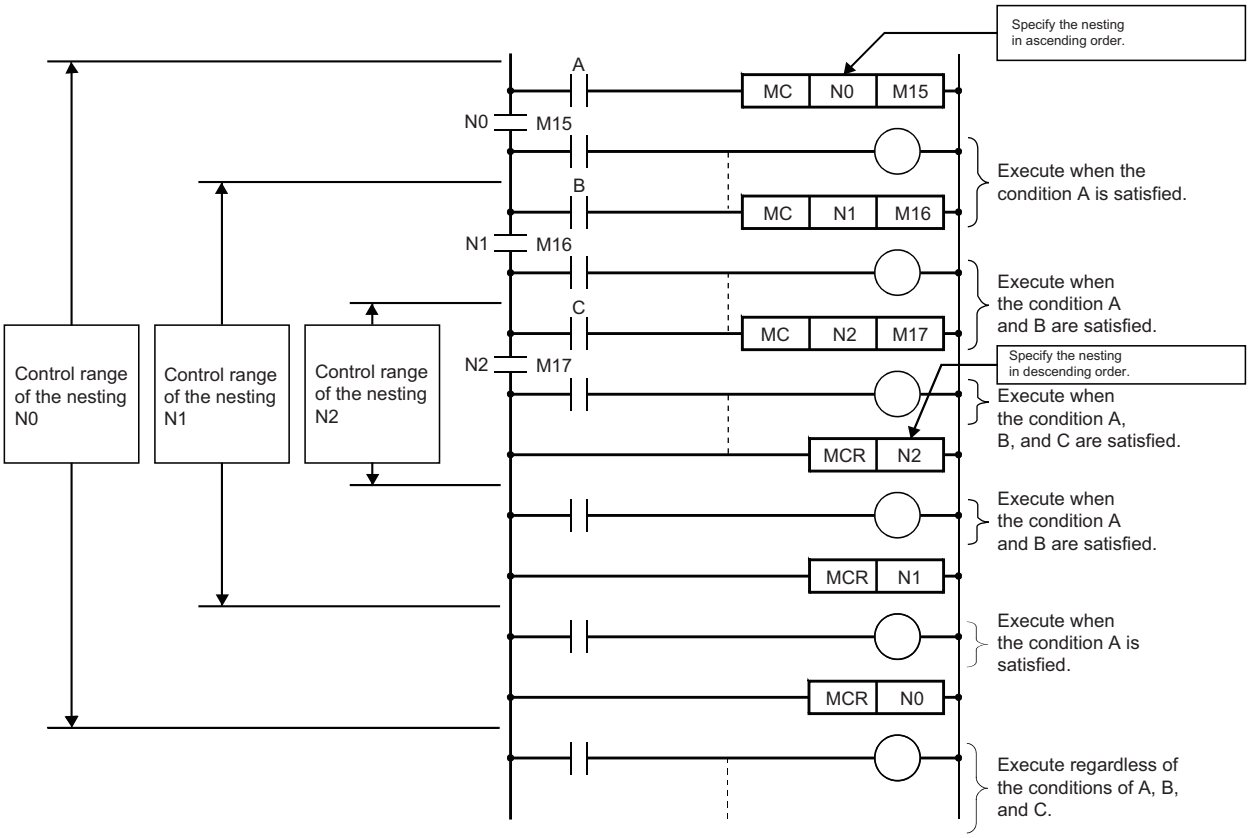


This device is provided for using as a refreshing target of buffer memory on the various devices, such as an intelligent function module. Refresh Data Register (RD) is assigned into the refresh memory area. (☞ Page 322 Refresh memory)

Refresh memory setting

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Memory/Device Setting] ⇨ [Refresh Memory Setting]

Window



Displayed items

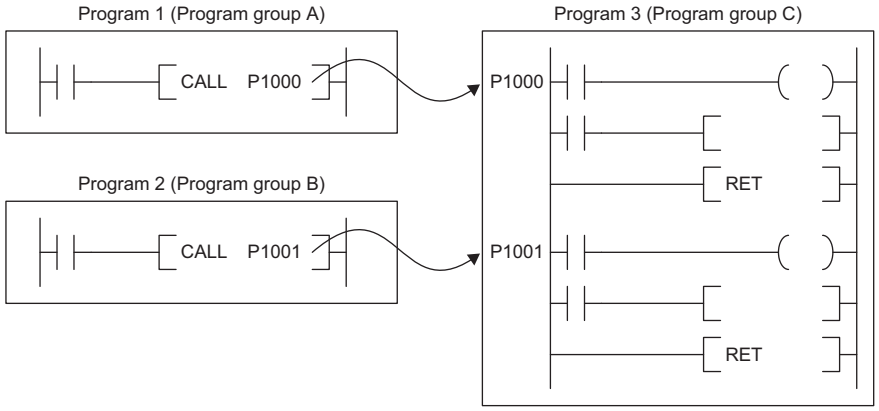
Item	Description	Setting range	Default
Total Points	Check the total number of points for the refresh data register and the assigned area.	—	4096K points
Refresh Data Register (RD) Area	Set the number of points of refresh data register.	0 to 4096K points (in one-point increments)*1	1024K points
Network Label/Module Label Assignment Area	Set the number of points in the network label/module label assignment area.	0 to 4096K points (in one-point increments)*1	3072K points

*1 Set it so that the total of the refresh data register (RD) area and network label/module label assignment area is 4096K points or less.

18.11 Nesting (N)

This device is used in the master control instructions (the MC/MCR instruction)*1 and enables the programming of operation conditions in a nesting structure. Specify this device from outside the nesting structure starting with the lowest number (in ascending order from N0 to N14).

*1 This instruction creates an effective ladder-switching program using opening/closing the common rail of the ladders.



18.12 Pointer (P)

This device is used in the jump instructions (the CJ/SCJ/JMP instruction) and/or subroutine program call instructions (such as the CALL instruction). There are two types of pointer: the global pointer and the local pointer. Use the pointer when:

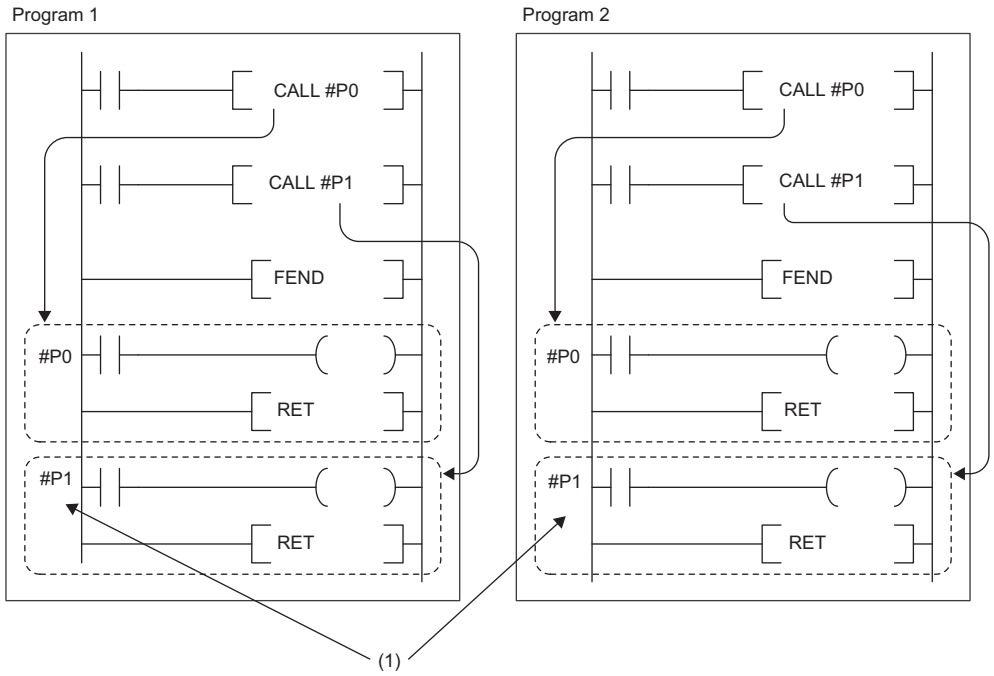
- Specifying the jump destination and label of the jump instructions (the CJ/SCJ/JMP instruction).
- Specifying the call destination and label (the head of subroutine program) of the subroutine call instructions (such as the CALL instruction).

Global pointer

This is the pointer which enables calling by the subroutine call instruction from all the program being executed.

Effective use of number of points

The number of points for global pointers can be obtained with the following formula: "number of points set by the parameters" - "the total number of points of the local pointers being used for each program".

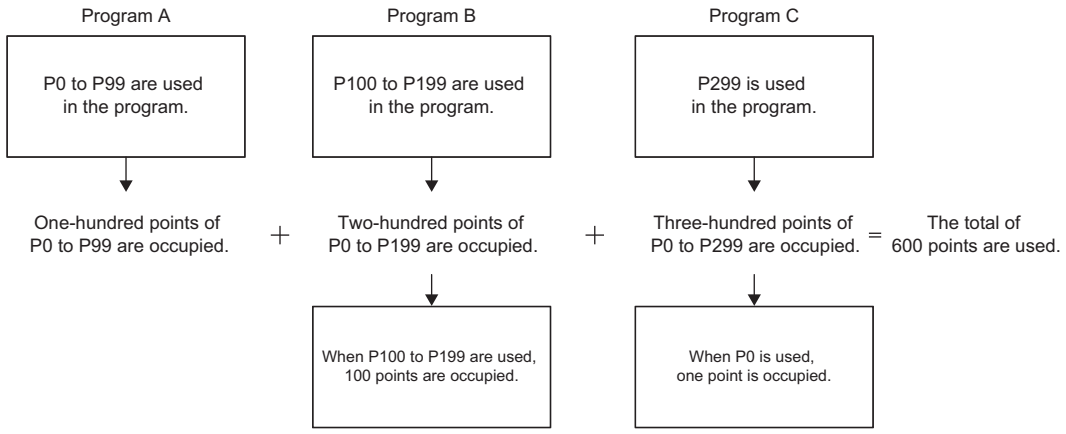


Precautions

This section describes the precautions when the global pointer is used.

- The global pointer with the same pointer number cannot be set as a label in multiple points.

Local pointer

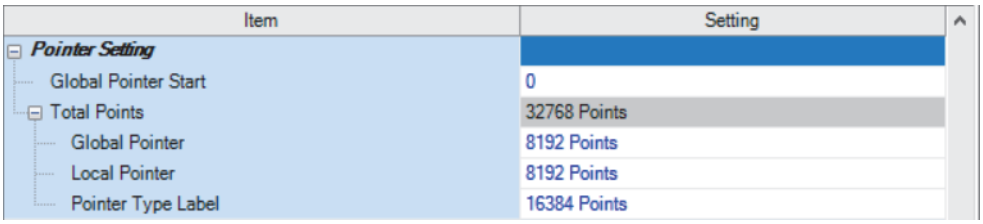


This is the pointer to be independently used in each program where the same pointer number can be used. This pointer is specified in the following format: # (pointer number) (Example: #P0) (☞ Page 394 Specification method for the local devices).

(1) The local pointers with the same number can be used between different programs.

Effective use of number of points

Local pointer number of points are shared among all the programs. The range of the local pointer number of points used by each program is from P0 to the maximum value of the local pointer being used in that program. For example, even when a program actually uses only P99, 100 points (P0 to P99) are considered to be used. When local pointers are used in multiple programs, an effective way is to use them in ascending order, starting from P0, in each program group.



Pointer setting

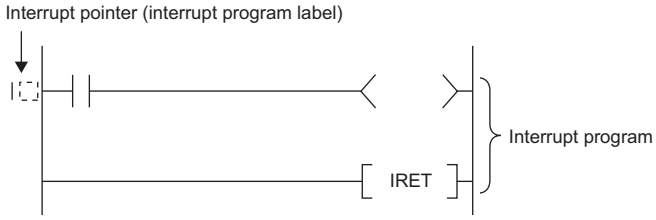
The following menu item is to set pointers.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Memory/Device Setting] ⇨ [Pointer Setting]

Window

Displayed items

Item	Description	Setting range		Default	
		MXR300-16 MXR300-32 MXR300-64	MXR500-128 MXR500-256	MXR300-16 MXR300-32 MXR300-64	MXR500-128 MXR500-256
Global Pointer Start	Set the start number of the global pointer.	0 or more*1		0	
Total Points	Check the total number of points for the pointer.	0 to 16384 points (in one-point increments)	0 to 32768 points (in one-point increments)	16384 points	32768 points
Global Pointer	Set the number of points of the global pointer.	0 to 16384 points (in one-point increments)	0 to 32768 points (in one-point increments)	4096 points	8192 points
Local Pointer	Set the number of points of the local pointer.			4096 points	8192 points
Pointer Type Label	Set the number of points for the pointer type label assignment area.			8192 points	16384 points



*1 Up to the number of "the total number of points - the number of points for global pointers".

Point

Specify a pointer number which is equal to or lower than "(end number of the pointer range specified in the parameter) - (number of points of the global pointers)".

18.13 Interrupt Pointer (I)

This device is used as a label located at the head of the interrupt program. This pointer can be used in all the programs being executed.

Point

Setting the execution type of program to the event execution type eliminates the need to write (I☐) the interrupt pointer. (☞ Page 255 Interruption Occurrence)

Interrupt factors of the interrupt pointer numbers

The interrupt factors of the interrupt pointer numbers are indicated.

Interrupt factor	Interrupt pointer number	Description
Interrupt from module	I0 to I15	This is a pointer used for modules which have the interrupt function.
Interrupt by the internal timer	I28 to I31	This interrupt pointer is used in fixed scan interrupts by the internal timer.
High-speed internal timer interrupt 2	I48	This interrupt pointer is used in fixed scan interrupts by the internal timer and can be specified in a shorter interval than interrupt pointer numbers I28 to I31.
High-speed internal timer interrupt 1	I49	
Interrupt from module	I50 to I1023	This is a pointer used for modules which have the interrupt function.

Priority for the interrupt pointer numbers and interrupt factors

The priority for the interrupt pointer numbers and interrupt factors are indicated.

Interrupt pointer number	Interrupt factor		Default priority
I0	Interrupt from module	1st point	32
I1		2nd point	
I2		3rd point	
I3		4th point	
I4		5th point	
I5		6th point	
I6		7th point	
I7		8th point	
I8		9th point	
I9		10th point	
I10		11th point	
I11		12th point	
I12		13th point	
I13		14th point	
I14		15th point	
I15		16th point	
I28	Interrupt by the internal timer		28
I29			
I30			
I31			
I48	High-speed internal timer interrupt 2		4
I49	High-speed internal timer interrupt 1		3
I50 to I1023	Interrupt from module		32

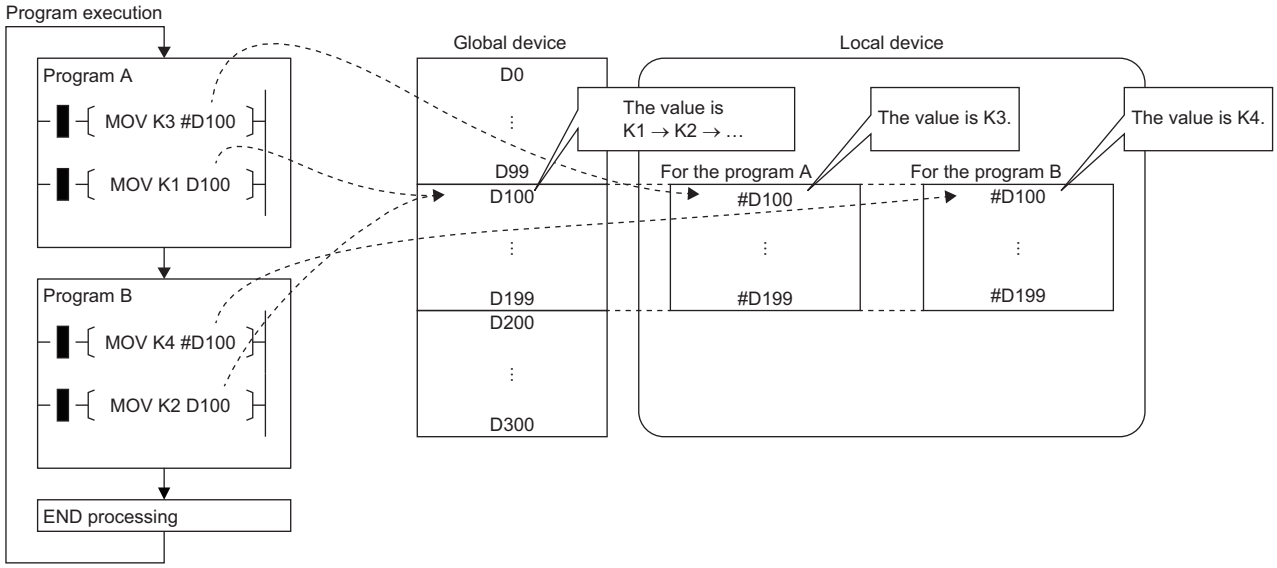
Point

- The interrupt priority is the order which is executed at the time of the multiple interrupt. (☞ Page 274 Interrupt priority)
- The interrupt priority order is the order which is executed when the interrupt factor with the same interrupt priority is generated. (☞ Page 276 Interrupt priority order)

18.14 Network No. Specification Device (J)

This device is used when specifying a network number with the Link dedicated instruction. (MELSEC MX Controller MX-R Model Programming Manual)

18.15 I/O No. Specification Device (U)



This device is used when specifying an I/O number with the intelligent function module dedicated instruction. (MELSEC MX Controller MX-R Model Programming Manual)

18.16 Global Device

This device can be shared by all the programs.

18.17 Local Device

This device can be used independently in each program. When creating multiple programs, programming can be completed without being aware of devices used in other programs.

Point

The local device area must be reserved independently from the global device area. Therefore a local device and global device with the same device number can exist.

Devices available as local device

The following devices are available as local devices.

- Internal relay (M)
- Edge relay (V)
- Timer (T, LT, ST, LST)
- Counter (C, LC)
- Data register (D)
- Index register (Z, LZ)
- Pointer (P)

Local device area

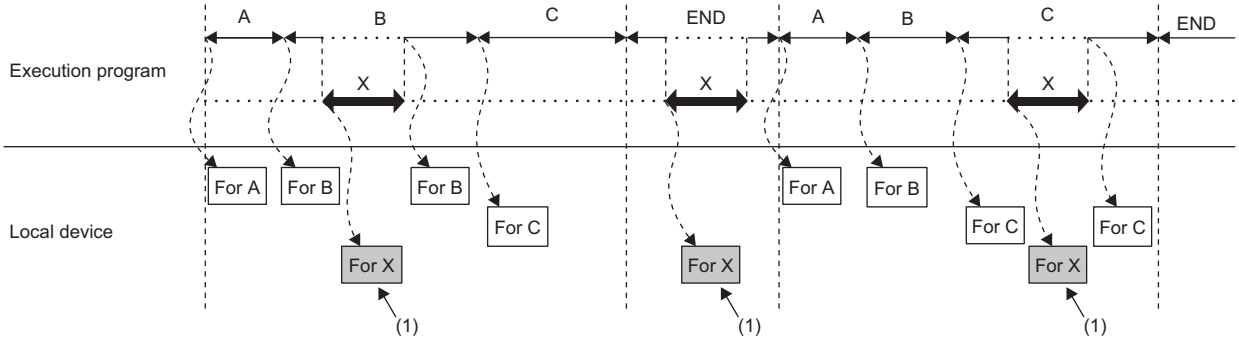
The controller reserves the local device area on the device/label memory based on the number of points setting of the local device at the following timing.

- When the controller is powered off and on or is reset.
- When the operating status of the controller is switched from STOP to RUN

When local device is used in subroutine program

Local devices to be used vary depending on whether SM776 (Local device setting at CALL) is turned on or off. Local index register to be used is also determined according to the SM776 setting.

SM776	Local device to be used
Off	Uses local devices of the program file from which subroutine program is called.
On	Uses local devices of the program file into which the subroutine program is stored.



Restriction

- In terms of on/off setting for SM776, the value (on or off) used when the subroutine call occurs is considered to be effective. Therefore when on/off setting for SM776 is switched in the subroutine program, the modified value (on or off) is not effective until the next subroutine call occurs.
- On/off setting for SM776 cannot be specified for each program file because it is enabled for each controller.

When local device is used in interrupt and other programs

The following shows cases when using a local device for an interrupt program, a fixed scan execution type program, or an event execution type program triggered by occurrence of an interrupt.

Program name	Execution type	Local device use/not use
A	Scan	Use
B	Scan	Use
C	Scan	Use
X	Fixed scan	Use

(1) Uses the program X local device.

Restriction

When the local device monitor is executed, the monitor switches to the applicable local device.

Clearing local device

Local device can be cleared to 0 by the following operations:

- When the controller is powered off and on or is reset.
- When the operating status of the controller is switched from STOP to RUN*1
- When the operating status of the controller is switched from PAUSE to RUN*1

*1 Only when "Device/Label Initial Value Reflection Setting at STOP to RUN" is set to "Enable" by selecting the following: Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [File Setting] ⇨ [Device/Label Initial Value Reflection Setting]
☞ Page 427 Initial value setting

Setting method for the local devices

Set the range where each device will be used as a local device and also set whether or not it should be used.

■Range setting

The range setting for local devices is common to all the programs. Therefore, the range for local devices cannot be set for each program.

Operating procedure

"Device/Label Memory Area Detailed Setting" window

1. Click "Detailed Setting" on the "Device Setting" window.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Memory/Device Setting] ⇨ [Device/Label Memory Area Setting] ⇨ [Device/Label Memory Area Detailed Setting] ⇨ [Device Setting] ⇨ <Detailed Setting>

2. Set the range where each device will be used as a local device.

"Device Setting" window

Item	Symbol	Device	
		Points	Range
Input	*X*	12K	0 to 2FFF
Output	Y	12K	0 to 2FFF
Internal Relay	M	64K	0 to 65535
Link Relay	B	32K	0 to 7FFF
Link Special Relay	SB	2K	0 to 7FF
Annunciator	F	2K	0 to 2047
Edge Relay	V	2K	0 to 2047
Step Relay	S	0	
Timer	T	1K	0 to 1023
Long Timer	LT	4K	0 to 4095
Retentive Timer	ST	0	
Long Retentive Time	LST	0	
Counter	C	512	0 to 511
Long Counter	LC	512	0 to 511
Data Register	D	64K	0 to 65535
Link Register	W	32K	0 to 7FFF
Link Special Registe	SW	2K	0 to 7FF
Latch Relay	L	8K	0 to 8191
Total Device			125.2K Word
Total Word Device			116.5K Word
Total Bit Device			138.0K Bit

Point

Configure the setting range of the local device within the range which has been set for the number of device points. The number of local devices used is calculated by the following calculation formula. Set the number of local devices used so that the number is equal to or less than the capacity of the local device area.

Total number of local devices used = ((A ÷ 16) + B + (C × 2) + (D × 4) + ((E × 2) ÷ 16)) × F

- A: Number of points of the local devices M and V
- B: Number of points of the local devices D, T (current value), ST (current value), and C (current value)
- C: Number of points of the local device LC (current value)
- D: Number of points of the local devices LT and LST
- E: Number of points of the local devices T (contact/coil), ST (contact/coil), C (contact/coil), and LC (contact/coil)
- F: Number of programs using the local device

■Setting unit

The increment of setting of a local device is the same as that of a global device. (☞ Page 348 Range of use of device points)

Setting whether or not it should be used

Whether or not to use local devices cannot be set for each program.

Specification method for the local devices

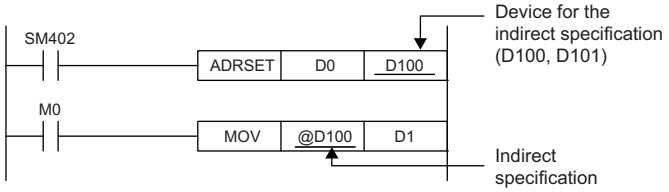
To specify the local device in the program, add "#".

Ex.

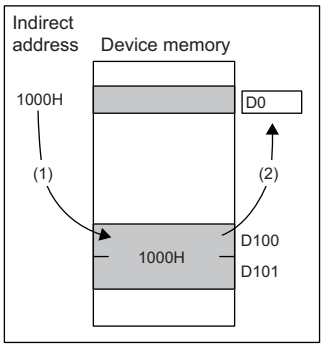
For example, #D100, K4#M0, and @#D0 can be used.

Point

- Local device is listed with a preceding # symbol in the program. This symbol is helpful to differentiate local devices from global devices.
- The local index register performs index modification on other devices. Therefore, unlike other local device specifications, the device name is not preceded by "#".



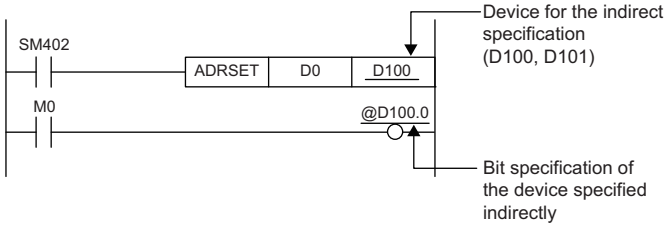
Precautions



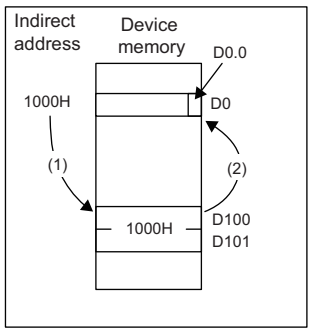
This section describes the precautions when using local devices.

- Accessing the range including both global and local devices by the index modification is not allowed.
- Local devices are not latched.

18.18 Device Indirect Specification



Specify the device using the indirect address of device. Store the indirect address of device to be specified into the device for indirect specification, and write as "@ + Device for indirect specification".



(1) The indirect address of D0 is read into D100, D101.
(2) The indirect address is used to indirectly specify D0.

Besides, specifying a bit of a word device allows the indirect specification for the instruction that specifies bits.

(1) The indirect address of D0 is read into D100, D101.
(2) The indirect address is used to output at the 0th bit of D0 which was indirectly specified using the indirect address.

The indirect specification can be used in the device/label memory or refresh memory.

Indirect address of device

To specify, use the 32-bit data, and to hold the value, use the device of two words. The indirect address of the device can be obtained with the ADRSET instruction. The ADRSET instruction specifies the indirect address of the device using instructions that handle 32-bit data. For the ADRSET instruction, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

Point

When the block or the file of the file register is switched through the RSET instruction, the indirect address refers to the one of the block or the file before they are switched. To allow the indirect address in the device for indirect specification to specify the block or file after the file register is switched, specify the ADRSET instruction to obtain the indirect address again after block or file are switched.

Devices that can allow indirect specification

This section lists devices that can allow indirect specification.

Type	Device*3
Devices that can allow indirect specification where @ is added*1	T, ST, C, D, W, SW, FD, SD, Un\G, Jn\W, Jn\SW, U3En\G, R, ZR, RD
Devices that can acquire the indirect address through the ADRSET instruction*2	X, Y, M, L, B, F, SB, T, ST, LT, LST, C, LC, D, W, SW, FX, FY, FD, SM, SD, R, ZR, RD

*1 Also can be used for the local device. (e.g.: @#D0)
*2 The indirect address of device can be obtained for the local device as well. (e.g.: ADRSET #D0 D100)
*3 Devices that cannot be used as operands of instructions cannot be used even when they are indirectly specified.

18.19 Constants

This section describes constants.

Decimal constant (K)

Use this type of constants when specifying decimal data in a program. Specify the decimal constant using K☐ character (e.g. K1234). The specification range depends on the argument data type of the instruction using the decimal constant as shown in the following table:

Argument data type of the instruction		Specification range for decimal constant
Data size	Data type name	
16 bit	Word (signed)	K-32768 to K32767
	Word (unsigned)/bit string (16 bit)	K0 to K65535
	16-bit data	K-32768 to K65535
32 bit	Double word (signed)	K-2147483648 to K2147483647
	Double word (unsigned)/bit string (32 bit)	K0 to K4294967295
	32-bit data	K-2147483648 to K4294967295

Hexadecimal constant (H)

Use this type of constants when specifying hexadecimal data in a program. Specify the hexadecimal constant using H☐ character (e.g. H1234). To specify data in BCD, specify each digit of hexadecimal value with numerical characters 0 to 9. The specification range depends on the argument data type of the instruction using the hexadecimal constant. The range is H0 to HFFFF for 16-bit data size, and H0 to HFFFFFFFF for 32-bit data size.

Real constant (E)

Use this type of constants when specifying a real number in a program. There are two types of real numbers: single-precision real number and double-precision real number. Specify it using E☐character. (e.g. E1.234).

Setting range for real numbers

The setting ranges are different between the single-precision real number and double-precision real number.

■Specification range for single-precision real numbers

The following is the specification range for single-precision real numbers.

$-2^{128} < \text{device} \leq -2^{-126}$, 0, $2^{-126} \leq \text{device} < 2^{128}$

(E-3.40282347+38 to E-1.17549435-38, 0, E1.17549435-38 to E3.40282347+38)

■Specification range for double-precision real number

The following is the specification range for single-precision real numbers.

$-2^{1024} < \text{device} \leq -2^{-1022}$, 0, $2^{-1022} \leq \text{device} < 2^{1024}$

(E-1.7976931348623157+308 to E-2.2250738585072014-308, 0, E2.2250738585072014-308 to E1.7976931348623157+308)

Point

For the number of significant digits and input range of real number data input by the engineering tool, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

Processing when operation is in progress

This section describes the processing when operation is in progress.

■When overflow and/or underflow occurs:

If an overflow and/or underflow occurs when the operation is in progress, the following process is performed:

- When overflow occurs: An error is returned.
- When underflow occurs: 0 is returned (no error occurs).

■When a special value is input:

When a special value*1 is used for the input data operation, an error is returned. Note that when "-0" is generated during the operation is in progress, it is handled as "+0" and therefore "-0" is not returned as an operation result.

*1 The special values include -0, denormalized number, nonnumeric number, and ±∞.

Character string constant

The character string can be specified by enclosing it with single quotation marks (' ') or double quotation marks (" "). (Example: "ABCDE") Note that the NULL character (00H) becomes the termination character.

Point

For details on character string data, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

Notation of constants

This section describes the notation of constants.

Type		Notation	Example	Applicable data type
Boolean value		Set "FALSE" or "TRUE".	TRUE, FALSE	Bit
		Add "K" or "H" before "0" or "1".	K0, K1, H0, H1	
Integral	Binary	Add "2#" before a binary number.	2#0010, 2#01101010, 2#1111_1111	• Word [unsigned]/bit string [16 bits] • Double word [unsigned]/bit string [32 bits] • Word [signed] • Double word [signed]
	Octal	Add "8#" before an octal number.	8#0, 8#337, 8#1_1	
	Decimal	Directly enter a signed or unsigned decimal number.	123, +123, -123, 12_3	
		Add "K" before a signed or unsigned decimal number.	K123, K-123	
	Hexadecimal	Add "16#" before a hexadecimal number.	16#FF, 16#1_1	
		Add "H" before a hexadecimal number.	HFF, HEAD	
Real number	Decimal notation	Directly enter a signed or unsigned real decimal number with a decimal point.	2.34, +2.34, -2.34, 3.14_15	• Single-precision real number • Double-precision real number
		Add "E" before a signed or unsigned real decimal number with a decimal point.	E2.34, E-2.34	
	Exponential notation	Add "E" and a signed or unsigned exponent (decimal) at the end of the real number.	1.0E6, 1.0E-6	
		Add a signed exponent (decimal) at the end of the real number with "E".	E1.001+5, E1.001-6	
String	String	Enclose a string in single quotation marks (' ').	'ABC'	String
	String [Unicode]	Enclose a string in double quotation marks (" ").	"ABC"	String [Unicode]
Time		Add "T#" or "TIME#" at the beginning. (☞ Page 398 Notation of time)	T#1h, T#1d2h3m4s5ms, TIME#1h	Time

Point

In the notation of binary, octal, decimal, hexadecimal, and real numbers, the numbers can be separated using an underscore (_) to make programs easy to see. For example, the double word [unsigned] in the notation of binary is as follows.

2#1100_1100_1100_1100

The separations by underscores (_) are ignored in program processing.

Notation of time

In the notation of time, add "T#" or "TIME#" at the beginning of the value specified in units of time; d (day), h (hour), m (minute), s (second), and ms (millisecond). The following table lists the effective range for each unit of time.

Item	Effective range
d (day)	0 to 24
h (hour)	0 to 23
m (minute)	0 to 59
s (second)	0 to 59
ms (millisecond)	0 to 999

- Each unit of time can be omitted sequentially from the beginning to the end or in reverse order.
  T#31m23s, T#31m0s648ms
- A sign can be added only before the first unit of time.
  T#-31m23s
- An unsigned real decimal number with a decimal point can be used for the last unit of time. The values after the decimal point of ms (millisecond) are rounded down.
  T#-24d20h31m23s648.123ms (The time is treated as T#-24d20h31m23s648ms.)
  T#1.2345ms (The time is treated as T#1ms.)
- Only for the first unit of time other than d, the following values within the effective range can be input.
  h: 0 to 596
  m: 0 to 35791
  s: 0 to 2147483
  ms: 0 to 2147483647

Special character (escape sequence)

"$" is used as an escape sequence in a string. The following characters can be input as escape sequences with "$".

Symbol used in a string or printer code	Escape sequence
$	$$
'	$'
"	$"
Line feed	$L or $l
Line break	$N or $n
Page feed	$P or $p
Return	$R or $r
Tab	$T or $t
Two hexadecimal digits and characters that correspond to the ASCII code	Two hexadecimal digits following $

If the two hexadecimal digits following "$" do not correspond to the ASCII code, a conversion error occurs.

19 LABELS

A label is a variable consisting of a specified string used in I/O data or internal processing.
Programs can be created without considering the size of devices and buffer memory by using labels. For this reason, a program using labels can be reused easily even in a system having a different module configuration.
When labels are used, there are some precautions on programming and functions used. For details, refer to the following.
☞ Page 415 Precautions

Point

There are two types of labels described in this manual.
- Global labels
- Local labels

There are other types of labels available in addition to the global labels and local labels.
[System labels]
A system label is a label that provides the same data in all projects compatible with iQ Works. It can be referenced from the GOT and the controller and motion controllers on other stations, and used for monitoring and accessing data.
For details, refer to the following.
📖Let's start iQ Works Version 2
[Network labels]
Once a network label is created, the label access can be executed to other modules on the network, which are not on the same base unit.
The network label is created for remote stations and is registered as a global label.
For the network label creation procedure, refer to the following.
☞ Page 108 Network labels
For the list of labels used by the motion control FB, refer to the following.
📖MELSEC MX Controller MX-R Model Programming Manual

19.1 Global Labels

A global label is a label that provides the same data within a single project. It can be used in all programs in the project.
A global label can be used in program blocks and FB.
The settings of a global label include a label name, class, and data type.
By opening global labels, they can be referenced from GOTs and the controllers on other stations, and can be used for monitoring and accessing data.

Device assignment

Devices can be assigned to global labels.

Item	Description
Label to which no device is assigned	• Programming without being aware of devices is possible. • Defined labels are allocated to the label area or latch label area in the device/label memory.
Label to which a device is assigned	• When a device is to be programmed as a label against a device that is being used for input or output, the device can be assigned directly. • Defined labels are allocated to the device area in the device/label memory.

Module label

A module label is a label defined uniquely by each module. A module label is automatically generated by the engineering tool from the module used, and can be used as a global label.
The I/O signals, buffer memory, SM, SD, SB, and SW of the controller can be accessed using a module label.

Structure of the module label

The module label name is defined with the following structure.

- Instance name.Label name
- Instance name.Label name_D

(_D indicates that the module label is for direct access.)

■Instance name

The following table lists the instance names.

Item	Instance name
CPU function part	MX_SQ
CC-Link IE TSN function part	MX_TSN
Motion function part	MX_MT

19.2 Local Labels

A local label is a label that can be used only in the declared POU. Local labels outside the declared POU cannot be used.
The settings of a local label include a label name, class, and data type.

19.3 Classes

The label class indicates from which POU and how a label can be used.
Different classes can be selected depending on the type of POU.

Global label

The following table lists the global label classes and applicable POUs.

Class	Description	Applicable POU		
		Program block	Function block (FB)	Function (FUN)
VAR_GLOBAL	A common label that can be used in both program blocks and FB	○	○	×
VAR_GLOBAL_CONSTANT	A common constant that can be used in both program blocks and FB	○	○	×
VAR_GLOBAL_RETAIN	A latch type label that can be used in both program blocks and FB	○	○	×

Local label

The following table lists the local label classes and applicable POUs.

Class	Description	Applicable POU		
		Program block	Function block (FB)	Function (FUN)
VAR	A label that can be used within the range of a declared POU. This label cannot be used in other POUs.	○	○	○
VAR_CONSTANT	A constant that can be used within the range of a declared POU. This label cannot be used in other POUs.	○	○	○
VAR_RETAIN	A latch type label that can be used within the range of a declared POU. This label cannot be used in other POUs.	○	○	×
VAR_INPUT	A label that inputs a value into a function or FB This label receives a value, and the received value cannot be changed in a POU.	×	○	○
VAR_OUTPUT	A label that outputs a value from a function or FB	×	○	○
VAR_OUTPUT_RETAIN	A latch type label that outputs a value from an FB	×	○	×
VAR_IN_OUT	A local label that receives a value and outputs the value from a POU. The value can be changed in a POU.	×	○	×
VAR_PUBLIC	A label that can be accessed as the public variable from other POUs	×	○	×
VAR_PUBLIC_RETAIN	A latch type label that can be accessed as the public variable from other POUs	×	○	×

19.4 Data Types

The data types of a label are classified according to the bit length, processing method, and value range.

There are two data types.

- Primitive data type
- Generic data type (ANY type)

Primitive data type

The following table lists the data types included in the primitive data type.

Data type		Description	Value range	Bit length
Bit	BOOL	Represents the alternative status, such as on or off.	0 (FALSE), 1 (TRUE)	1 bit
Word [unsigned]/bit string [16 bits]	WORD	16-bit array	0 to 65535	16 bits
Double word [unsigned]/ bit string [32 bits]	DWORD	32-bit array	0 to 4294967295	32 bits
Word [signed]	INT	Positive and negative integer values	-32768 to 32767	16 bits
Double word [signed]	DINT	Positive and negative double-precision integer values	-2147483648 to 2147483647	32 bits
Single-precision real number*1	REAL	Numerical values of decimal places (single-precision real number values)	-2^{128} to -2^{-126}, 0, 2^{-126} to 2^{128} E-3.402823+38 to E-1.175495-38, 0, E1.175495-38 to E3.402823+38	32 bits
Double-precision real number*1	LREAL	Numerical values of decimal places (double-precision real number values)	-2^{1024} to -2^{-1022}, 0, 2^{-1022} to 2^{1024} E-1.79769313486231+308 to E-2.22507385850721-308, 0, E2.22507385850721-308 to E1.79769313486231+308	64 bits
Time*2	TIME	Numerical values as day, hour, minute, second, and millisecond (☞ Page 398 Notation of time)	T#-24d20h31m23s648ms to T#24d20h31m23s647ms	32 bits
String	STRING	Characters represented by ASCII code or Shift JIS code	255 one-byte characters maximum	Variable
String [Unicode]	WSTRING	Characters represented by Unicode	255 characters maximum	Variable
Timer	TIMER	Structure corresponding to the device, timer (T)	☞ Page 403 Timer and counter data types	
Retentive timer	RETENTIVETIMER	Structure corresponding to the device, retentive timer (ST)		
Long timer	LTIMER	Structure corresponding to the device, long timer (LT)		
Long retentive timer	LRETENTIVETIMER	Structure corresponding to the device, timer (LST)		
Counter	COUNTER	Structure corresponding to the device, counter (C)		
Long counter	LCOUNTER	Structure corresponding to the device, counter (LC)		
Pointer	POINTER	Type corresponding to the device, pointer (P) (☞ Page 385 Pointer (P))		

*1 For the number of significant digits and input range of real number data input by the engineering tool, refer to the following.
MELSEC MX Controller MX-R Model Programming Manual

*2 The time type is used in a time data type function of standard functions. For standard functions, refer to the following.
MELSEC MX Controller MX-R Model Programming Manual

Point

- The bit data in the word type label can be used by specifying a bit number.
- The bit type array label can be used as 16-bit or 32-bit data by specifying the number of digits.

For the bit specification and digit specification methods, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

■Timer and counter data types

The data types of the timer, counter, long counter, retentive timer, long retentive timer, and long timer are the structures having a contact, coil, and current value.

Data type		Member name	Member data type	Description	Value range
Timer	TIMER	S	Bit	Indicates a contact. The operation is the same as the contact (TS) of a timer device.	0 (FALSE), 1 (TRUE)
		C	Bit	Indicates a coil. The operation is the same as the coil (TC) of a timer device.	0 (FALSE), 1 (TRUE)
		N	Word [unsigned]/bit string [16 bits]	Indicates the current value. The operation is the same as the current value (TN) of a timer device.	0 to 65535*1
Retentive timer	RETENTIVETIMER	S	Bit	Indicates a contact. The operation is the same as the contact (STS) of a retentive timer device.	0 (FALSE), 1 (TRUE)
		C	Bit	Indicates a coil. The operation is the same as the coil (STC) of a retentive timer device.	0 (FALSE), 1 (TRUE)
		N	Word [unsigned]/bit string [16 bits]	Indicates the current value. The operation is the same as the current value (STN) of a retentive timer device.	0 to 65535*1
Long timer	LTIMER	S	Bit	Indicates a contact. The operation is the same as the contact (LTS) of a long timer device.	0 (FALSE), 1 (TRUE)
		C	Bit	Indicates a coil. The operation is the same as the coil (LTC) of a long timer device.	0 (FALSE), 1 (TRUE)
		N	Double word [unsigned]/bit string [32 bits]	Indicates the current value. The operation is the same as the current value (LTN) of a long timer device.	0 to 4294967295*1
Long retentive timer	LRETENTIVETIMER	S	Bit	Indicates a contact. The operation is the same as the contact (LSTS) of a long retentive timer device.	0 (FALSE), 1 (TRUE)
		C	Bit	Indicates a coil. The operation is the same as the coil (LSTC) of a long retentive timer device.	0 (FALSE), 1 (TRUE)
		N	Double word [unsigned]/bit string [32 bits]	Indicates the current value. The operation is the same as the current value (LSTN) of a long retentive timer device.	0 to 4294967295*1
Counter	COUNTER	S	Bit	Indicates a contact. The operation is the same as the contact (CS) of a counter device.	0 (FALSE), 1 (TRUE)
		C	Bit	Indicates a coil. The operation is the same as the coil (CC) of a counter device.	0 (FALSE), 1 (TRUE)
		N	Word [unsigned]/bit string [16 bits]	Indicates the current value. The operation is the same as the current value (CN) of a counter device.	0 to 65535
Long counter	LCOUNTER	S	Bit	Indicates a contact. The operation is the same as the contact (LCS) of a long counter device.	0 (FALSE), 1 (TRUE)
		C	Bit	Indicates a coil. The operation is the same as the coil (LCC) of a long counter device.	0 (FALSE), 1 (TRUE)
		N	Double word [unsigned]/bit string [32 bits]	Indicates the current value. The operation is the same as the current value (LCN) of a long counter device.	0 to 4294967295

*1 The unit of the current value is set in CPU parameters ("Timer Limit Setting").

For details on the operation of each device, refer to the following.

☞ Page 346 DEVICES AND CONSTANTS

The specification method of each member is the same as that of the structure data type. (☞ Page 410 Structures)

Generic data type (ANY type)

The generic data type is the data type of the labels which summarize several primitive data types.

Generic data types are used when multiple data types are allowed for function and FB arguments and return values.

Labels defined in generic data types can be used in any sub-level data type.

For the types of generic data types and the primitive data types, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

Definable data types and initial values

The following tables list the definable data types and initial value setting possibilities for each label class.

■Global label

Class	Definable data type	Initial value setting possibility
VAR_GLOBAL	Primitive data type[*1]	Possible
	Timer type, retentive timer type, long timer type, long retentive timer type, counter type, long counter type	Not possible
	Pointer type	Not possible
	Structure type	Possible
	FB	Possible
	Array type	Possible
VAR_GLOBAL_CONSTANT	Primitive data type[*1]	Not possible
VAR_GLOBAL_RETAIN	Primitive data type[*1]	Possible
	Timer type, retentive timer type, long timer type, long retentive timer type, counter type, long counter type	Not possible
	Structure type	Possible
	Array type	Possible

■Local label (program block)

Class	Definable data type	Initial value setting possibility
VAR	Primitive data type[*1]	Possible
	Timer type, retentive timer type, long timer type, long retentive timer type, counter type, long counter type	Not possible
	Pointer type	Not possible
	Structure type	Possible
	FB	Possible
	Array type	Possible
VAR_CONSTANT	Primitive data type[*1]	Not possible
VAR_RETAIN	Primitive data type[*1]	Possible
	Timer type, retentive timer type, long timer type, long retentive timer type, counter type, long counter type	Not possible
	Structure type	Possible
	Array type	Possible

■Local label (function)

Class	Definable data type	Initial value setting possibility
VAR	Primitive data type[*2], pointer type, array type, structure type	Not possible
VAR_CONSTANT	Primitive data type[*1]	Not possible
VAR_INPUT	Primitive data type[*1], array type, structure type	Not possible
VAR_OUTPUT		Not possible
Return value		Not possible

■Local labels (FB)

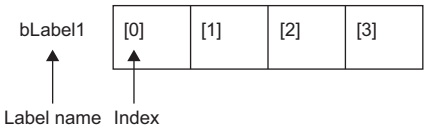
Class	Definable data type	Initial value setting possibility
VAR	Primitive data type*1	Possible
	Timer type, retentive timer type, long timer type, long retentive timer type, counter type, long counter type	Not possible
	Pointer type	Not possible
	Structure type	Possible
	FB	Possible
	Array type	Possible
VAR_CONSTANT	Primitive data type*1	Not possible
VAR_RETAIN	Primitive data type*1	Possible
	Timer type, retentive timer type, long timer type, long retentive timer type, counter type, long counter type	Not possible
	Structure type	Possible
	Array type	Possible
VAR_INPUT	Primitive data type*1	Possible
	Timer type, retentive timer type, long timer type, long retentive timer type, counter type, long counter type	Not possible
	Structure type	Possible
	Array type	Possible
VAR_OUTPUT	Primitive data type*1	Possible
	Timer type, retentive timer type, long timer type, long retentive timer type, counter type, long counter type	Not possible
	Structure type	Possible
	Array type	Possible
VAR_OUTPUT_RETAIN	Primitive data type*1	Possible
	Timer type, retentive timer type, long timer type, long retentive timer type, counter type, long counter type	Not possible
	Structure type	Possible
	Array type	Possible
VAR_IN_OUT	Primitive data type*1	Not possible
	Timer type, retentive timer type, long timer type, long retentive timer type, counter type, long counter type	Not possible
	Structure type	Possible
	Array type	Not possible
VAR_PUBLIC	Primitive data type*1	Possible
	Timer type, retentive timer type, long timer type, long retentive timer type, counter type, long counter type	Not possible
	Structure type	Possible
	Array type	Possible
VAR_PUBLIC_RETAIN	Primitive data type*1	Possible
	Timer type, retentive timer type, long timer type, long retentive timer type, counter type, long counter type	Not possible
	Structure type	Possible
	Array type	Possible

*1 The timer type, retentive timer type, long timer type, long retentive timer type, counter type, long counter type, and pointer type are excluded.

*2 The timer type, retentive timer type, long timer type, long retentive timer type, counter type, and long counter type are excluded.

Point

- The initial value of the global label where the device has been assigned follows that in the device.
- The initial value of the FB follows the local label setting within the FB.

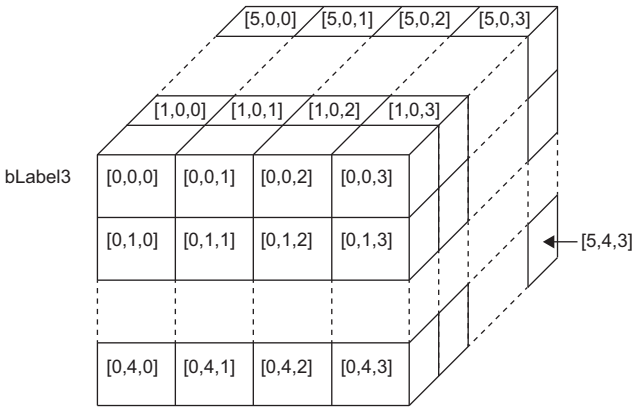


19.5 Arrays

An array represents a consecutive aggregation of the same data type labels as a single name.
Primitive data types, structures, and FB type can be defined as arrays.

Ex.

Array image and setting in engineering tool



- One-dimensional array (The number of elements is 4.)

- Two-dimensional array (The number of elements is 5 × 4.)

bLabel2				
	[0,0]	[0,1]	[0,2]	[0,3]
	[1,0]	[1,1]	[1,2]	[1,3]
	[4,0]	[4,1]	[4,2]	[4,3]

- Three-dimensional array (The number of elements is 6 × 5 × 4.)

- Settings in the engineering tool

	Label Name	Data Type		Class
1	bLabel1	Bit(0..3)	...	VAR
2	bLabel2	Bit(0..4,0..3)	...	VAR
3	bLabel3	Bit(0..5,0..4,0..3)	...	VAR

Defining arrays

■Array elements

When an array is defined, the number of elements, or the length of array, must be determined. For the range of the number of elements, refer to the following.

☞ Page 409 Range of the number of array elements

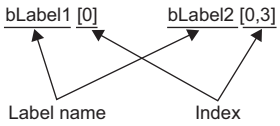
■Dimension number of multidimensional array

Up to three-dimensional array can be defined.

Only one-dimensional array can be defined for the maximum number of dimensions of FB type array.

■Definition format

The following table lists definition format.



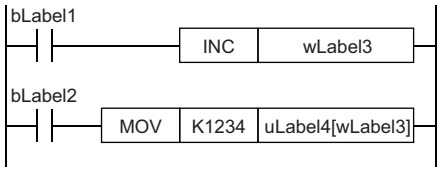
The range from the array start value to the array end value is the number of elements.

Number of array dimensions	Format	Remarks
One dimension	Array of primitive data type/structure name (array start value..array end value)	• For the primitive data type: ☞ Page 402 Primitive data type • For the structure name: ☞ Page 410 Structures
	[Definition example] Bit (0..15)	
Two dimensions	Array of primitive data type/structure name (array start value..array end value, array start value..array end value)	
	[Definition example] Bit (0..1, 0..15)	
Three dimensions	Array of primitive data type/structure name (array start value..array end value, array start value..array end value, array start value..array end value)	
	[Definition example] Bit (0..2, 0..1, 0..15)	

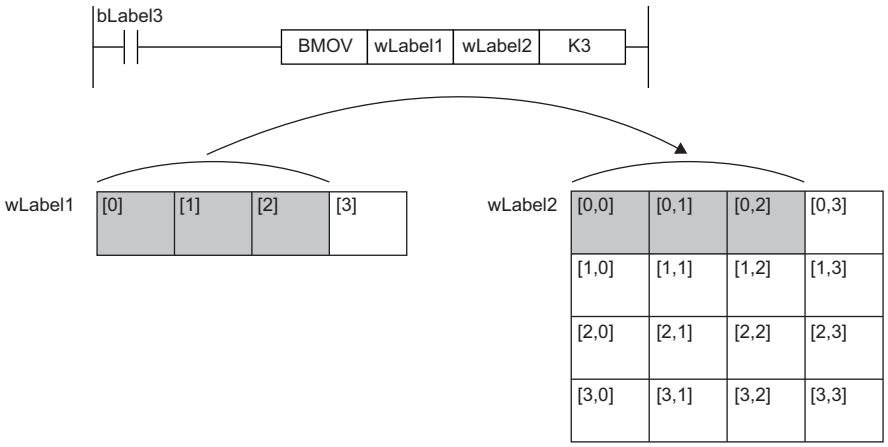
How to use arrays

To use an array, add an index enclosed by '[ ]' after each label name to identify individual labels.

An array with two or more dimensions should be expressed with indexes delimited by a comma (,) in '[ ]'.



The following table lists the types of indexes that can be specified for arrays.



Type	Specification example	Remarks
Constant	bLabel1[0]	An integer can be specified.
Device	bLabel1[D0]	A word device, double-word device, decimal constant, or hexadecimal constant can be specified. (ST, LST, G, and HG cannot be specified.)
Label	bLabel1[uLabel2]	The following data types can be specified. • Word [unsigned]/bit string [16 bits] • Double word [unsigned]/bit string [32 bits] • Word [signed] • Double word [signed]
Expression	bLabel1[5+4]	Expressions can be specified only in ST language.

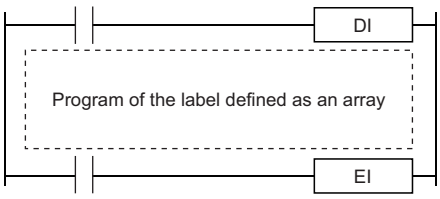
Point

- The data storage location becomes dynamic by specifying a label for the array index. This enables arrays to be used in a program that executes loop processing. The following is a program example that consecutively stores "1234" in the "uLabel4" array.

- The element number of the array can be omitted in ladder diagram. If the element number is omitted, it is regarded as the start number and converted. For example, when the defined label name is "boolAry" and the data type is "Bit (0..2, 0..2)", the operation of "boolAry[0,0]" is the same as that of "boolAry".
- When a multidimensional array is specified as setting data of instructions, standard functions, and standard FB that use arrays, the rightmost element is regarded as a one-dimensional array.

Range of the number of array elements

The maxim number of array elements varies depending on the data type.



Data type	Setting range
Bit Word [unsigned]/bit string [16 bits] Word [signed]	1 to 2147483648
Double word [unsigned]/bit string [32 bits] Double word [signed] Single-precision real number Time	1 to 1073741824
Timer Counter Retentive timer Long counter Long retentive timer Long timer	1 to 32768
Double-precision real number	1 to 536870912
String	1 to 67108864
String [Unicode]	1 to 33554432
Structure type FB type	1 to 32768

Precautions

■When an interrupt program is used

When a label or device is specified for the array index, the operation is performed with a combination of multiple instructions. For this reason, if an interrupt occurs during operation of the label defined as an array, data inconsistency may occur producing an unintended operation result.

To prevent data inconsistency, create a program using the DI/EI instructions that disables/enables interrupt programs as shown below.

For the DI/EI instructions, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

■Array elements

When accessing the element defined in an array, access it within the range of the number of elements.

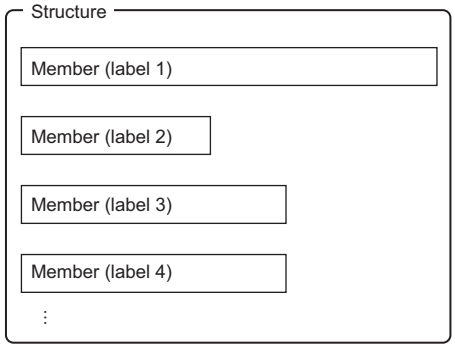
If a constant out of the range defined for the array index is specified, a compile error will occur.

If the array index is specified with data other than a constant, the following range check is performed to the element number when the label is accessed, and if the element number is outside of the range, Device, label, or buffer memory specification error (error code: 2820H) occurs.

- Check that the element number specified at the access to the start number and the number of elements defined in a label is within the range.
- Check that the element number of each dimension is within the range at the access to the multidimensional array label.

Note that the range for number of elements and padding are reserved in units of 16 bits for bit type arrays. Accessing a value outside the element number range of the bit type array does not result in an error if it is within the range including padding.

For details on the range check, refer to the following.

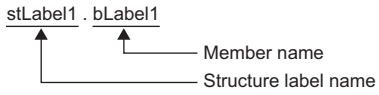


MELSEC MX Controller MX-R Model Programming Manual

19.6 Structures

A structure is a data type containing one or more labels and can be used in all POUs.
Members (labels) included in a structure can be defined even when their data types are different.

Creating structures

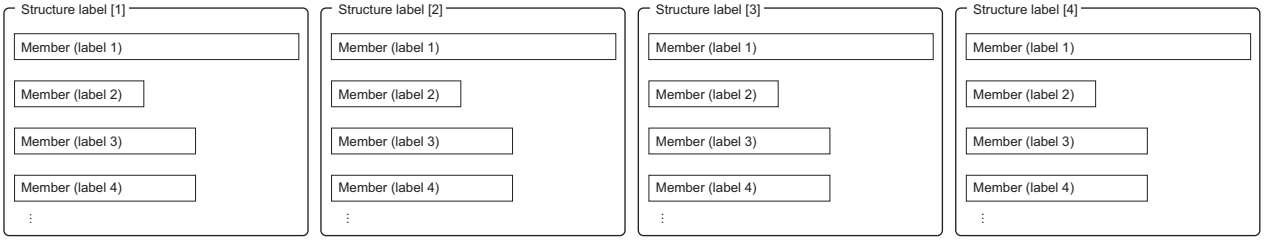


To create a structure, first define the structure, and then define members in the structure.

How to use structures

To use a structure, register a label using the defined structure as the data type.
To specify each member in a structure, add the member name after the structure label name with a period '.' as a delimiter in between.

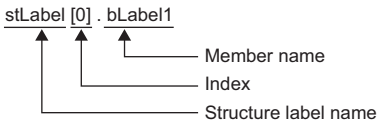
Ex.
Specifying a member in the structure



Point

The structure label is assigned in the order of label registration.
For details, refer to the following.
GX Works3 Operating Manual

Structure arrays



A structure can also be used as an array.

When a structure is declared as an array, add an index enclosed by '[ ]' after the structure label name.
A structure array can also be specified as an argument of a function or FB.

Ex.

Specifying an element of a structure declared as an array

Data types and initial values that can be specified

The following data types can be specified as structure members.

- Primitive data type*1
- Array
- Other structures

*1 The pointer type cannot be defined.

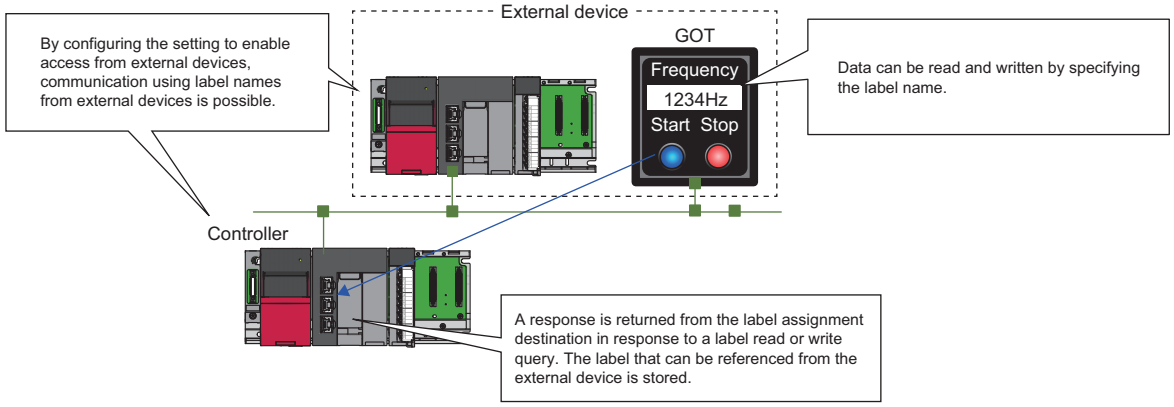
■Initial values

The following tables list the initial value setting possibilities.

Data type	Initial value setting possibility
Primitive data type	○
Timer type, retentive timer type, long timer type, long retentive timer type, counter type, long counter type	×
Structure type	×
Array type	○

Types of structures

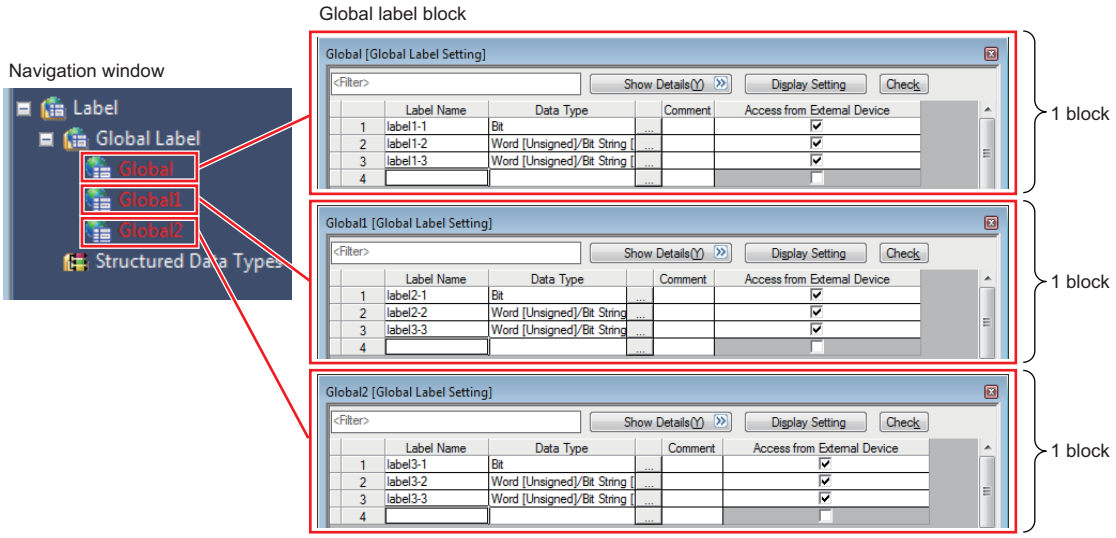
Each of the following labels is predefined as a structure.



Type	Reference
Module label	📖 Function Block Reference for the module used
Timer type	Page 402 Data Types
Retentive timer type	
Counter type	
Long timer type	
Long retentive timer type	
Long counter type	

Precautions

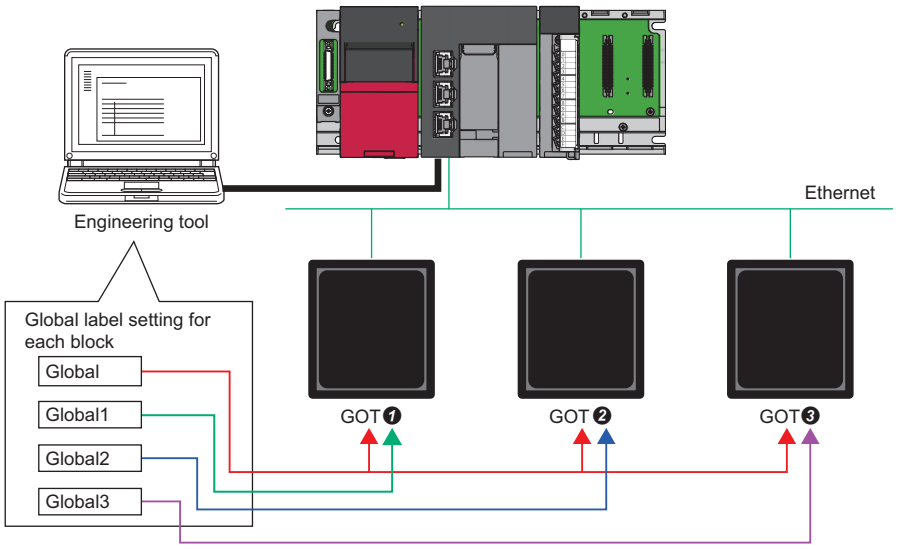
Do not access elements outside the range of the defined structure type label. When the label is specified with an instruction, a range check is performed. If a label outside the range is specified, an error occurs.
For details on the range check, refer to the following.
📖MELSEC MX Controller MX-R Model Programming Manual



19.7 Label Access Setting from External Device

This setting is used for reading/writing data by specifying label names from an external device that can communicate with the controller such as a monitoring device (including the GOT, SLMP-compatible device, and SCADA), or a personal computer.

Point

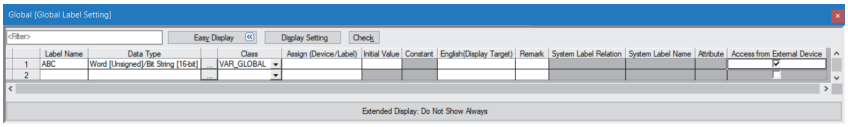


The controller controls global labels in the global label setting by block.
One global label setting is expressed as one block as below.

Set the global label setting for each label used with GOT in units of blocks.
When "Perform the label name resolution in global label block unit" is selected in the GT Designer3 setting, the label name resolution after online change is processed efficiently. However, during online change that involves addition of blocks, label names are resolved collectively, not in units of blocks.
For the GT Designer3 setting, refer to the following.
GT Designer3 (GOT2000) Screen Design Manual
The following shows an example of access to three GOT units.

- "Global": Global label setting that compiles labels accessed from multiple GOTs (GOT❶ to GOT❸)
- "Global1": Global label setting that compiles labels accessed from GOT❶
- "Global2": Global label setting that compiles labels accessed from GOT❷
- "Global3": Global label setting that compiles labels accessed from GOT❸

In this case, because global labels in each global label setting are accessed in units of blocks, the number of times of updating label communication data from GOT decreases.



Configuration procedure

This section describes the configuration procedure to enable access by specifying the global label from external devices.

Operating procedure

"Global Label Setting" window

1. Set the label in "Global Label Setting" and select the "Access from External Device" checkbox.
2. Check the capacity of the global label assignment information.

☞ Page 414 Maximum capacity of global label assignment information

3. Write parameters, global label settings, and global label assignment information files to the controller.

Global label assignment information

The global label assignment information consists of the label name and label system information, which are label assignment information of the global label with the "Access from External Device" checkbox selected. Label system information refers to label data type and assignment destination device information.

By writing global label assignment information to the controller, communication becomes possible with label names specified from external devices and auto-tracking becomes available when label assignments are changed. In the controller, the written global label assignment information is stored in the area (label assignment information management area) dedicated for this function and label communications are performed.

The label assignment information management area is used by the system even if global label assignment information is not written.

Maximum capacity of global label assignment information

The capacity of the label assignment information management area is 30M bytes maximum. In addition, the label assignment information management area capacity and label assignment information management area free space can be checked using a special register (SD2404 to SD2407).

Auto-tracking when the label assignment is changed

This function is used for the external device to refer to the changed device by auto-tracking when the device assigned to the controller label is changed. There is no need to change the label settings on the external device side.

The following table lists the necessity of changing the external device side in the label change content.

○: No need to change the external device side. ×: Need to change the external device side

Controller label change content	Whether the external device side needs to be changed	
	Necessity	Description
Changing the label assignment destination device	○	There is no need to change the label settings on the external device side.
Changing the label data type	×	Whether or not an external device referencing a label whose data type has been changed is treated as a label communication error depends on the specifications of the external device. However, when data specifying a label name is written, if the write data size differs from the data type, a label communication error will occur. The setting of the external device must be changed to the same data type as the label data type changed on the controller.
Deleting the label	×	Whether an external device referencing the deleted label is treated as a label communication error depends on the specifications of the external device. The external device needs to be modified so that the label deleted by the controller is not used by the program.

19.8 Precautions

Functions with restrictions

The following functions have restrictions on the use of labels.

Item		Description
CPU parameter	Trigger of an event execution type program	Use devices because global labels nor local labels cannot be specified for these functions.
Module parameter	• Predefined protocol support function	
	• Refresh setting of intelligent function module • Refresh setting of network module (SB/SW only)	Use module labels for these functions. Use devices if module labels are not used.
	• Refresh setting of network module (other than SB/SW)	Use devices because global labels nor local labels cannot be specified for these functions.

■Defining and using a global label with a device assigned

Define a global label following the procedure below, and use it when the functions having restriction on the use of labels are executed.

Since the device area in the device/label memory is used, secure the device area capacity.

1. Secure the device area to be used.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Memory/Device Setting] ⇨ [Device/Label Memory Area Setting]

2. Define a label as a global label, and assign a device manually.

3. Use the label defined in step 2 for the functions having no restrictions on the use of labels. Use the device assigned to the label for the function having restrictions on the use of labels.

■Copying the value of a label used to a different device

If a device cannot be assigned to a global label, copy the value of the label to a different device and use the device for the function having restrictions on the use of labels.

Since the device area in the device/label memory is used, secure the device area capacity.

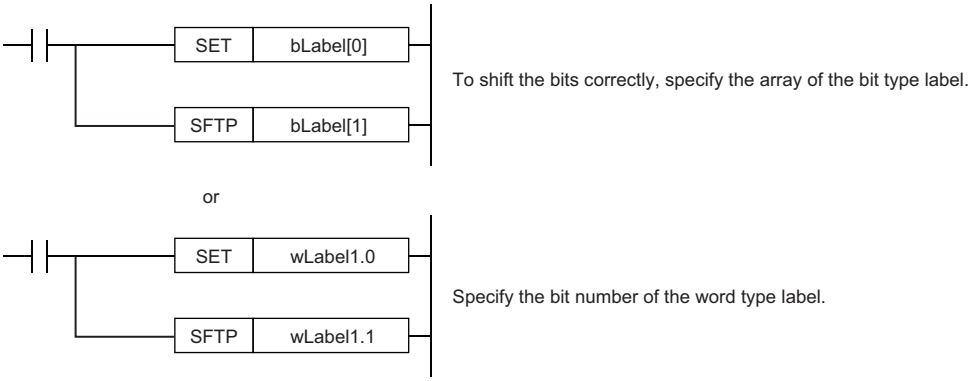
1. Secure the device area to be used.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Memory/Device Setting] ⇨ [Device/Label Memory Area Setting]

2. Create a program using the label. The following is the program example for copying the data. (The data logging function uses the data in udLabel1.)

3. Use the device where the data has been transferred in step 2 for the function having restrictions on the use of labels. (In the program example in step 2, use D0.)

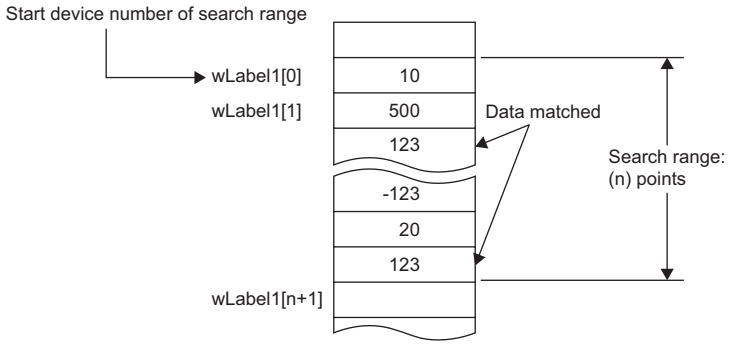
Point



- The number of steps increases because of the transfer instruction. (The scan time increases.)
- Decide the transfer instruction position considering the timing of writing data to the label and executing the function.

Precautions for creating programs

When specifying a label as an operand used in instructions, match the data type of the label with that of the operand. In addition, when specifying a label as an operand used in instructions that control continuous data, specify the data range used in instructions within the data range of the label.



Ex.

SFT(P) instruction

Ex.

SER(P) instruction

Specify a label which has a larger data range than the search range (n) points.

Restrictions on naming labels

The following restrictions apply when naming labels.

- Start the name with a character or underline (_). Numbers cannot be used at the beginning of label names.
- Reserved words cannot be used.

For details on the reserved words, refer to the following.

GX Works3 Operating Manual

Access from external devices

- Global labels to which accesses from external devices are permitted cannot be accessed while the global label setting file has been written by writing to the programmable controller or using the online change (during global label assignment information update), when the controller is powered off and on, and while the label communications have been prepared immediately after the reset. If accessed, an error occurs.
- When the global label which is set to the "Access from External Device" is deleted or the online change including label name change is executed, change the program of external devices that refer to the global label deleted/changed.
- If the number of global labels to which access from external devices is permitted increases, the time for writing data to the programmable controller, the time for the online change, or the GOT label name resolution time may increase.
- If the number of external devices accessing global labels to which access from external devices is permitted increases, the GOT label name resolution time may increase.

Label access by specifying a value outside the range of the element number

For an array type label, the label cannot be accessed by specifying a value outside the range of the element number. (Note that the range for number of elements and padding are reserved in units of 16 bits for bit type arrays. Therefore, accessing a value outside the element number range does not result in an error if it is within the range including padding.) When an element number outside the range is specified, the following occurs depending on the data type of the element number.

- When the element number is specified with a constant: An error occurs when the program is converted.
- When the element number is specified with a value other than a constant (device, label, formula): An execution error (Device, label, or buffer memory specification error) (error code: 2820H) occurs.

20 LATCH FUNCTION

20.1 Device/Label Latch

The data in each device/label of the controller is cleared to its default value in the following cases:

- When the controller is powered off and on
- When the controller is reset
- When a power failure exceeding the allowable momentary power failure time occurs

The data in each device/label with latch setting is retained even under the above described conditions. For this reason, control can be continued with the retained data even if the power of the controller is turned off or a power failure exceeding the allowable momentary power failure time occurs while the data is managed by a sequential control.

Types of latch

The following types of latch are available:

- Latch (1): Data in this range can be cleared by a latch clear operation
- Latch (2): Data in this range cannot be cleared by a latch clear operation

Applicable devices and labels

This section describes the devices/labels that can be latched.

Applicable devices

The devices below can be latched. However, local devices cannot be latched.

Device	Specification method	Applicable latch type
Internal relay (M)	Specify the latch range.	Latch (1) or Latch (2)
Link relay (B)	Specify the latch range.	Latch (1) or Latch (2)
Annunciator (F)	Specify the latch range.	Latch (1) or Latch (2)
Edge relay (V)	Specify the latch range.	Latch (1) or Latch (2)
Timer (T)/Long timer (LT)/Retentive timer (ST)/Long retentive timer (LST)	Specify the latch range.	Latch (1) or Latch (2)
Counter (C) and Long counter (LC)	Specify the latch range.	Latch (1) or Latch (2)
Data register (D)	Specify the latch range.	Latch (1) or Latch (2)
Link register (W)	Specify the latch range.	Latch (1) or Latch (2)
Latch relay (L)	Specify the number of points (latch is performed the same number of times as the specified number of points).	Latch (2) only
File register (R, ZR)	Specify the number of points (latch is performed the same number of times as the specified number of points). Specify the latch range.*1	Latch (2) only

*1 When "Use Common File Register in All Programs" is enabled, any of the number of points is registered within the range for Latch (2). Also, the range can be specified in "Latch (2)" of "Latch Range Setting" (values out of the specified range are cleared to 0).

Applicable labels

The labels below can be latched.

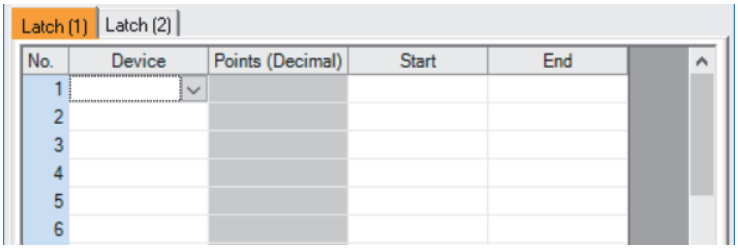
Label type	Class	Data type
Global label	VAR_GLOBAL_RETAIN	Primitive data type, array, structure
Local label of a program block	VAR_RETAIN	
FB local label	VAR_RETAIN	
	VAR_OUTPUT_RETAIN	
	VAR_PUBLIC_RETAIN	

Setting latch on devices

Multiple latch ranges can be set for a device type. A total of 32 latch ranges of latch (1) and latch (2) can be set. However, the ranges of latch (1) and latch (2) must not overlap.

Setting a latch range

Set the device to latch, its range, and the latch type.



Operating procedure

"Device Setting" window

Item	Symbol	Latch (1)	Latch (2)
Input	*X*		
Output	Y		
Internal Relay	M	No Setting	No Setting

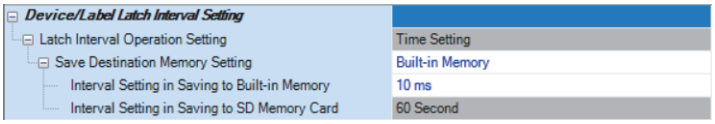
"Latch Range Setting" window

1. Click "Detailed Setting" on the "Device Setting" window.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Memory/ Device Setting] ⇨ [Device/Label Memory Area Setting] ⇨ [Device/Label Memory Area Detailed Setting] ⇨ [Device Setting] ⇨ <Detailed Setting>

2. In the "Device Setting" window, select the type of latch for the target device. The "Latch Range Setting" window is displayed.

3. Check the tab for the latch type, select the device to set and set the latch range (Start, End).



Device/label latch interval setting

Set the latch interval operation (☞ Page 421 Device/label latch interval setting).

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Memory/Device Setting] ⇨ [Device/Label Latch Interval Setting]

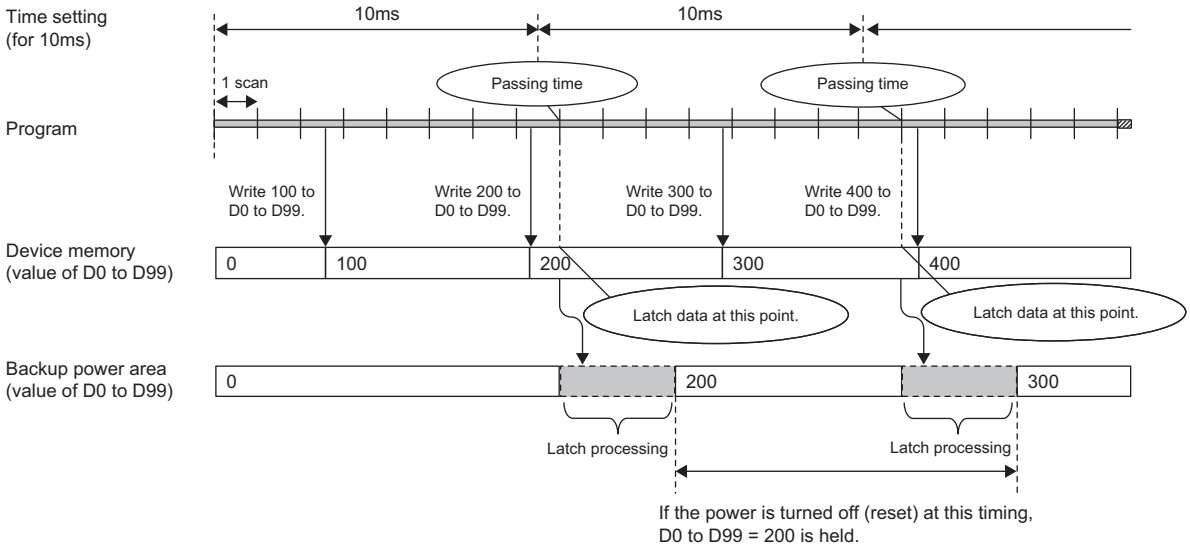
Operating procedure

"Device/Label Latch Interval Setting" window

1. In "Latch Interval Operation Setting", select the timing of the latch processing.

Displayed items

Item	Description	Setting range	Default
Latch Interval Operation Setting	Sets the timing of the latch processing.	Time Setting	Time Setting
Save Destination Memory Setting	Selects the save destination memory for the device and label for which the latch setting has been made. • Select "Built-in Memory" if latching at high speed is desired. However, there is a limit to the latch capacity. For the latch capacity, refer to the following. ☞ Page 423 Number of points that can be latched • Select "SD Memory Card" if latching more devices and labels is desired.	• Built-in Memory • SD Memory Card	Built-in Memory
Interval Setting in Saving to Built-in Memory	Use this setting when latching to internal memory.*1	1 to 2000ms (in units of 1ms)	10ms
Interval Setting in Saving to SD Memory Card	Use this setting for latching at fixed time intervals.*1	1 to 3600s (in increments of 1s)	60s



*1 For executing latch processing, the save time varies depending on the changed volume to be latched. (The more latch devices changed per scan, the longer it takes to save.) As a result, if execution is not possible at the set time interval, the latch processing is executed at the best possible interval for the system.
The current latch processing interval and the maximum latch processing interval can be checked using the special register. (☞ Page 424 Related special relay/special register areas)

■Timing of the latch processing

The timing of the latch processing is determined based on the effective range of the latch interval setting and the operation setting for the specified latch interval (☞ Page 420 Device/label latch interval setting)

• When set to "Time Setting"

Latch processing is started in the END processing executed after the set time. Since latch processing is performed asynchronously with the sequence program, the extension of scan time can be minimized.

Point

• The more the latch points, the more it takes to complete the latch processing. If the set time elapses while latch processing is still executing, the next one is executed in the END processing that follows the completion of the previous latch processing. Set a latch interval longer than the latch processing time so that the specified time does not elapse during latch processing. For the latch processing time, refer to the following.

☞ Page 1996 Latch area

• If the latch interval is shorter than the scan time, latch timing occurs more than once within one scan. However, latch processing is executed once during the END processing.

■Save destination memory

• If the save destination is "Built-in Memory"

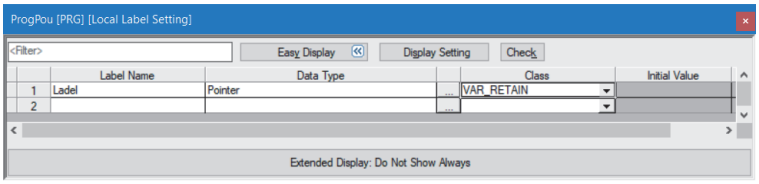
Latch processing is executed during the END processing, which can always be executed.

Note that the time required for latch processing varies depending on the number of changed latch targets.

• If the save destination is "SD Memory Card"

The data saved to the SD memory card can be restored only to controllers with the same latch range setting. If the latch range setting is different, the data will not be restored. For details, refer to the following.

☞ Page 425 Precautions



Even if the save destination is set to "SD Memory Card", the special relay and special register are saved to the built-in memory. Therefore, even if the data is restored to the controller with the same latch range setting, the data cannot be restored.

Setting latch on labels

This section describes latch setting on labels.

Operating procedure

Label edit window

"Device/Label Memory Area Detailed Setting" window

1. In the label edit window, specify "RETAIN" for label attribute.

2. There are two types of latch for labels: latch (1) and latch (2). Select one. The selected latch type is applied to labels of all latch attributes.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [Memory/Device Setting] ⇨ [Device/Label Memory Area Setting] ⇨ [Device/Label Memory Area Detailed Setting] ⇨ [Latch Type Setting of Latch Type Label]

Clearing latch range data

Latch range data is cleared by either of the operations below. (☞ Page 332 Memory Operation)

- Latch clear: Performed from the engineering tool. (GX Works3 Operating Manual)
- Latch clear by program: Execute the RST instruction for latched devices, or clear by transferring K0 by using the MOV or FMOV instruction.

Number of points that can be latched

The following table lists the latch capacity when the built-in memory or SD memory card is used.
If the save destination memory setting is set to "Built-in Memory", there is a limit on the data capacity that can be latched. Therefore, do not let the total latch size of the number of latch relay points, the device latch range setting (except for latch relay), and latch label area capacity set by this function exceed the latch capacity described below.

Conditions	Model	Latch capacity*1
When the built-in memory is used	MXR500-128, MXR500-256	1214K words
	MXR300-16, MXR300-32, MXR300-64	896K words
When the SD memory card is used	MXR500-128, MXR500-256	10238K words
	MXR300-16, MXR300-32, MXR300-64	8190K words

*1 The maximum total capacity of the number of latch relay points, devices that the latch range is set (except for latch relay), and latch labels. For the available setting range of device/label memory, refer to the following.
☞ Page 210 Hardware specifications

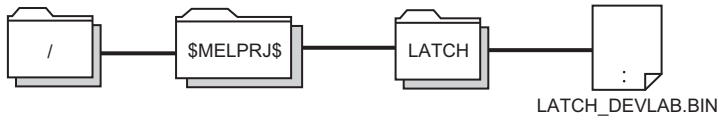
An error occurs if the size exceeds the limit that can be latched when the power turns off and on or the status changes from STOP to RUN. When an error occurs, latch processing is not performed for all devices and labels.
In the RUN state, a file register written externally by FTP transfer and other operations is not latched.
The calculation method for the latch size is as follows.

α^{*1} = ((M1 + M2 + (M3 × 2)) ÷ 16) + (M4 + (M5 × 4) + (M6 × 2)) + M7 [Word]

Variable name	Description
α	Latch size
M1	Number of M, B, F, and V points in the latch range setting
M2	Number of L points in the device setting
M3	Number of T, ST, C, and LC points in the latch range setting
M4	Number of D, W, ZR, T, ST and C points in the latch range setting
M5	Number of LT and LST points in the latch range setting
M6	Number of LC points in the latch range setting
M7	Latch label area capacity in the label area setting

*1 In division calculation, values after the decimal point are rounded up.

When SD memory card is specified



File name

If "SD Memory Card" is specified in the save destination memory setting, the latch device/label file will be saved to the SD memory card.

File type	File name	Extension	Description
Latch device/label file	LATCH_DEVLAB	BIN	The device/label data that has been latched is stored.

Folder configuration

The following figure shows the folder structure in the SD memory card when "SD Memory Card" is specified in the save destination memory setting.

Error processing

If "SD Memory Card" is specified in the save destination memory setting, an error (continuation error) will occur if the SD memory card is not inserted when latch processing starts or if the write protect switch of the SD memory card is locked (write inhibited). The same error will occur if the SD memory card is disabled by SM606 (SD memory card forced disable instruction) during latch processing.

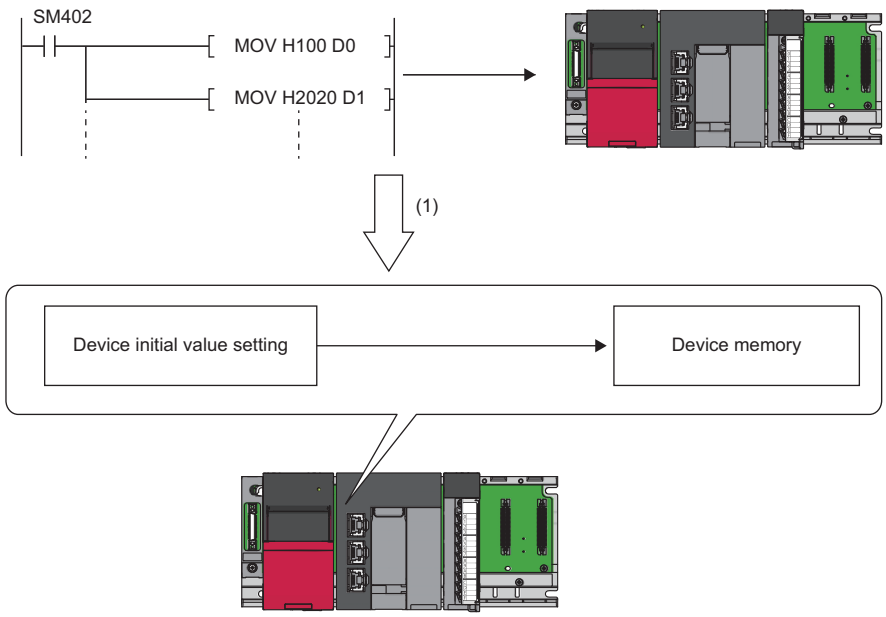
The error above is detected only the first time writing to the SD memory card fails. If writing to the SD memory card becomes possible after error handling, latch processing resumes.

Related special relay/special register areas

The following lists the related special relay area.

Special relay	Name
SM4102	Max latch interval time clear request
SM4098	Latch save completion flag after latch setting change

The following lists the related special register areas.



Special register	Name
SD4100 SD4101	Current latch interval time
SD4102 SD4103	Max latch interval time

Precautions

- When the latch range setting and the device/label latch interval setting are changed, a parameter error (error code: 2223H) occurs after the CPU parameters are written to the controller. Therefore, check the completion of latch save in SM4098 (Latch save completion flag after latch setting change) and turn the power off and on or change the operating status from reset to reset clear. If power-off/reset operation is performed after writing parameters but before latch saving is completed, the latch range setting of CPU parameters will not match the latch range setting held in the saved data when power-on or reset clear is performed, or the latch data will not exist in the save destination memory set in the device/label latch interval setting. As a result, the latch data will be discarded and the value of the device with latch setting will not be restored. (Latch relay and latch label also cannot be restored.)
- When the latch label area capacity is changed, all data must be rebuilt (reassigned). As the device/label is initialized when a reset is performed or the power is turned off and on (the initial value is reflected if the initial value is set, or the value is cleared to zero if no initial value is set) after the CPU parameters are written to the controller, the latch label value will not be restored. In addition, if the number of device points in latch relay or the latch label area capacity is changed, or if the latch save destination memory is set to "SD Memory Card", the latch device/label value will not be restored when a reset is performed or the power is turned off and on after the CPU parameters are written to the controller. (The initial value is reflected if the initial value is set, or the value is cleared to zero if no initial value is set.)
- If the number of device points in the latch relay is changed, or if the latch save destination memory is set to "SD Memory Card", the latch device/label value will not be restored when the power is turned off and on or when the operating status changes from reset to reset clear after the CPU parameters are written to the controller. (The initial value is reflected for the device/label whose initial value is set, and the value is cleared to zero for the device/label whose initial value is not set.)
- Latch data is not guaranteed if a power or cable disconnection occurs during write operation to the programmable controller and the online change. Execute the write operation to the programmable controller and the online change again.
- If a latch-specified device is used in a sequence program, when using a word device as 32-bit data, specify a device number that is a multiple of 2. When using a word device as 64-bit data, specify a device number that is a multiple of 4. Failure to do so may cause data inconsistency of the latched data.

21 DEVICE/LABEL INITIAL VALUE SETTINGS

This function sets the initial values of devices and labels used in the program directly (not via the program) to the devices, labels, and buffer memory areas of intelligent function modules.

(1) If device initial values are used, a program to set data to the devices becomes unnecessary.

21.1 Setting Device/Label Initial Values

This section describes the settings required to use device/label initial values.

Setting device initial values

This section describes the settings of device initial values.

Setting procedure

The procedure for using device initial values is as follows.

1. First, the user must create a device initial value file and an initial label value file. To set initial values to a local device, create a device initial value file with the same name as the program which sets these values, and specify the range of the values. To set initial values to a global device, create a device initial value file (with any name) which sets these initial values, and specify the range of the values.
2. On the device memory, set up device initial value data within the range specified in the device initial value file.

📖 GX Works3 Operating Manual

3. In the "Device Memory Register Diversion", select the device memory which was set up in Step 2. Setting "Device Memory Register Diversion" enables data set up on the device memory to be used as device initial values for the device which is specified in the device initial value file.

📖 GX Works3 Operating Manual

4. Configure CPU parameters. (☞ Page 427 Initial value setting)
5. Write the set device initial value file and the CPU parameter to the controller.

📖 GX Works3 Operating Manual

6. The data in the specified device initial value file is automatically set to the specified device or buffer memory of the intelligent function module when the controller is powered off and on, reset, or the status changes from STOP to RUN.

Initial value setting

Configure the initial value setting.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [CPU Parameter] ⇨ [File Setting] ⇨ [Initial Value Setting]

Window

Displayed items

Item	Description	Setting range	Default
Target Memory	Sets the storage memory for the device initial value file, initial global label value file, and initial local label value file.	• Program Memory • SD Memory Card*2	Program Memory
Setting of Device Initial Value Use Or Not	Selects whether or not to use device initial values.*3	• Not Use • Use	Not Use
Global Device Initial Value File Name	Sets the name of the initial global device value file.*1	60 characters or less	—
Device/Label Initial Value Reflection Setting at STOP to RUN	Enables or disables the device/label initial value reflection at status change from STOP to RUN.	• Enable • Disable	Disable

*1 If nothing is specified, initial global device values are not applied.

*2 If the free space in the program memory is not enough, select "SD Memory Card" in "Target Memory" and write the initial value file to the SD memory card. Note that when the label initial value is set, boot a target file from the SD memory card with the boot function. (☞ Page 325 Boot operation)

*3 When "Use" is set in "Setting of Device Initial Value Use Or Not" and the specified global device initial value file does not exist, an error occurs. If the other file (local device initial value file, global label initial value file, or local label initial value file) does not exist, an initial value is not applied, but an error does not occur.

Applicable range of device initial value files

The applicable range of device initial value files is as follows.

Target device	Applicable range
Global device	Device initial values set up in the initial value file of the global device are used.
Buffer memory	
Local device	Device initial values set up in the initial value file of the local device (Program Name.DID) are used.
File register	When a common file register is used across all programs, device initial values set up in the initial value file of the global device are used.

Number of device initial value settings and maximum range of one range

Up to 1000 ranges can be set in one device initial value file. Up to 8000 data points can be set in one range.

Setting initial label values

This section describes the settings of initial label values. For labels assigned to a device, the initial value setting follows the device initial value.

Setting procedure

The procedure for using initial label values is as follows.

1. Set up initial label values using a global label and local label.
2. Configure CPU parameters (☞ Page 427 Initial value setting)
3. The CPU parameters, programs, initial global label value file, and initial local label value file are written to the controller.

📖 GX Works3 Operating Manual

■Timing for reflecting the device/label initial value

The device/label initial value is reflected at the following timing.

- Power off to on (including from reset to reset release)
- STOP (PAUSE) → RUN

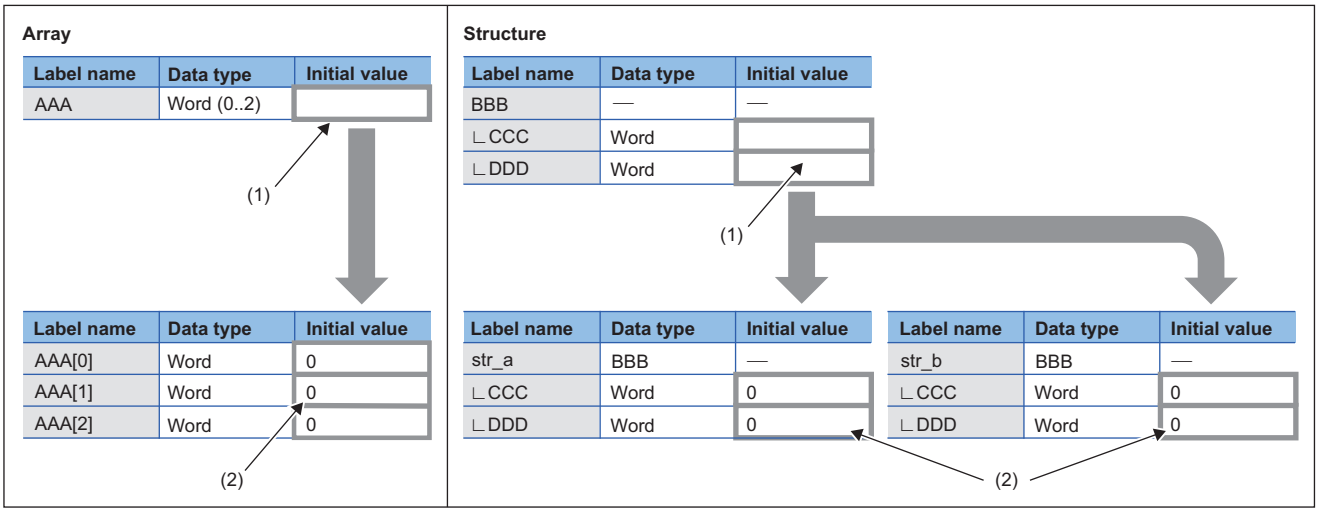
The device/label initial value is reflected at the following timing, depending on the setting of "Device/Label Initial Value Reflection Setting at STOP to RUN" in "CPU Parameter" and the non-latch/latch setting of the initial value set device/label.

CPU parameter	Device/label latch setting	Timing for reflecting the initial value	
Device/label initial value reflection at status change from STOP to RUN		Power off to on (including from reset to reset release)	STOP (PAUSE) → RUN
Disable	No latch	Reflected	Not reflected*1
	Latch	Not reflected*1	Not reflected*1
Enable	No latch	Reflected	Reflected
	Latch	Reflected	Reflected

*1 In any of the following cases, the device/label initial values are reflected even if "Device/Label Initial Value Reflection Setting at STOP to RUN" is set to "Disable".
· After all data is rebuilt and the data is written to the programmable controller
· After the device/label clear operation is executed

Initial value setting of arrays and structures

The following initial values can be set for each array element or structure instance.

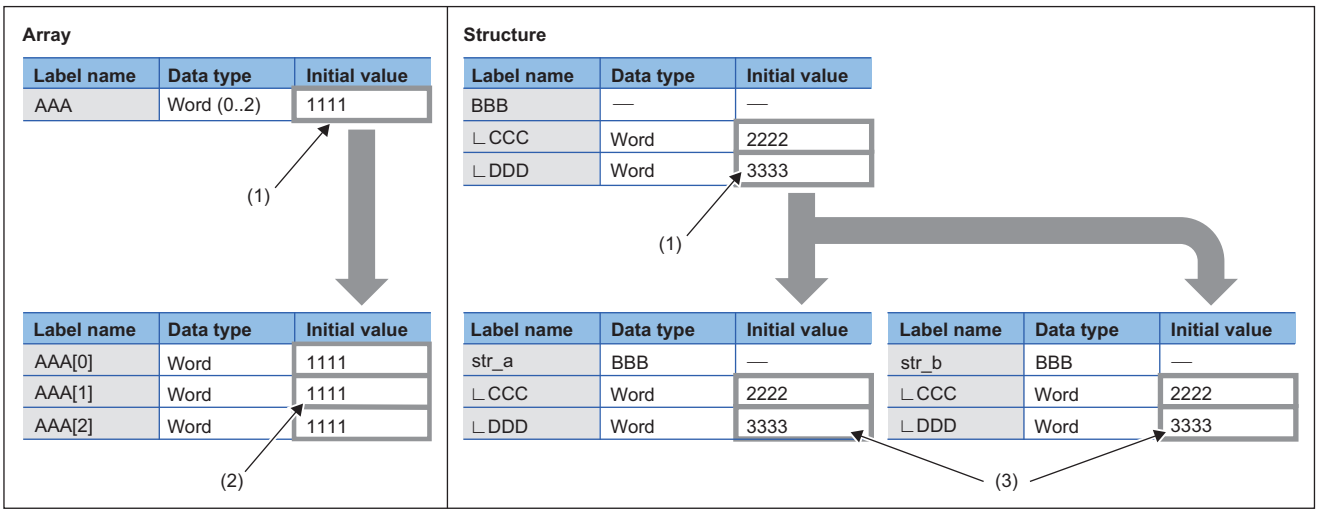


- Initial value unset
- Setting with the global label settings
- Setting with the label initial value settings

Point

When "setting with the label initial value settings" is used, the option settings in the engineering tool must be enabled.

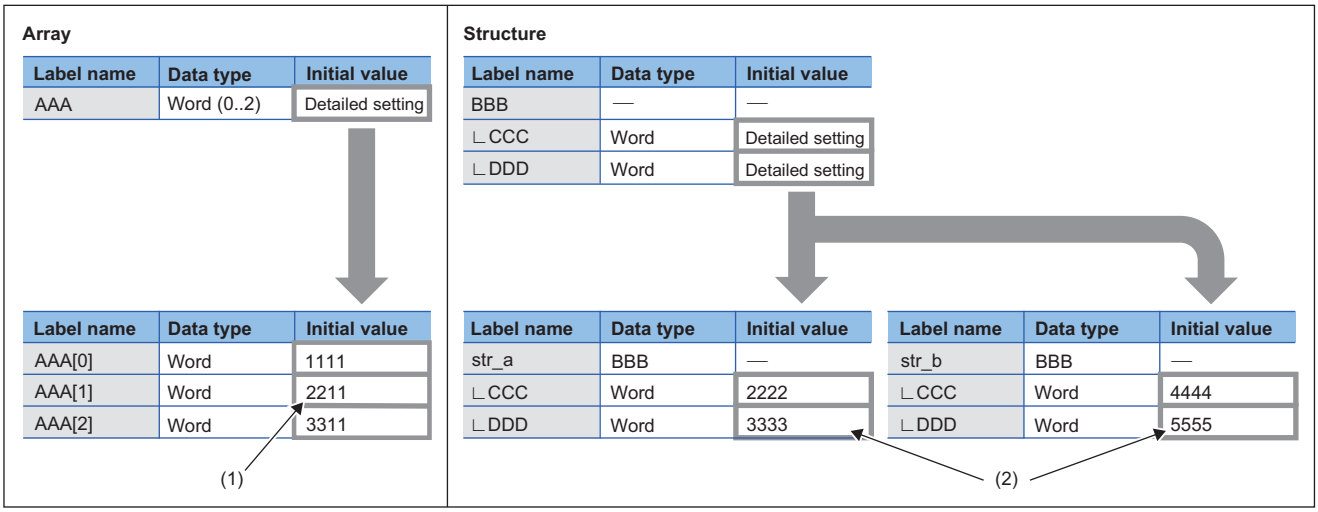
■Initial value unset



"Initial value unset" refers to the initial value determined for each data type. If no initial value is set for an array or structure, "initial value unset" is applied.

(1) An initial value is not set.
(2) Default initial value (In this case, 0 is applied.)

■Setting with the global label settings



"Setting with the global label settings" refers to the initial value set for an array or structure member. The same initial value is applied to array elements or structure members.

(1) An initial value is set.
(2) The same initial value is applied to all elements.
(3) The same initial value is applied to all instances.

■Setting with the label initial value settings

"Setting with the label initial value settings" refers to the initial value set for an array element or structure member (for each instance). A different initial value can be set for an array element or structure member (for each instance).

(1) An initial value can be set for each element.
(2) An initial value can be set for each instance.

■Order of priority for initial values

The initial label value can be set to both "setting with the global label settings" and "setting with the label initial value settings". The following table shows the order of priority of initial values applied when both are set.

Order of priority	Initial value type	Remarks
High ↑ ↓ Low	Setting with the label initial value settings	—
	Setting with the global label settings	—
	Initial value unset	This is applied when neither "setting with the global label settings" nor "setting with the label initial value settings" is configured.

As shown below, for a label where both "setting with the label initial value settings" and "setting with the global label settings" are configured (data01 in the following figure), "setting with the label initial value settings" is applied instead of "setting with the global label settings".

Structure: Define ABCD. ("Initial value not set")

Label name	Data type	Initial value
data01	Word	100
data02	Word	200
data03	Word	(No setting)

Define the global label for the structure ABCD.

Label name	Data type	Initial value
str00	ABCD	Detailed setting

Configure "setting with label initial value setting" of str00.

Label name	Data type	Initial value
str00.data01	Word	999
str00.data02	Word	(No setting)
str00.data03	Word	(No setting)

Actual initial value

Label name	Initial value
str00.data01	999 ("setting with label initial value setting" has priority.)
str00.data02	200 (Since "setting with label initial value setting" does not exist, use "setting with global label setting".)
str00.data03	0 (Since the initial value setting does not exist, use "initial value not set".)

21.2 Applicable Devices/Labels

For details on devices/labels to which initial device/label values can be set, refer to the following.

GX Works3 Operating Manual

21.3 Device/Label Initialization After Writing

When all data is rebuilt with an engineering tool, the device/label is initialized when the power is turned off and on or when the operating status changes from STOP (PAUSE) to RUN after writing data to the programmable controller (the initial value is reflected for the device/label whose initial value is set, and the initial value is cleared for the label whose initial value is not set). Also, the previous execution information of instruction executed on the rising/falling edge is initialized.

Point

The device/label is initialized only when the first write operation to the controller is performed after all data is rebuilt. Thus, to write the same project to the other controller, rebuilt all data.

Device/label to be initialized

The following are the devices/labels to be initialized.

- X, Y, M, L, B, F, SB, V, S, T, ST, LT, LST, C, LC, D, W, SW, FX, FY, FD, Z, LZ, R, ZR, RD, and all labels

21.4 Device/Label Initial Value Reflection After Device/Label Clear Operation Is Executed

When the device/label clear operation is executed from the engineering tool or using SLMP, the device/label initial value is reflected when the power is turned off and on or when the status is changed from STOP (PAUSE) to RUN after the clear operation is executed regardless of the setting of "Device/Label Initial Value Reflection Setting at STOP to RUN".

Operation to be performed

The following table lists the target operations for which the device/label initial value reflection is executed.

Category	Operation to be performed
Operation from the engineering tool	Selects "Clear other than latch" or "All clear" for the device/label memory at RUN operation in the remote operation window, and executes remote RUN.*1
	Clears the device/label values in the CPU memory operation window of the engineering tool.*2
Operation using SLMP	Executes the remote RUN command. (Only when clearing the devices outside the latch range or clearing all the devices (including the latch range) is selected for the clear mode)
	Executes the remote latch clear command.

*1 When "Not Cleared" is selected for the device/label memory, the device/label initial value reflection is not executed regardless of the setting of the rising/falling instruction execution conditions.

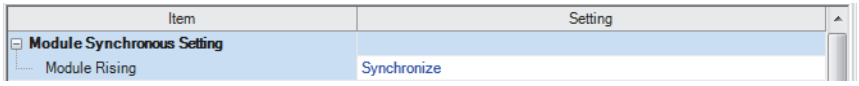
*2 When a device/label is not to be cleared (when only a file register is to be cleared), the device/label initial value reflection is not executed.

Target device/label

Regardless of the device/label clear range (non-latch/latch (1)/latch (2)), all devices/labels with initial value settings reflect the initial device/label values.

21.5 Precautions

This section describes the precautions when using the initial device/label value setting.



- When device initial values or label initial values are overlapped with the latch range, these initial values take precedence over the latch range. Therefore, even if a device or label is already latched, its values are changed to the specified initial values.
- Device/label initialization after all data is rebuilt and data is written to the programmable controller cannot be performed using the MC protocol, FTP command operations, boot function or controller backup/restoration function.
- When setting the initial value to the link device assigned to the synchronization station of the CC-Link IE TSN function, set the link refresh and then set the initial value to the refresh destination device or label. Even if U☐\G☐ (module access device) and Jn\☐ (link direct device) are specified, the initial value is not reflected in the link device. For Jn\☐ (link direct device), see the following.

☞ Page 371 Link Direct Device

- To make the controller hold a device only when its values fall into the range of device initial setting (such as module access device and link direct device), the start-up time between the device and the controller must be synchronized using the CPU parameter, "Module Synchronous Setting".

PART 9 FUNCTIONS

This part consists of the following chapter.

22 FUNCTION LIST

22 FUNCTION LIST

This chapter describes the function list of the controller. For details, refer to the references for each function.

Function	Description	Reference
Motion control	Describes the settings, functions, operation cycle, and each control for performing the motion control.	Page 434 Motion Control
CC-Link IE TSN	Describes the cyclic transmission, transient transmission, and other functions of CC-Link IE TSN.	Page 437 CC-Link IE TSN
Ethernet	Describes each communication using Ethernet. (SLMP, predefined protocol, FTP, OPC UA, and others)	Page 438 Ethernet
Data collection	Describes how to collect device values at a specified interval or at a desired timing.	Page 439 Data Collection
Security	Describes how to prevent unauthorized access and data outflow.	Page 439 Security

22.1 Motion Control

Function		Description	Reference
Axis management	Technical units	Sets the position command unit and the velocity command unit used in the motion control for the unit setting. Since the unit can be specified freely depending on the control target, intuitive programming and monitoring are available.	Page 490 Units
	Servo ON/OFF	Executes servo ON/OFF of the real axis connected to the motion system. The real axis can be operated by servo ON.	Page 501 Servo ON/OFF
	Follow up	Reflects the input (current position) from the axis-assigned device station in the set position of the axis.	Page 504 Follow Up
	Absolute position control	Restores the current position of an axis.	Page 510 Absolute Position Control
Operation cycle		In the motion system, performs operation processing related to the motion control in the fixed cycle (motion operation cycle).	Page 522 OPERATION CYCLE
Start and stop	Start	Starts motion control.	Page 543 Start
	Retrigger/continuous update	Changes the control of the ongoing FB with a retrigger/continuous update. With a retrigger/continuous update of the FB, input variables can be imported again to the on-going FB instance without interrupting operation.	Page 546 Retrigger/Continuous Update
	Multiple start (buffer mode)	Executes multiple motion control FBs continuously without stopping by executing the motion FB of another instance to the axis and the axes group that are executing the motion control FB.	Page 547 Multiple Start (Buffer Mode)
	Stop	Stops motion control.	Page 578 Stop
	Forced stop	Stops axes by the forced stop signal.	Page 609 Forced Stop
Homing	Driver homing method	Switches the drive unit to Homing mode, and executes homing based on the positioning pattern set on the drive unit side.	Page 620 Driver homing method
	Data set homing method	Executes the homing to a virtual axis and a real axis that does not have the home position information in the device station side. It is completed in the motion system, and external signals or others are not used.	Page 623 Data set homing method
Axis control	Single axis positioning control	Executes positioning to the specified position by using address information.	Page 627 Single Axis Positioning Control
	Single axis speed control	Executes the speed control for the specified axis with the specified speed. For speed control excluding position loop, refer to the following. ☞ Page 715 Velocity Control	Page 629 Single Axis Speed Control
	Single axis manual control	Executes the random positioning operation by inputting a signal from an external device.	Page 631 Single Axis Manual Control
	Multiple axes positioning control	Uses address information and executes positioning to the specified position using interpolation control.	Page 636 Multiple Axes Positioning Control

Function		Description	Reference
Direct control	Absolute position follow-up control	Changes the target position of the absolute position by restart/ continuous update, and performs positioning control without completing the instruction.	Page 712 Absolute Position Follow-up Control
	Velocity control	Switches the drive unit control mode to the cyclic synchronous velocity mode (csv), and performs control excluding the position loop. For speed control including position loop, refer to the following. ☞ Page 629 Single Axis Speed Control	Page 715 Velocity Control
	Torque control	Switches the drive unit control mode to the cyclic synchronous torque mode (cst), and performs control.	Page 726 Torque Control
	Pressure control	Switches the drive unit control mode to the cyclic synchronous pressure mode (cspr), and performs control.	Page 742 Pressure Control
Motion cyclic control	Motion cyclic positioning control	Switches the drive unit control mode to the cyclic synchronous position mode (csp), and sends the target position.	Page 761 Motion Cyclic Positioning Control
	Motion cyclic velocity control	Switches the drive unit control mode to the cyclic synchronous velocity mode (csv), and sends the target velocity.	Page 768 Motion Cyclic Velocity Control
	Motion cyclic torque control	Switches the drive unit control mode to the cyclic synchronous torque mode (cst), and sends the target torque.	Page 774 Motion Cyclic Torque Control
Synchronous control	Cam operation	Operates by synchronizing the slave axis with the master axis based on cam table.	Page 784 Cam Operation
	Gear operation	Sets the speed ratio between the master axis and the slave axis, and starts gear operation.	Page 816 Gear Operation
	Addition/Subtraction positioning	Combines the movement amount of two axes and transmits.	Page 819 Addition/Subtraction Positioning
Operation profile data		Performs opening profile for the cam and reading/writing for the cam.	Page 824 OPERATION PROFILE DATA FUNCTION
Advanced synchronous control		Advanced synchronous control can be achieved using software instead of controlling mechanically with gears, clutches, speed change gears, cams, or others.	Page 889 ADVANCED SYNCHRONOUS CONTROL
Functions related to position	Current position change function	Changes the set position and cumulative current position to any address.	Page 1054 Current Position Change Function
	Command in-position	Checks the remaining distance to the target position, and turns the command in-position flag to TRUE. The command in-position flag is used as a front-loading signal indicating beforehand the completion of the control.	Page 1059 Command In-position
	Software stroke limit	Sets an address as the movable range. Even if a movement command to the address outside the setting range is issued, the command will not be executed. By not executing the command outside the movable area, even if an incorrect command or unexpected operation occurs, the system will not operate out of the movable area and damage to the machine can be prevented.	Page 1061 Software Stroke Limit
	Hardware stroke limit	Limit switches are set at the upper/lower limit of the physical movable range, and the control is stopped by the input of a signal from the limit switch. Damage to the machine can be prevented by stopping the control before the upper/lower limit of the physical movable range is reached.	Page 1069 Hardware Stroke Limit
Functions related to speed	Acceleration/deceleration processing function	Adjusts the acceleration/deceleration of each motion control to the acceleration/deceleration curve suitable for device.	Page 1078 Acceleration/ Deceleration Processing Function
	Speed limit	Limits the command velocity to a value within the speed limit value setting range when the command velocity during control exceeds the speed limit value. By limiting the command velocity within the preset velocity limit value setting range, even if an incorrect command or unexpected operation occurs, damage to the machine can be prevented.	Page 1112 Velocity Limit
	Override function	Changes the target velocity and the target acceleration/deceleration during the execution of the control by setting the override coefficient.	Page 1116 Override Function
Functions related to torque	Torque limit	Limits the generated torque to a value within the torque limit value range when the torque generated in the servomotor exceeds the torque limit value. It controls the operation so that unnecessary force is not applied to the load and machine by limiting the generated torque.	Page 1124 Torque Limit
	Torque limit value change function	Changes the torque limit value during control.	Page 1127 Torque Limit Value Change Function

Function		Description	Reference
Compensation function	Driver unit conversion function	Converts the machine feed value to the driver command value and passes it to the target position (Target position). Also, this function converts the current position (Position actual value) of the drive unit and calculates the actual position.	Page 1129 COMPENSATION FUNCTION
Command filter	Smoothing filter	Used to suppress load-side vibration, such as work-side vibration and base shake. Frequencies higher than the set frequency can be removed.	Page 1134 Smoothing Filter
	Direction limit filter	Restricts the movement of the slave axis to one direction relative to the movement of the master axis. This helps to avoid reverse operation caused by machine vibration or other factors.	Page 1137 Moving Direction Restriction Filter
	Speed limit filter	Limits a speed of axis. The speed input by the master axis can be limited to the specific speed and can be output to the slave axis.	Page 1138 Speed Limit Filter
	Backlash compensation filter	Compensates amount of mechanical backlash (play). Each time the movement direction changes, outputs the extra commands equivalent to the set up backlash compensation amount.	Page 1139 Backlash Compensation Filter
Input variable change in execution		Changes input variables during control. In the control whose start condition is Execute command (Execute), data such as Target position (Position) and Velocity (Velocity) can be re-imported without interrupting the operation by Execute command (Execute) retrigger.	Page 1146 INPUT VARIABLE CHANGE IN EXECUTION
External signal selection		Sets I/O signals to be used in various control.	Page 1154 EXTERNAL SIGNAL SELECTION
Touch probe		Records (latches) any data at trigger input signal detection.	Page 1166 TOUCH PROBE
Digital cam switch		Digital cam switch outputs the on/off signals according to a value of any data (data source).	Page 1175 DIGITAL CAM SWITCH
Axis emulate		Performs axis control on the real axis without connecting any device station. When using the emulate function, even if the device station is not connected, the axis can be operated virtually (regarded as it is connected). This function enables to debug the user program at the start-up of the device or verify the positioning operation.	Page 1186 AXIS EMULATION
Axis control wait		Starts the axis operation of the simultaneously-started motion FBs immediately at the input timing of the execution permission signal.	Page 1190 AXIS CONTROL WAIT

22.2 CC-Link IE TSN

Cyclic transmission

This function allows periodic data communications among stations on the network using link devices.

Function		Description	Reference
Communications using RX, RY, RWr, and RWw		Communicates data in units of bits and words between the master station and device station.	Page 1235 Communications Using RX, RY, RWr, and RWw
Link refresh		Automatically transfers data between devices in the CPU function part and link devices in the CC-Link IE TSN function part.	Page 1236 Link Refresh
Direct access to link devices		Directly reads/writes the corresponding data from/to link devices of the CC-Link IE TSN function part using the program.	Page 1241 Direct Access to Link Devices
Cyclic data assurance		Assures the cyclic data integrity in units of 32 bits or station-based units.	Page 1243 Cyclic data assurance
Communication cycle coexistence		When device stations with different communication cycles are included in the network, multiple communication cycles according to each device station are used for communications.	Page 292 Communication cycle coexistence
I/O maintenance settings	Output hold/clear setting during controller STOP	When the CPU/motion function of the controller is changed from RUN to STOP, the output is forcibly held or cleared.	Page 1247 I/O Maintenance Settings
	Data link faulty station setting	Select whether to hold or clear input from a disconnected station to the controller.	
	Controller error output mode setting	When stop error of the CPU/motion function of the controller occurs, the output is forcibly held or cleared.	
CANopen communications		Controls a servo amplifier that supports the CANopen profile.	Page 1251 CANopen Communications

Transient transmission

This function is used for data exchange at any timing.

Function		Description	Reference
Communication by a dedicated instruction		Reads/writes data from the master station to the devices in the controller on a remote station or the buffer memory areas of a remote station by the dedicated instructions.	MELSEC MX Controller MX-R Model Programming Manual
Communications using the SLMP		Reads/writes data from external devices such as the network module, a personal computer, and HMI (Human Machine Interface) to the devices of the controller on the master station and the buffer memory areas of the remote station via an SLMP.	Page 1254 Communications Using the SLMP
Routing	Routing setting	Sets the communication path required for transient communication to the stations on the different network.	Page 1255 Routing
	Dynamic routing	Generates the communication path required for transient communication to the stations on the different network.	

Others

Function	Description	Reference
Reserved station setting	A reserved station is a device station that is set in the parameters and included as a station in the network when its number is counted. This station is reserved for network extension in the future, and thus the station is not actually connected, and is not detected as a faulty station despite being not connected.	Page 1257 Reserved Station Setting
Error invalid station setting	An error invalid station is a device station that is set to be not detected as a faulty station by the master station. Perform this setting when replacing a device station during a data link as well.	Page 1257 Error Invalid Station Setting
Time synchronization	Synchronizes the time of device stations with the time synchronization source (controller of the master station).	Page 1257 Time Synchronization

22.3 Ethernet

○: Supported, ×: Not supported

Function		Port for CC-Link IE TSN	Port for Ethernet	Description	Reference
SLMP communications		○	○	Reads/writes the buffer memory, devices, and others from the external device such as a personal computer or an HMI (Human Machine Interface) to an SLMP-compatible device. Data can also be read/written to a device in the controller.	Page 1260 SLMP COMMUNICATION
Simple CPU communication function		×	○	Sends/receives device data between the controller connected by Ethernet and the controller or CPU module.	Page 1266 SIMPLE CPU COMMUNICATION FUNCTION
Predefined protocol communications		×	○	Allows the communication processing only with the program of the start instruction when the protocol data for communications with the external device is registered using the engineering tool. The protocol required for communications with the external device (such as temperature controller and barcode reader) can be set easily using the engineering tool's communication protocol support function.	Page 1291 PREDEFINED PROTOCOL COMMUNICATIONS
Socket communications		×	○	Exchanges any data with an external device connected by Ethernet over TCP/IP or UDP/IP using dedicated instructions.	Page 1318 SOCKET COMMUNICATIONS
FTP function	FTP server	×	○	Reads/writes data in file units using the dedicated FTP commands from an external device.	Page 1345 FTP Server
	FTP client	×	○	Enables the controller, as an FTP client, to transfer files to an FTP server connected over Ethernet by using the file transfer function instructions.	Page 1367 FTP Client
Web server function		×	○	A function of software that provides the display of HTML and objects (such as images) in response to HTTP (Hyper Text Transfer Protocol) requests from clients (web browsers).	Page 1379 WEB SERVER FUNCTION
OPC UA server function		×	○	The external device with the OPC UA client function can access labels of the controller.	Page 1405 OPC UA Communication Function
Network setting change function		×	○	The network settings (such as IP address) of the controller is changed without changing the parameter settings.	Page 1430 Network Setting Change Function
DNS client function		×	○	Queries the DNS server for the IP address based on the server name set in the file transfer function (FTP client). Using the returned IP address, each client function performs communication processing.	Page 1437 DNS Client Function
Discard received data at CPU STOP		×	○	Discards received data from the communication destination when the status of the controller is changed from RUN to STOP (PAUSE).	Page 1438 Discard Received Data at CPU STOP

22.4 Data Collection

Function	Description	Reference
Data logging function	Collects data at a specified interval or a desired timing, and stores them as a file.	Page 1440 DATA LOGGING FUNCTION CPU Module Logging Configuration Tool Version 1 Operating Manual
Sequence scan synchronization sampling function	Collects device data of the controller in the END processing, and transfers them to the module that supports the corresponding function.	Page 1531 SEQUENCE SCAN SYNCHRONIZATION SAMPLING FUNCTION

22.5 Security

Classification	Description	Reference
Protection of information assets in the controller	Protection for information assets such as user programs stored in the controller is provided against theft, tampering, faulty operation, and unauthorized execution resulting from unauthorized access by an outsider.	Page 1536 PROTECTION OF INFORMATION ASSETS IN THE CONTROLLER
Protection of the network connected to the controller	Protection for the communication data flowing through an unprotected network connected to the controller is provided against eavesdropping and tampering resulting from unauthorized access by an outsider.	Page 1558 PROTECTION OF THE NETWORK CONNECTED TO THE CONTROLLER
Protection of operation by controller	Preset operations are performed when the controller detects an error due to receiving a DoS attack or similar issue.	Page 1591 PROTECTION OF CONTROLLER OPERATION

23 AXIS SETTING

23.1 Axis

In the motion system, the control target is called an axis. Axes are classified into real axes which target the drive units connected to the network and virtual axes which virtually generate commands and position in the motion system.

Classification	Axis type	Description
Real axis	Real drive axis	Uses the drive unit corresponding to the CiA402 drive profile connected to CC-Link IE TSN. It is counted as the number of control axes.
	Real encoder axis	Generates the current position from the synchronous encoder output pulse connected to the drive unit on the CC-Link IE TSN.
Virtual axis	Virtual drive axis	Virtually generates commands in the motion system. The real drive unit is not used.
	Virtual encoder axis	Generates the current position from the motion system variables. Used as an input axis for the single axis synchronous control.
	Virtual linked axis	Connects FBs of the single axis synchronous control. The minimum data required in the single axis synchronous control is defined.

Relevant variable

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
AxisStatus	Axis Status	Displays the current axis status. • -1: Axis variable uninitialization/Axis parameter error (Invalid) • 0: Axis disabled (Disabled) • 1: Stopping on error (ErrorStop) • 2: Decelerating to stop (Stopping) • 3: During homing (Homing) • 4: Standby (Standstill) • 5: During positioning operation (DiscreteMotion) • 6: During continuous operation (ContinuousMotion) • 7: During synchronous operation (SynchronizedMotion)

Point

The underlined part of the variables described in this manual indicates that the variable name is user-defined.

AxisName.AxisRef.AxisNo

A variable to be defined by the user

Maximum number of controlled axes

The maximum number of axes controlled by the motion system is the number of real drive axes. Other types of axes are not counted in the number of axes.

Axis type	MXR300-16	MXR300-32	MXR300-64	MXR500-128	MXR500-256
Real drive axis*1	16 axes	32 axes	64 axes	128 axes	256 axes
Virtual drive axis	Up to 10000 axes can be set. The number of settable axes depends on the setting of the system memory capacity.*2 Axis assignment can be set from the axis setting window of the engineering tool. (Up to 1024 axes can be set.) ☞ Page 466 Axis Assignment				
Virtual linked axis					
Real encoder axis					
Virtual encoder axis					

*1 When a multi-axis drive unit and a general output device are used as multiple axes, the number of those axes is counted.
(Example) For a two-axis drive unit, the number of axes counted is two axes.

*2 For the memory capacity, refer to the following.
☞ Page 471 Memory usage

If the axis setting exceeds the maximum number of controlled axes, Maximum Setting Axis Number Over Warning (event code: 00F0BH) occurs.

The axis is used as the control axis sequentially which the axis is assigned as the axis variable to the global label data and the axis which exceeds the maximum number of controlled axes turns Axis Status (AxisName.Md.AxisStatus) to "-1: Axis variable uninitialization/Axis parameter error (Invalid)" and it cannot be used for the control.

Required settings for axes

Set the following items in the axis setting window of the engineering tool to set the axes. For axis setting methods, refer to the following.

☞ Page 466 Axis Assignment

Item	Description
Axis name	Sets an axis name.
Axis No.	Sets a control axis No. of the motion system.
Axis type	Sets the axis type.
Station address	Sets the station address of a drive unit related to the axis. When a multi-axis drive unit is used, the multidrop No. needs to be set as well.
Absolute position control setting	Sets the absolute position control method of axis.
Control cycle	Sets the cycle to execute control.

Other than above items, additional parameters must be set for each axis type.

For details on parameter settings, refer to the specifications of each axis type.

Axis variables

An axis is generated/initialized by the axis setting in the engineering tool. The set axis is assigned to the global label data as an axis variable.

The axis is defined as an axis variable configured with monitor information such as parameter information, current position, and status.

An axis variable data type changes depending on the axis type.

For the setting of the engineering tool, refer to the following.

Navigation window ⇨ [Motion Setting (CPU Built-in)] ⇨ [Axis] ⇨ Right-click ⇨ [Add New Data]

Axis variable name (default)

The following names are assigned based on the setting axis No. These can be changed to an arbitrary name. For details, refer to the following.

☞ Page 466 Axis Assignment

Setting axis No.	Engineering tool default axis name
1	Axis0001
2	Axis0002
⋮	⋮
10000	Axis10000

Data type

The following data types are assigned based on the axis type. For details on data type, refer to the relevant variables of each axis type.

Axis type	Data type
Real drive axis	AXIS_REAL
Real encoder axis	AXIS_ENCODER
Virtual drive axis	AXIS_VIRTUAL
Virtual encoder axis	AXIS_VIRTUAL_ENCODER
Virtual linked axis	AXIS_VIRTUAL_LINK

Each data type has the following members.

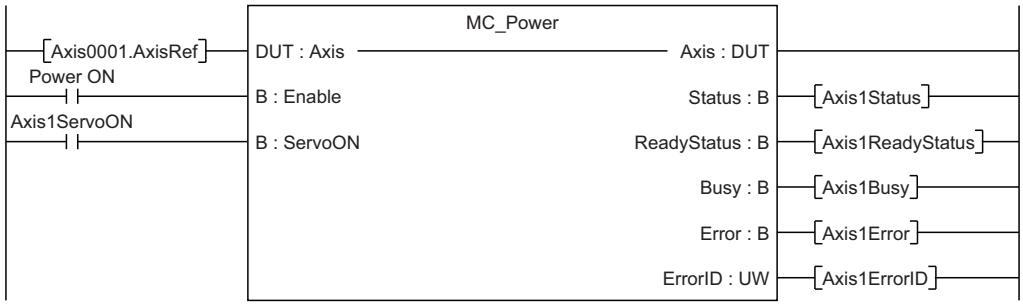
Member name	Data type	Description
AxisRef	AXIS_REF	A data structure for input/output of motion control FBs. The type is fixed regardless of the axis type.
PrConst	Differs by the axis type.	Stores the axis parameter data (constant). Opens the setting value at the axis variable initialization. Re-importing to the control data is not executed after axis variables initialization.
Pr		Stores the axis parameter data. Opens the default value at the axis variable initialization. The timing to import to the control changes depending on the parameter.
Md		Stores the axis monitor data. Data refresh is performed at a fixed interval for each monitor data.
Cd		Stores the axis control command data. Acquires the latest value every control operation cycle and uses it for the control.

Axis variable initialization timing

Axis variables are initialized at the following timing.

Timing	Processing
At power supply When the controller is reset	Refers to the global label data, and initializes all set axis variables.
When PLC READY (MotionSystem.Cd.SequenceReady) is turned on	■Uninitialized axes Refers to the global label data and initializes all axes variables. ■Initialized axes Refer to the global label data for the axis parameter data and reload again. When the parameter error occurs at loading, the axis is not deleted. At this time, built-in motion ready [X20] does not turn on. For the label initialization processing when PLC READY (MotionSystem.Cd.SequenceReady) is turned on, refer to the following. ☞ Page 426 DEVICE/LABEL INITIAL VALUE SETTINGS

For a real axis, the device network connection is required to actually operate an axis after the axis variable is initialized. If the device of the station address has been connected, it must be disconnected and then reconnected. (The axes can be emulated without network connection. (☞ Page 1186 AXIS EMULATION))



How to specify in a user program

When specifying the axis by the motion control FB, set the AXIS_REF type member (AxisName.AxisRef) of the axis variable to the I/O variables whose data type is "AXIS_REF".

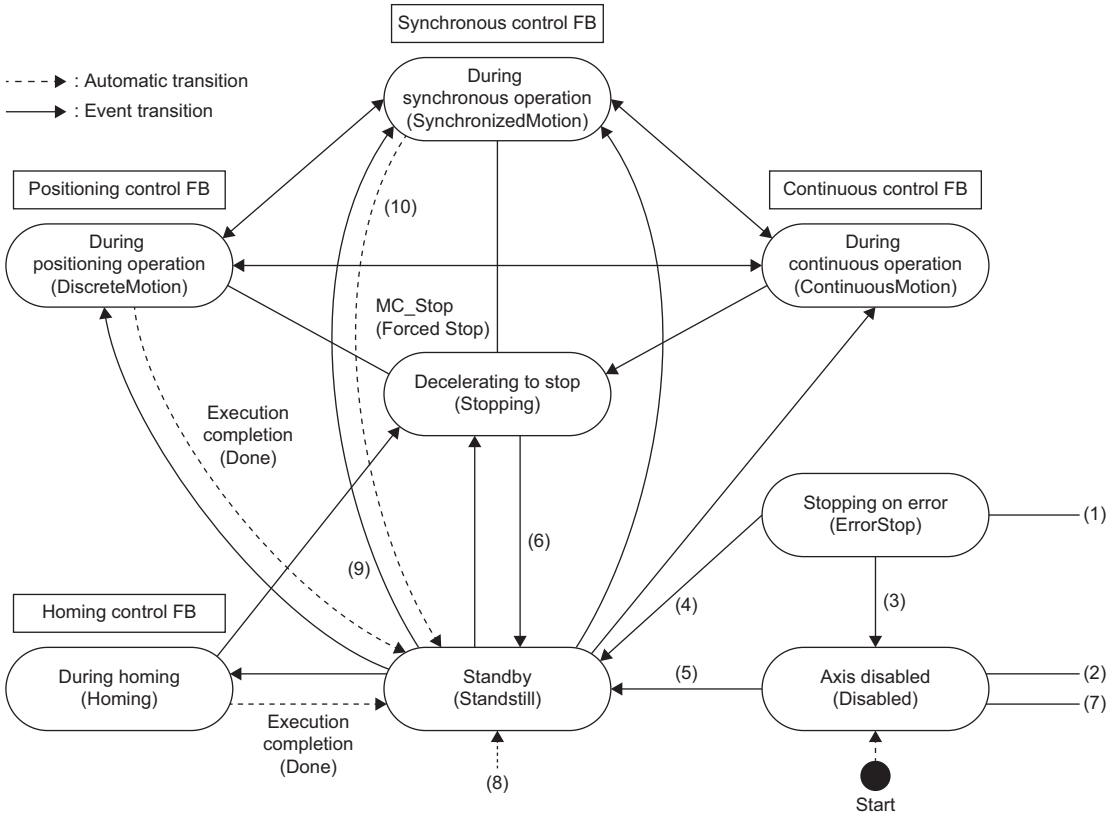
Ex.

When executing the MC_Power (Operation Available) with the following conditions:

- Axis type: Real drive axis
- Axis No.: 1
- Axis name: Axis0001

Axis status

Axis state transition



The following shows the status that a single axis can be in.

The current status can be checked in Axis Status (AxisName.Md.AxisStatus) or in MC_ReadStatus (single axis status reading).

Status	Description
-1: Axis variable uninitialization/Axis parameter error (Invalid)	Axes cannot be used in this status due to axis variable uninitialization (parameter error occurrence at an initialization or other factors).
0: Axis disabled (Disabled)	The status where the axis cannot be used. For a real drive axis, this status indicates the servo OFF stop. For a real axis, this status occurs also when the device station is disconnected from the network.
1: Stopping on error (ErrorStop)	The status where the deceleration stop or stop by error occurrence. For a real drive axis, the axis is servo ON or servo OFF depending on the error.
2: Decelerating to stop (Stopping)	The status where the deceleration stop has been executed by MC_Stop (Forced Stop). After the axis stop is completed, this status continues until the Execution command (Execute) of MC_Stop (Forced Stop) changes to FALSE. Motion control FBs cannot be executed in this status.
3: During home position return (Homing)	The status where homing has been executed in the drive unit or the motion system by the homing control FB.
4: Standby (Standstill)	The status where the motion control FB can be used. For a real drive axis, the axis is servo ON stop.
5: During positioning operation (DiscreteMotion)	The status where the positioning operation has been executed by the positioning control FB.
6: During continuous operation (ContinuousMotion)	The status where the continuous control has been executed by the continuous control FB (such as the FB of speed control and torque control) or the manual control FB.
7: During synchronous operation (SynchronizedMotion)	The status where the axis synchronizes with the master axis by the single axis synchronous control FB. The status transits to this status after the axes group set as the configuration axes changes to the "5: Operating (GroupMoving)" status.

The status transits as shown below according to the start of the motion control FB. The state transition may varies depending on the axis type. For the specifications of each axis type, refer to the following.

☞ Page 449 Axis Type

No.	State transition description
(1)	From any state, the status transits when an error occurs on the axis.
(2)	• From any state, the status transits when Enable (Enable) of MC_Power (Operation Available) is FALSE, and no error occurs on the axis. • Transits from "4: Standby (Standstill)" when Enable (Enable) of MC_Power (Operation Available) is TRUE, Servo ON request (ServoON) is FALSE, and no error occurs in the axis. • Transits when Process Selection at Servo OFF Command During Operation (AxisName.Pr.StopMode_ServoOff) is "0: Ignore (Ignore)" and Servo ON request (ServoON) of MC_Power (Operation Available) turns to FALSE from "2: Decelerating to stop (Stopping)".*1
(3)	Transits by the status error cancel for the error reset command during the servo OFF state.
(4)	Transits by the status error cancel for the error reset command during the servo ON state.
(5)	Transits when Enable (Enable) of MC_Power (Operation Available) is TRUE, Servo ON request (ServoON) is TRUE, and Operable (Status) of MC_Power (Operation Available) is TRUE.
(6)	Transits when Execution completion (Done) of MC_Stop (Forced Stop) is TRUE and Execution command (Execute) of MC_Stop (Forced Stop) is FALSE.
(7)	• From "4: Standby (Standstill)", the status transitions when the forced servo OFF is enabled by the drive unit. • From "4: Standby (Standstill)", the status transitions when the drive unit fails to communicate.
(8)	Transits automatically when the virtual axis is enabled.
(9)	Transits when the axes group used as configuration axes changes to "5: Operating (GroupMoving)".
(10)	The conditions for transition differ depending on the function. Refer to the state transition of each function.

*1 The axis status does not transit until the axis is stopped completely. After the axis stops completely, the status transits to "0: Axis disabled (Disabled)". For details, refer to the following.

☞ Page 578 Stop

Single axis status reading

Axis variables can also be read by the motion control FB.

Function block symbol	Process description
MC_ReadStatus	Acquires the state transition status of the specified axis.

For details on how to read the data using the motion control FB, refer to the following.
MELSEC MX Controller MX-R Model Programming Manual

Restriction

Before using this function, check the versions of the controller and engineering tool used. (☞ Page 2196 Added or Enhanced Functions and Supported Versions)

Precautions

Out of parameter range (axis) (error code: 1A60H) occurs if a parameter error occurs at the axis variable initialization. At this time, Axis Status (AxisName.Md.AxisStatus) will be "-1: Axis variable uninitialization/Axis parameter error (Invalid)". The monitor data and other items of the axis where "-1: Axis variable uninitialization/Axis parameter error (Invalid)" occurred are not refreshed. If the axis is specified by the user program, Out of axis No. range (error code: 1B82H) occurs.
Deleting an axis or axes group variable by writing to the controller (including online program change) causes an Invalid write to the controller (error code: 3408H). Then, the motor will immediately stop due to the setting. Note that immediate stop may damage the machine.

Relevant add-ons

The following add-ons are required to use this function.

- Axis
- MotionEngine
- NetworkDriver_CCIETSN*1
- ServoDriver_CANopen*1

*1 When using the real axis

System memory capacity

For details, refer to the following.
☞ Page 471 Memory usage

23.2 Axis Type

Relevant variables

Real drive axis data type AXIS_REAL members (excluding AxisRef)

■Axis parameter constant (AxisName.PrConst.)

Variable/structure name	Name	Details
AxisType	Axis Type Setting	Sets the axis type. ☞ Page 466 Axis type
AddressOfStation	Station Address Setting	Sets the station address (IP address) with a character string. ☞ Page 467 Station address
OperationCycle	Control Cycle Setting	Sets the control operation cycle. ☞ Page 467 Control Cycle
SlaveObject	Object Data	Sets the object of the device station. Only [OBJ] and [CONST] can be set as the data type. ☞ Page 456 Object data settings

■Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
AxisStatus	Axis Status	Displays the current axis status. • -1: Axis variable uninitialization/Axis parameter error (Invalid) • 0: Axis disabled (Disabled) • 1: Stopping on error (ErrorStop) • 2: Decelerating to stop (Stopping) • 3: During homing (Homing) • 4: Standby (Standstill) • 5: During positioning operation (DiscreteMotion) • 6: During continuous operation (ContinuousMotion) • 7: During synchronous operation (SynchronizedMotion)
UseInGroup	Using Axes Group	Displays whether the axis is being used in the axis group or not. • FALSE: Not used • TRUE: Used
Io_PosActualValue	Object Data_PosActualValue	Displays the value of object data Position actual value (6064H). ☞ Page 469 Object data settings
Io_Statusword	Object Data_Statusword	Indicates a value of object data_Statusword. Displays the value of object data Statusword (6041H). ☞ Page 469 Object data settings
Io_TargetPos	Object Data_TargetPos	Displays the value of object data Target position (607AH). ☞ Page 469 Object data settings

Real encoder axis data type AXIS_ENCODER members (excluding AxisRef)

■Axis parameter constant (AxisName.PrConst.)

Variable/structure name	Name	Details
AxisType	Axis Type Setting	Sets the axis type. ☞ Page 466 Axis type
AddressOfStation	Station Address Setting	Via drive unit: Sets the same station address as the real drive axis that the encoder is connected.
Encoder_AxisType	Real Encoder Axis Type Setting	Sets the type of the real encoder axis. • 1: Via drive unit (Drive)
Encoder_CounterDisableSignal	Counter Disabling Signal	Sets the signal to switch to the counter disable. ☞ Page 504 Follow Up

■Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
AxisStatus	Axis Status	Displays the current axis status. • 0: Axis disabled (Disabled) • 1: Stopping on error (ErrorStop) • 2: Decelerating to stop (Stopping) • 3: During homing (Homing) • 4: Standby (Standstill)
Encoder_CounterDisable	Counter Disabled	Becomes TRUE while disabling the input from the encoder. • FALSE: Counter enabled • TRUE: Counter disabled
Io_Statusword	Object Data_Statusword	Displays the synchronous encoder status emulated by the motion system.
Io_PosActualValue	Object Data_PosActualValue	Displays the input pulse value [encoder pulse unit] acquired from the synchronous encoder.
Io_PosEncoderResolution	Object Data_PosEncoderResolution	Displays the synchronous encoder resolution. Reads the value from the setting location when the drive unit is connected.

Virtual drive axis data type AXIS_VIRTUAL members (excluding AxisRef)

■Axis parameter constant (AxisName.PrConst.)

Variable/structure name	Name	Details
AxisType	Axis Type Setting	Sets the axis type. ☞ Page 466 Axis type
OperationCycle	Control Cycle Setting	Sets the control operation cycle. ☞ Page 467 Control Cycle

■Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
AxisStatus	Axis Status	Displays the current axis status. • -1: Axis variable uninitialization/Axis parameter error (Invalid) • 0: Axis disabled (Disabled) • 1: Stopping on error (ErrorStop) • 2: Decelerating to stop (Stopping) • 3: During homing (Homing) • 4: Standby (Standstill) • 5: During positioning operation (DiscreteMotion) • 6: During continuous operation (ContinuousMotion) • 7: During synchronous operation (SynchronizedMotion)
Io_TargetPos	Object Data_TargetPos	Displays a value which is converted into the command value in a driver unit from the cumulative current position.

Virtual encoder axis data type AXIS_VIRTUAL_ENCODER members (excluding AxisRef)

■Axis parameter constant (AxisName.PrConst.)

Variable/structure name	Name	Details
AxisType	Axis Type Setting	Sets the axis type. ☞ Page 466 Axis type
Encoder_CounterDisableSignal	Counter Disabling Signal	Sets the signal to switch to the counter disable. ☞ Page 504 Follow Up
Encoder_RingCout_LowerValue	Encoder Ring Counter Lower Limit Value	Sets the encoder ring counter lower limit value. ■One-word PosActualValue -32768 to 32767*1 ■Two-word PosActualValue or omits PosActualValue -2147483648 to 2147483647
Encoder_RingCout_UpperValue	Encoder Ring Counter Upper Limit Value	Sets the encoder ring counter upper limit value. ■One-word PosActualValue -32768 to 32767*1 ■Two-word PosActualValue or omits PosActualValue -2147483648 to 2147483647
SlaveObject	Object Data	Sets the object of the device station.
PosActualValue	PosActualValue	Sets the data storing synchronous encoder input. • One-word specified: -32768 to 32767 • Two-word specified: -2147483648 to 2147483647

*1 If a value outside the 1-word range is set, Out of parameter range (axis) (error code: 1A60H) occurs.

■Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
AxisStatus	Axis Status	Displays the current axis status. • 0: Axis disabled (Disabled) • 1: Stopping on error (ErrorStop) • 2: Decelerating to stop (Stopping) • 3: During homing (Homing) • 4: Standby (Standstill)
Encoder_Connected	Connection Status	Displays the virtual encoder axis connection status. • FALSE: Not connected • TRUE: Connected
Encoder_CounterDisable	Counter Disabled	Becomes TRUE while disabling the input from the encoder. • FALSE: Counter enabled • TRUE: Counter disabled
Io_PosActualValue	Object Data_PosActualValue	Displays the value [encoder pulse unit] acquired from the encoder input.
Io_PosEncoderResolution	Object Data_PosEncoderResolution	Displays the synchronous encoder resolution.

■Axis control data (AxisName.Cd.)

Variable/structure name	Name	Details
Encoder_Connect	Connection Command	The signal for enabling the connection status of the virtual encoder axis input. • FALSE: Disabled • TRUE: Enabled
Encoder_InputValue	Encoder Input Value	Sets the value sequentially used as the virtual encoder axis input value.

Virtual linked axis data type AXIS_VIRTUAL_LINK members (excluding AxisRef)

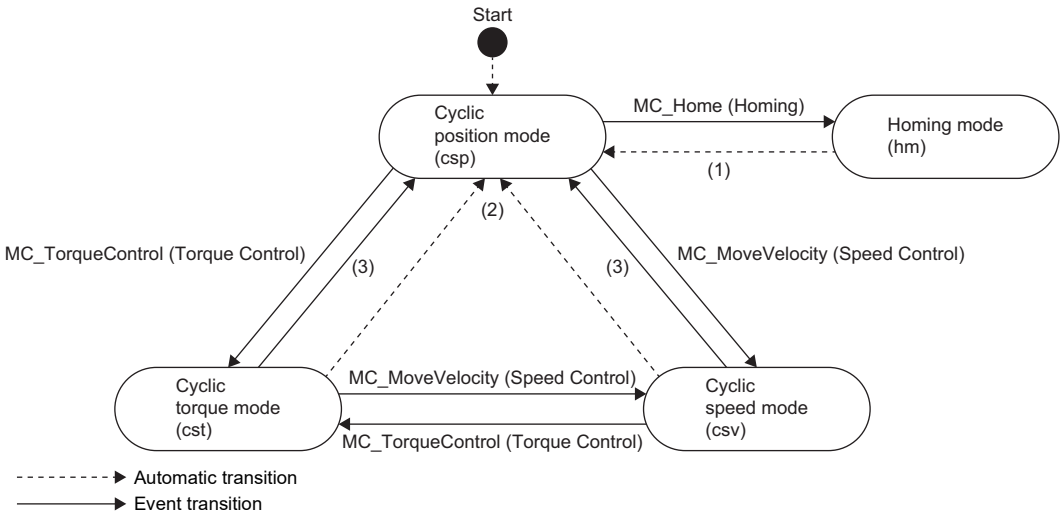
■Axis parameter constant (AxisName.PrConst.)

Variable/structure name	Name	Details
AxisType	Axis Type Setting	Sets the axis type. ☞ Page 466 Axis type
OperationCycle	Control Cycle Setting	Sets the control operation cycle. ☞ Page 467 Control Cycle

■Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
AxisStatus	Axis Status	Displays the current axis status. • -1: Axis variable uninitialization/Axis parameter error (Invalid) • 0: Axis disabled (Disabled) • 1: Stopping on error (ErrorStop) • 2: Decelerating to stop (Stopping) • 3: During homing (Homing) • 4: Standby (Standstill) • 5: During positioning operation (DiscreteMotion) • 6: During continuous operation (ContinuousMotion) • 7: During synchronous operation (SynchronizedMotion)

Real drive axis



This axis uses the drive unit which is compatible with the CiA402 drive profile connected to CC-Link IE TSN.
It is counted as the number of control axes.

Driver control mode transition

A drive unit connected as a real drive axis follows the CiA402 drive protocol, and changes the control mode according to the "Modes of operation" object output from the motion system. The drive unit inputs the current control mode as the "Modes of operation display" object in the motion system and displays it in Driver Control Mode (AxisName.Md.Driver_Mode).
The motion system supports the operation of the following control modes.
Control modes other than the ones shown below are available for some drive units. (☞ Page 2165 Driver control mode)

Supported control mode		Description	Reference
Homing mode (hm)	6: hm	Executes homing operation by a driver.	Page 620 Driver homing method
Cyclic position mode (csp)	8: csp	Executes control following the sequential positioning command from the controller in each communication cycle.	Page 710 DIRECT CONTROL
Cyclic velocity mode (csv)	9: csv	Executes control following the velocity command from the controller in each communication cycle.	
Cyclic torque mode (cst)	10: cst	Executes control following the torque command from the controller in each communication cycle.	

The control mode of the drive unit must be cyclic synchronous position mode (csp) when the unit is connected.
Control mode switching of the drive unit is executed at the same time when the motion control FB is executed. The state transition is shown below.

No.	State transition description
(1)	Transits after the axis is stopped by homing completion or error occurrence.
(2)	Transits at stop completion or error occurrence.
(3)	Transits when operation system FBs (such as positioning control FBs) are multiple started in the cyclic synchronous position mode (csp).

Parameter setting items

Set values for drive units being used as shown below.

• MELSERVO

Do not change the values from the initial values.

• Drive units other than the MELSERVO

Refer to the manuals for each drive unit.

Set values as shown in the following setting value format.

Data type	Setting value format
[OBJ]*1	[OBJ] 0xXXXXYYZZ (hexadecimal) XXXX: Specify the index. YY: Specify the subindex. ZZ: Specify the size (in bits). (Set any of 08, 10, or 20.) If the values are not set as shown in the format, Out of parameter range (axis) (error code: 1A60H) will occur.
[CONST]*2	[CONST] Constant (decimal) [CONST] 0xConstant (hexadecimal) If the values are not set as shown in the format, Out of parameter range (axis) (error code: 1A60H) will occur.
Other than [OBJ] and [CONST]	No settings are available. If settings are configured, Object Data Setting Incorrect (error code: 1AEEH) will occur.

*1 If an overlap of setting values of object data in the same axis occurs, intended data cannot be received or sent because object data and object cannot be linked with each other. Therefore, the function using the object data cannot operate normally.

*2 Regarding the object data with [CONST] set as the data type, the set constant is used for operation without using the value received via PDO from the device station. The set constant is not sent to the device station via PDO.

Precautions

If the axis parameter has an error when the controller power is turned on with the drive unit being connected, the faulty axis will not be generated, and the drive unit will be connected as a module that is not controlled by the motion system.

In this state, if the axis parameter is reviewed and the PLC READY (MotionSystem.Cd.SequenceReady) is turned on again, the axis is generated, but the drive unit cannot be connected as an axis.

To connect the drive unit as an axis, power on the controller and the drive unit again.

Real encoder axis

Generates the current position from the synchronous encoder output pulse connected to the drive unit on the CC-Link IE TSN. This will be used at the "single axis synchronous control".

This axis can control the synchronous encoder shown below as the real encoder axis.

Real encoder axis type	Description
Via drive unit	Uses the following synchronous encoder connected to the drive unit (such as the MR-J5(W)-G) corresponding to the scale measurement function as the real encoder axis. • HK-KT, HK-MT servo motor encoder

Point

When the linear encoder and phase ABZ differential output type rotary encoder are connected to the drive unit, use the encoders as virtual encoder axes. For details, refer to the following.

☞ Page 461 Virtual encoder axis

Parameter setting items

Set the following items to use the real encoder axis.

○: Necessary, △: Optional, —: Unnecessary, ●: Necessary for the same station address real drive axis

Setting item		Real encoder axis type	Reference
		Via drive unit	
Axis No.		○	Page 466 Axis No.

Real encoder axis type setting

Sets the synchronous encoder type which will be the origin of generating the real encoder axis input value.

Setting value	Description
1: Via drive unit (Drive)	Uses the synchronous encoder input value via drive unit connected to the specified drive unit as the synchronous encoder input.

To use via drive unit type, set the real drive axis of the same station address and assign the required objects listed below.

☞ Page 456 Object data settings

For details on the real drive axis setting method, refer to the following.

☞ Page 466 Axis Assignment

Station address

Depending on the real encoder axis type, set the following.

Real encoder axis type	Applicable device set as station address
Via drive unit	Drive unit connected with the synchronous encoder

For details on the setting value, refer to the following.

☞ Page 466 Axis Assignment

Object data settings

Depending on the real encoder axis type, set the following.

Real encoder axis type	Setting item	Object to be set	Description*1
Via drive unit	Real drive axis of the same station address*3	Encoder status 2	Specify the object ID storing the drive unit scale measurement function setting. • bit 0: Scale measurement function ABS system correspondent • bit 1: Scale measurement function * Valid when TRUE Reads the value from the setting location when connecting to the drive unit. When bit 1 is FALSE, Synchronous encoder via drive unit setting incorrect (error code: 1AEAH) occurs.
		Scale ABS counter*2	Specify the object ID storing the current synchronous encoder multiple revolution counter. ■Setting range Handled as -32768 to 32767.
		Scale cycle counter*2	Specify the object ID storing the current synchronous encoder position within one revolution. ■Setting range 0 to the range specified by the scale measurement encoder resolution.
		Scale measurement encoder Resolution	Specify the object ID storing the synchronous encoder resolution. The synchronous encoder with setting value 0 cannot be connected.
		Scale measurement encoder reception status*2	Specify the object ID storing the alarm information of the scale measurement encoder. • bit 0: CPU alarm • bit 1: LED alarm • bit 2: Data alarm • bit 5: Multi-revolution counter alarm • bit 6: ABS erased alarm * When TRUE, corresponding alarm occurs

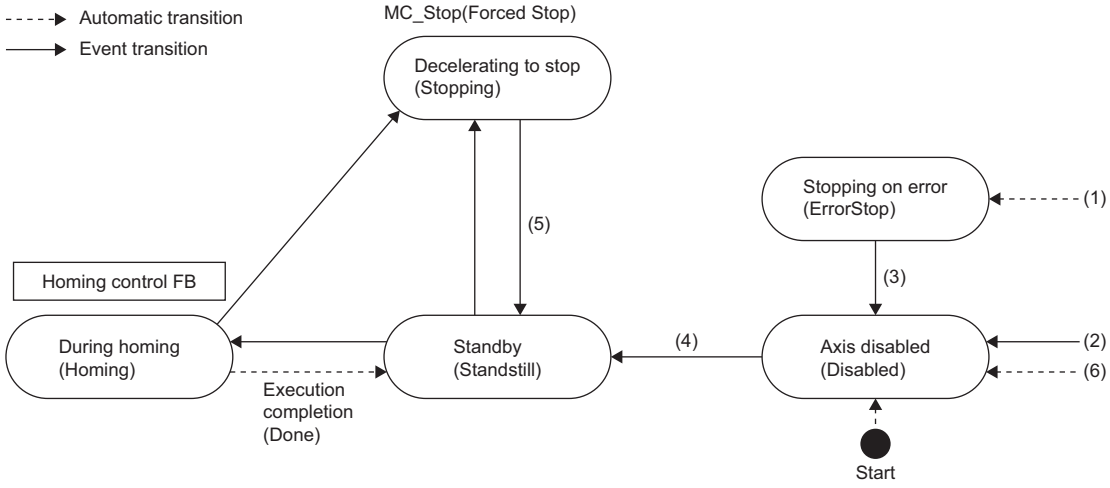
*1 For details on the setting value, refer to the following.
☞ Page 1158 TARGET_REF Structure

*2 If all of the object data are not assigned to PDO, Synchronous encoder via drive unit setting incorrect (error code: 1AEAH) occurs.

*3 If the required objects are not set for object data, Synchronous encoder via drive unit setting incorrect (error code: 1AEAH) occurs.

Functions required

The following are the functions required to use the real encoder axis.



Function		Reference	Axis type specific detailed information
Axis assignment		Page 466 Axis Assignment	—
Unit		Page 490 Units	—
Compensation function	Driver unit conversion function	Page 1130 Driver Unit Conversion Function	—
Absolute position control		Page 510 Absolute Position Control	—
Operation cycle		Page 522 OPERATION CYCLE	—
State transition	Single axis state transition	Page 457 Single axis state transition	Page 457 State transition
Follow-up (counter enabled/counter disabled)		Page 504 Follow Up	—
Servo ON/OFF		Page 501 Servo ON/OFF	—
Ring counter setting		Page 496 Positioning Range	—
Control change function	Current position change function	Page 1054 Current Position Change Function	Page 458 Control change function
Command filter	Smoothing filter	Page 1133 COMMAND FILTER	—
	Moving direction restriction filter		—

For other functions, refer to each function and check the required object data for the function. If the axis holds the required object data, the function is valid.

State transition

■Single axis state transition

The real encoder axis (via drive unit) transits to the status shown below.

No.	State transition description
(1)	Transits from any state when an error of the axis occurs.
(2)	• Transits from any state when Enable (Enable) of MC_Power (Operation Available)/MCv_AllPower (All Axes Operation Available) is FALSE and no error occurs in the axis. • Transits from "4: Standby (Standstill)" when Enable (Enable) of MC_Power (Operation Available)/MCv_AllPower (All Axes Operation Available) is TRUE, Servo ON request (ServoON) is FALSE, and no error occurs in the axis.
(3)	Transits by the status error cancel for the error reset command during the servo OFF state.
(4)	After the real drive axis with the same station address is connected, the status transits when Enable (Enable) of MC_Power (Operation Available)/ MCv_AllPower (All Axes Operation Available) is TRUE, Servo ON request (ServoON) is TRUE, and Operable (Status) of MC_Power (Operation Available) is TRUE.
(5)	Transits when Execution completion (Done) of MC_Stop (Forced Stop) is TRUE and Execution command (Execute) of MC_Stop (Forced Stop) is FALSE.
(6)	Transits from any state other than the "1: Stopping on error (ErrorStop)" status when the real drive axis which is the same station address is not to be connected.

Point

- Follow-up is executed for "4: Standby (Standstill)" or "3: During homing (Homing)".
- Follow-up is disabled in "0: Axis disabled (Disabled)", "1: Stopping on error (ErrorStop)", and "2: Decelerating to stop (Stopping)". For the set position when follow-up is disabled, refer to the following.

☞ Page 506 Disabling follow up

- When encoder alarm information is received from the real drive axis to which the encoder is connected, communication error of connected encoder (error code: 1B17H) occurs and the real encoder axis is disconnected. Check the real drive axis and remove the cause of the error, then connect the real drive axis again.

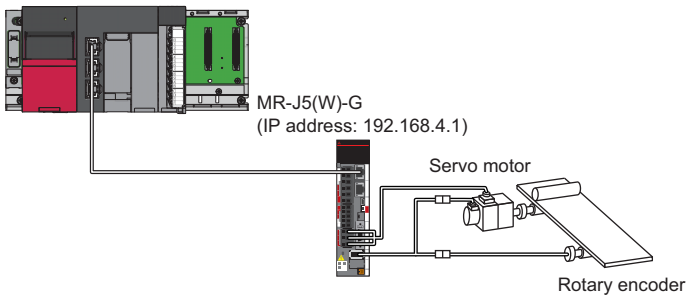
Control change function

When starting the current position change control unconditionally, use the MC_SetPosition (Current Position Change).

Point

To use the control change function by the real encoder axis, Axis Status (AxisName.Md.AxisStatus) of the real encoder axis is required to be set as "4: Standby (Standstill)" by Servo ON/OFF function.

Setting example



The setting example of the real encoder axis is shown below.

[Via drive unit]

Depending on the connected drive unit or version, available functions and encoders are restricted. For details, refer to the manuals for the drive unit used.

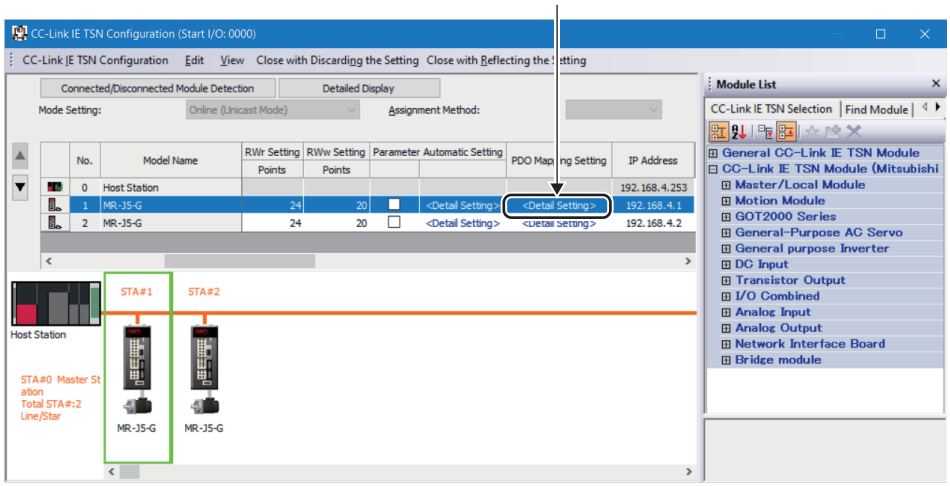
Ex.

To use the scale measurement device of real drive axis 1 (MR-J5(W)-G station address: 192.168.4.1) as the input of real encoder axis 2

■Axis setting

Setting item	Axis setting	
	Real drive axis setting	Real encoder axis setting
Axis No.	1	2
Axis type	0: Real drive axis (DriveAxis)	2: Real encoder axis (EncoderAxis)
Real Encoder Axis Type Setting	Unnecessary	1: Via drive unit (Drive)
Station address	192.168.4.1	192.168.4.1 (Specify the station address of the drive unit that the synchronous encoder is connected.)
Absolute Position Control Setting	-1: Automatic Setting (Acquire from Connected Device) (Auto)	Optional*1
Control Cycle	0	0*2

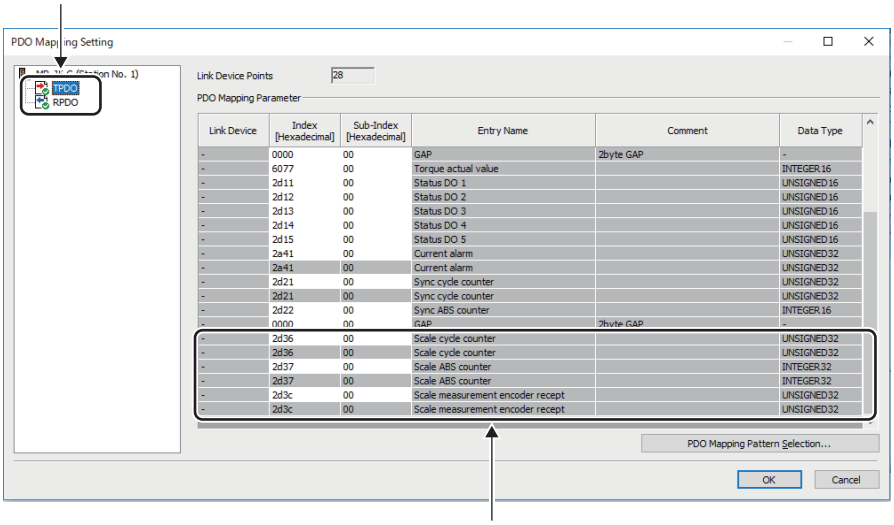
*1 Set the setting that matches with the setting of the synchronous encoder and drive unit side to be connected. When "-1: Automatic Setting (Acquire from Connected Device) (Auto)" is set, the absolute position system setting is acquired from the drive unit side.



*2 The data refresh cycle of the synchronous encoder is the control cycle of the connected real drive axis and the axis control may not be executed by each data refresh cycle when it differs with the real encoder axis setting. Thus, It is recommended that the real encoder axis control cycle is set as the same cycle as the connecting real drive axis.

■PDO mapping setting

Regarding the network configuration setting of GX Works3, set all three objects of the following to the PDO mapping (TxPDO) of the real drive axis 1 (MR-J5(W)-G station address: 192.168.4.1).



- Scale cycle counter (Index: 2d36, subindex: 00)
- Scale ABS counter (Index: 2d37, subindex: 00)
- Scale measurement encoder reception status (Index: 2d3c, subindex: 00)

Executes PDO mapping setting to the first station to use the scale measurement device of the first station as an input of the real encoder axis 2.

Change "RWr Setting" and "RWw Setting" to the required number of points in the PDO mapping setting.

The setting window of TPDO and RPDO can be switched here.
Select TPDO.

Add required objects via drive unit.

■Drive unit side (MR-J5(W)-G) setting

To enable the scale measurement function on the MR-J5(W)-G, set the parameter below.

For details on the parameter and connection method of the encoder, refer to the manual of the drive unit used.

No.	Abbreviation	Name	Overview
PA22.3*1	**PCS	Scale measurement function selection	Select scale measurement function. • 0: Invalid (initial setting) • 1: Use with absolute position detection system • 2: Use with incremental system

*1 Available since MR-J5(W)-G (version A5)

Precautions

The following behavior occurs when PE51 is set to a value other than 0 for the phase ABZ differential output type rotary encoder.

- The Scale cycle counter changes suddenly when phase Z is passed for the first time.
- If PE51 is set to an incorrect encoder resolution, the Scale cycle counter value may become invalid.

■Axis setting

Setting item	Axis setting	
	Real drive axis setting	Virtual encoder axis setting
Axis No.	1	4
Axis type	0: Real drive axis (DriveAxis)	4: Virtual Encoder Axis (VirtualEncoderAxis)
Station address	192.168.3.1	Unnecessary
Encoder Ring Counter Upper Limit Value*1	Unnecessary	0
Encoder Ring Counter Lower Limit Value*1	Unnecessary	0
Absolute Position Control Setting	-1	0: Disable Absolute Position System (ABSDisabled)
Control Cycle	0	0
Object Data Setting_PosActualValue	Unnecessary	[VAR](DWORD)MR_J5_G_RJ_001_ScaleCycleCounter

*1 Set the values to fall within the range of the Scale cycle counter.
When the range of the Scale cycle counter is from 0 to 4294967295, the setting will be valid by setting the encoder ring counter upper limit value and the encoder ring counter lower limit value to the same value.
Setting example: Because the range of the Scale cycle counter is from 0 to 4294967295, set the Encoder Ring Counter Upper Limit Value and Encoder Ring Counter Lower Limit Value to 0.

Virtual drive axis

This axis can generate commands virtually in the motion system. The real drive unit is not used. The available commands/functions are partly different from those of the real axis.

Point

Since the virtual drive axis is specialized for generating the position command and it does not simulate a situation that the drive unit is connected, available functions are restricted. For simulating the operation close to the state when the drive unit is connected, use the axis emulation function for the real drive axis. For details, refer to the following.

☞ Page 1186 AXIS EMULATION

Virtual encoder axis

Generates the current position from the motion system variables. Used as an input axis for the single axis synchronous control.

Parameter setting items

Set the following items to use the virtual encoder axis.

○: Necessary, △: Optional, —: Unnecessary

Setting item		Virtual encoder axis	Reference
Axis No.		○	Page 466 Axis No.
Axis type		○	Page 466 Axis type
Station address		—	—
Absolute position control setting		○	Page 467 Absolute Position Control Setting
Control cycle		○	Page 467 Control Cycle
Object Data Setting	PosActualValue	△	Page 462 Object data settings
Driver Unit Conversion Numerator		○	Page 1130 Driver Unit Conversion Function
Driver Unit Conversion Denominator		○	
Position Command Unit setting		○	Page 490 Units
Velocity Command Unit setting		○

Ring Counter Upper Limit Value		△	
Ring Counter Lower Limit Value		△	
Encoder Ring Counter Upper Limit Value		○	Page 462 Encoder ring counter upper limit value/lower limit value
Encoder Ring Counter Lower Limit Value		○	
Counter Disabling Signal		△	Page 504 Follow Up

Object data settings

Set the following.

Object to be set	Description
PosActualValue	Set the string format data used as the encoder input value.*1 Use "Encoder Input Value (AxisName.Cd.Encoder_InputValue)" as the encoder input value when omitted. Set the encoder input value sequentially by encoder pulse unit. • Only [VAR], [DEV], and [CONST] can be specified for the type. If the setting value is not within the valid range, Out of parameter range (axis) (error code: 1A60H) occurs. • When [VAR] type is set, specify the data type to be (INT), (DINT), (WORD) or (DWORD) data. If the data type is other than the above, Out of parameter range (axis) (error code: 1A60H) occurs. • When [DEV] or [CONST] type is set, specify the data type to be (INT), (DINT), (WORD) or (DWORD). If the data type is not specified or the data type is other than the above, Out of parameter range (axis) (error code: 1A60H) occurs. • When [VAR] type is used, do not specify the local label.

*1 For details on the setting value, refer to the following.
☞ Page 1158 TARGET_REF Structure

Encoder ring counter upper limit value/lower limit value

Sets the upper limit value and lower limit value of the encoder input value.
Set the encoder ring counter lower limit value and encoder ring counter upper limit value in accordance with the lower limit value/upper limit value of the encoder input value. If the range of the encoder input value and "the encoder ring counter lower limit value to the encoder ring counter upper limit value" differ, the encoder input value will not be read correctly.
If the encoder ring counter upper limit value = encoder ring counter lower limit value is set, the encoder input value is processed as the 32-bit counter of "-2147483648 to 2147483647" or as the 16-bit counter of "-32768 to 32767".
If the encoder ring counter lower limit value > the encoder ring counter upper limit value, Out of encoder ring counter setting range (error code: 1B13H) occurs.

Point

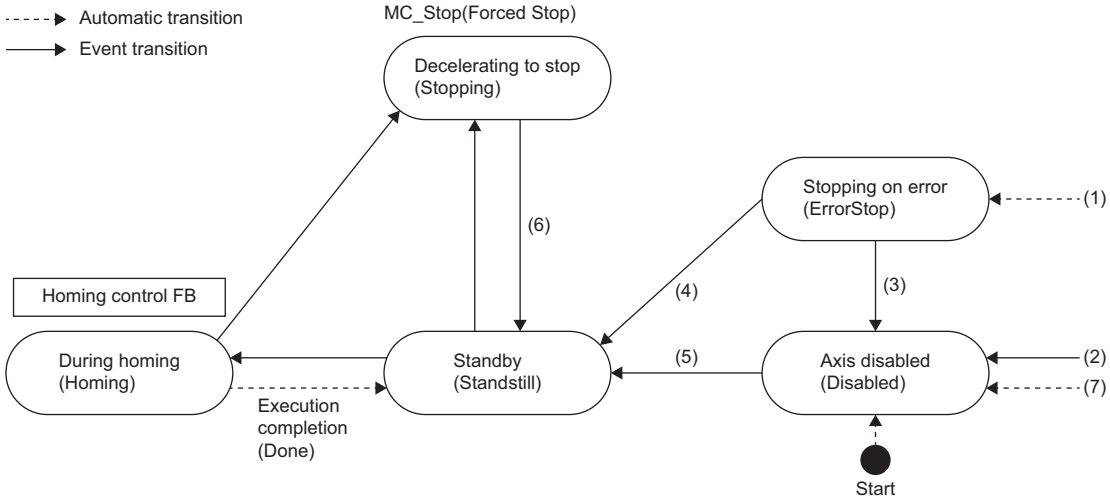
- For the encoder input value, set the cycle counter of "the encoder ring counter lower limit value ≤ the encoder input value ≤ the encoder ring counter upper limit value" as the input value. If the encoder input value is out of the above range, the encoder input value will not be read.
- Set the encoder input value that one operation cycle movement amount meets the following equation. If it does not meet, the actual input movement amount and the movement amount counted by the motion system may not match.

$$\text{One operation cycle movement amount} < \frac{|\text{Encoder ring counter upper limit value} - \text{Encoder ring counter lower limit value} + 1|}{2}$$

- If the encoder input value is out of range of "the encoder ring counter lower limit value to the encoder ring counter upper limit value" when it is connected to the encoder, the encoder current value will restore as below.
  · Absolute position system: Restore to the backup data value
  · Incremental system: Clamp by the encoder ring counter upper limit value/lower limit value

Functions required

The following are the functions required to use the virtual encoder axis.



Function		Reference	Axis type specific detailed information
Axis assignment		Page 466 Axis Assignment	—
Unit		Page 490 Units	—
Compensation function	Driver unit conversion function	Page 1130 Driver Unit Conversion Function	—
Absolute position control		Page 510 Absolute Position Control	—
Operation cycle		Page 522 OPERATION CYCLE	—
State transition	Single axis state transition	Page 463 Single axis state transition	Page 463 State transition
Follow-up (counter enabled/counter disabled)		Page 504 Follow Up	—
Ring counter setting		Page 496 Positioning Range	—
Control change function	Current position change function	Page 1054 Current Position Change Function	Page 458 Control change function
Command filter	Smoothing filter	Page 1133 COMMAND FILTER	—
	Moving Direction Restriction Filter		—

For other functions, refer to each function and check the required object data for the function. If the axis holds the required object data, the function is valid.

State transition

■Single axis state transition

The virtual encoder axis transits to the following state.

No.	State transition description
(1)	Transits from any state when an error of the axis occurs.
(2)	• Transits from any state when Enable (Enable) of MC_Power (Operation Available)/MCv_AllPower (All Axes Operation Available) is FALSE and no error occurs in the axis. • Transits from "4: Standby (Standstill)" when Enable (Enable) of MC_Power (Operation Available)/MCv_AllPower (All Axes Operation Available) is TRUE, Servo ON request (ServoON) is FALSE, and no error occurs in the axis.
(3)	Transits by the status error cancel for the error reset command during the servo OFF state.
(4)	Transits by the status error cancel for the error reset command during the servo ON state.
(5)	After Connection Command (AxisName.Cd.Encoder_Connect) is set to TRUE, the status transits when Enable (Enable) of MC_Power (Operation Available)/MCv_AllPower (All Axes Operation Available) is TRUE, Servo ON request (ServoON) is TRUE, and Operable (Status) of MC_Power (Operation Available) is TRUE.
(6)	Transits when Execution completion (Done) of MC_Stop (Forced Stop) is TRUE and Execution command (Execute) of MC_Stop (Forced Stop) is FALSE.
(7)	Transits from any state other than the "1: Stopping on error (ErrorStop)" status when Connection Command (AxisName.Cd.Encoder_Connect) is FALSE.

Point

- Follow-up is performed in "4: Standby (Standstill)" and "3: During homing (Homing)".
- Follow-up is disabled in "0: Axis disabled (Disabled)", "1: Stopping on error (ErrorStop)", and "2: Decelerating to stop (Stopping)". For the set position when follow-up is disabled, refer to the following.

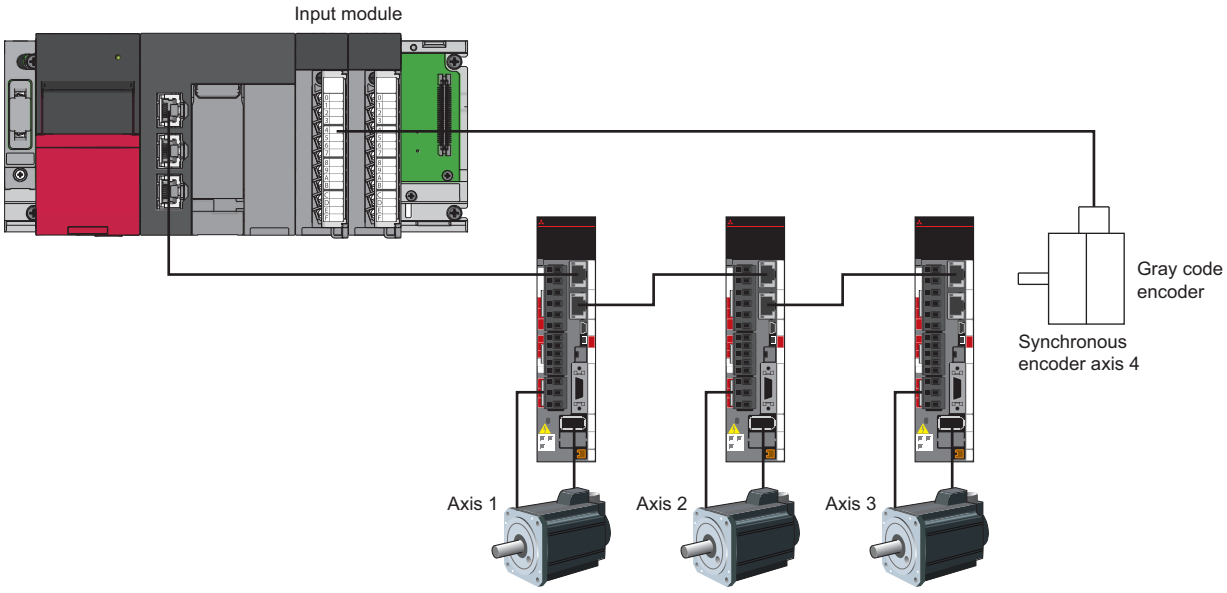
☞ Page 506 Disabling follow up

Control change function

When starting the current position change control unconditionally, use the MC_SetPosition (Current Position Change).

Restriction

The encoder input value will be read by every virtual encoder axis control cycle. When the encoder input value update cycle is slow, the velocity change increases. Use the smoothing filter to smooth the velocity change.



Setting example

The setting example of the virtual encoder axis and the method of use are shown below.

Ex.

When the axis 4 is used as the virtual encoder axis.

(Gray code encoder connected to the input module: The resolution 4096 [pulse/rev] encoder value is used to control.)

■Axis setting

Setting item	Setting value
Axis No.	4
Axis type	4: Virtual Encoder Axis (VirtualEncoderAxis)
Absolute Position Control Setting	0: Disable Absolute Position System (ABSDisabled)
Encoder Ring Counter Upper Limit Value*1	4095
Encoder Ring Counter Lower Limit Value*1	0
Object data_PosActualValue	[DEV](DINT)G11478000

*1 Set the value according to the resolution of the gray code encoder.

■How to use virtual encoder axis

1. Set Connection Command (AxisName.Cd.Encoder_Connect) to TRUE.
2. Check that Current Position Restoration Status (AxisName.Md.PosRestoration_Status) is "2: Restoration Completed in Incremental System (RestoredInIncSystem)" and Connection Status (AxisName.Md.Encoder_Connected) is TRUE.
3. Set Enable (Enable) of MC_Power (Operation Available)/MCv_AllPower (All Axes Operation Available) and Servo ON request (ServoON) to TRUE.
4. Check that Axis Status (AxisName.Md.AxisStatus) is "4: Standby (Standstill)".
5. Read the encoder value of the gray code encoder by program, update the device setup on PosActualValue with object data setting sequentially. (The virtual encoder axis will be controlled based on the change amount of PosActualValue.)

Virtual linked axis

This axis connects FBs of single axis synchronous control. Since the minimum data for FB connection is defined, the processing load is reduced compared to the FB connection using, for example, a virtual drive axis.

How to generate an axis

Set it according to axis assignment. For the axis assignment method, refer to the following.

☞ Page 466 Axis Assignment

Precautions

- Software stroke limit cannot be set in the virtual linked axis. When virtual linked axes are used to connect between each user program of single axis synchronous control, set the software stroke limit in the end axis of connected single axis synchronous control.
- When temporarily generated axis is started, it will take longer than the usual to start the axis because the axis variables are generated in the motion service processing.

23.3 Axis Assignment

Axes are generated/initialized by setting axis settings on the axis setting window in the engineering tool. The axes set on the axis setting window are assigned to the global label as axis variables. For the setting method, refer to Help of the engineering tool.

Operation of this function for each system status

○: Available, ×: Not available

System status	Operation availability
STOP	○
RUN	○
Moderate error	○
Major error	×

Setting item

The items set to the axis type are shown below.

○: Necessary, —: Unnecessary

Axis type	Setting item					
	Axis name	Axis No.	Axis type	Station address	Absolute position control setting	Control cycle
Real drive axis	○	○	○	○	○	○
Real encoder axis	○	○	○	○	○	○
Virtual drive axis	○	○	○	—	○	○
Virtual encoder axis	○	○	○	—	○	○
Virtual linked axis	○	○	○	—	○	○

■Axis Name

Set an arbitrarily axis name of the applicable axes within 127 characters.

An instance is generated as the set axis name.

■Axis No.

It is an identifier on the motion system control.

If the same No. is set in the multiple axes, Axis No. setting duplication error (error code: 1AEBH) will occur.

Axis setting	Axis No.
User specification	1 to 10000
Virtual linked axis generated automatically	20001 to 30000

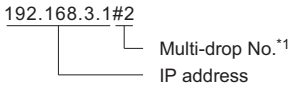
■Axis type

Specify an axis type of the axis.

Axis type	Setting value
Real drive axis	0: DriveAxis
Real encoder axis	2: EncoderAxis
Virtual drive axis	3: VirtualDriveAxis
Virtual encoder axis	4: VirtualEncoderAxis
Virtual linked axis	5: VirtualLinkAxis

The data type that an axis variable can take differs depending on the axis type.

For details on data types of each axis type, refer to the following.



☞ Page 445 Data type

■Station address

Specify the station address (IP address) of the target device to connect a network device as a real axis. Also, specify the multidrop No. for connecting a device which can control multiple axes with one device (multiple axes device).

Ex.

When specifying the C-axis of a multiple axes device (MR-J5(W)-G)

*1 The multidrop No. is specified as "# + No. (decimal)". When omitted, it is regarded as "#0".
· #0: A-axis
· #1: B-axis
· #2: C-axis

When the station address of a device that cannot be used on real axes is specified, SLMP communication error (error code: 1A42H) or Station address setting incorrect (error code: 1AEDH) occurs. (Example: When a station address of an I/O module is specified)

Only station addresses connected to the port for CC-Link IE TSN can be specified.

These settings are unnecessary to the virtual axis.

For the station address, specify the same format as "Target modification (character string starts with @)" of TARGET_REF structure. For details on the TARGET_REF structure, refer to the following.

☞ Page 1158 TARGET_REF Structure

Even though the station address has not been set ("") in the real axis, setting Axis Emulation Enabled (AxisName.PrConst.SlaveEmulate_Enable) to TRUE allows it to be used as the axis emulate function. If axis emulate function is not used, Station address setting incorrect (error code: 1AEDH) occurs and the axis will not be ready for operation.

■Absolute Position Control Setting

Specify whether applicable axes are used as the absolute position system. For details, refer to the following.

☞ Page 510 Absolute Position Control

■Control Cycle

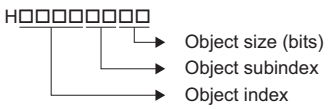
Specify which operation cycle is used for the applicable axis to control. For details, refer to the following.

☞ Page 522 OPERATION CYCLE

Relevant variables

AxisName in the following table indicates the instance name of the structure type for each axis type.

- AXIS_REAL: Real drive axis
- AXIS_ENCODER: Real encoder axis
- AXIS_VIRTUAL: Virtual drive axis
- AXIS_VIRTUAL_ENCODER: Virtual encoder axis
- AXIS_VIRTUAL_LINK: Virtual linked axis



Axis information (AxisName.AxisRef.)

Variable/structure name	Name	Details
AxisNo	Axis No.	Sets the axis No. • 0: Not set • 1 to 10000: Set axis No.

Axis parameter constant (AxisName.PrConst.)

Variable/structure name	Name	Details
AxisType	Axis Type Setting	Sets the axis type. • 0: Real Drive Axis (DriveAxis) • 2: Real Encoder Axis (EncoderAxis) • 3: Virtual Drive Axis (VirtualDriveAxis) • 4: Virtual Encoder Axis (VirtualEncoderAxis) • 5: Virtual Linked Axis (VirtualLinkAxis)
AddressOfStation	Station Address Setting	Sets network address of the device station with a character string.
PosRestoration_AbsPosEnable	Absolute Position Control Setting	Sets the absolute position control setting. • 0: Disable Absolute Position System (ABSDisabled) • 1: Enable Absolute Position System (Enabled) • -1: Automatic Setting (Acquire from Connected Device) (Auto)
OperationCycle	Control Cycle Setting	Sets the control operation cycle. For details, refer to the following. ☞ Page 522 OPERATION CYCLE
SlaveObject	Object Data	Sets the object of the device station.

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
AxisName	Axis Name	Displays the axis name.
Io_PosActualValue	Object Data_PosActualValue	Displays the value of object data Position actual value (6064H).
Io_PosEncoderResolution	Object Data_PosEncoderResolution	Displays the value of object data Position encoder resolution (608FH).
Io_Statusword	Object Data_Statusword	Displays the value of object data Statusword (6041H).
Io_TargetPos	Object Data_TargetPos	Displays the value of object data Target position (607AH).
Drive_RPDO[1..64]	RPDO (the device to the motion system) mapping	Indicates the object index specified to the nth place in the RPDO/TPDO mapping settings of the network parameter.  • The object size displays 1 byte, 2 bytes, 4 bytes, and 8 bytes in bits. • When the size of the nth object is 1 byte, a padding object is inserted in the nth+1 place.
Drive_TPDO[1..64]	TPDO (the motion system to the device) mapping	

Object data settings

In the motion system, the data that sends/receives information to/from the connected device in the motion operation processing is called object data.

With object data settings, the motion system can be customized to adjust to the device station by setting the data related to the device station to the object data.

For one set of object data, set as follows.

Setting item	Setting value
Each member of Object Data (AxisName.PrConst.SlaveObject)	Specifies the target data to set. The data that can be used differs depending on the axis type. Refer to the following. ☞ Page 449 Axis Type For details on the format to specify the data, refer to the following. ☞ Page 1158 TARGET_REF Structure * For whether or not mapping to cyclic data is required when using [OBJ], refer to the following. ☞ Page 472 Object data list * For whether or not the target modification must be used, refer to the following. ☞ Page 1163 @Target modification

If unavailable data is set, Mapping communication error (error code: 1AC7H) will occur at the axis variable initialization.

There are object data whose settings are necessary depending on the axis type. A valid setting value other than "no setting" must be set in the applicable object data. (If the setting is illegal, "Object Data Setting Incorrect (error code: 1AEEH)" will occur at the axis variable initialization.)

For object data whose settings are necessary, refer to the following.

☞ Page 472 Object data list

When "no setting" is set in the object data setting, motion system functions that need the applicable object data cannot be used. For details, refer to the following.

☞ Page 477 Motion system function and object data

Data and information of the setting location are sent/received based on the data type of each object data in the motion operation processing.

Access	Data size	Description of the motion operation processing
R: Device station → Motion system	(Object data) < (Setting location data)	Converts the setting location data to data size of object data and imports it. Exceeded upper bit information is discarded.
	(Setting location data) ≤ (Object data)	Converts the setting location data to data type of object data and imports it.
W: Motion system → Device station	(Setting location data) < (Object data)	Stores an object data value as it is to the setting location data. After it is stored, shorted upper bit does not change before and after refreshing.
	(Object data) ≤ (Setting location data)	Converts a value to data size of the setting location data and stores it. Exceeded upper bit information is discarded.

PDO mapping setting

Data (object) that is sent/received between the controller and the device station in cyclic transmission (PDO communication) must be mapped in advance to control each function in the real drive axis.

For details on the PDO mapping setting, refer to the following.

☞ Page 165 PDO mapping setting

Mapping is required for some objects to be connected as real drive axes in the motion system. The following objects must be mapped. (If the objects are not mapped, Necessary object data unset (error code: 1AF7H) will occur.)

Mapping	Required object data
Output (RPDO)	Controlword (6040H)
	Target position (607AH)
	Modes of operation (6060H)
Input (TPDO)	Statusword (6041H)
	Position actual value (6064H)
	Modes of operation display (6061H)

Setting procedure

This section describes the procedure to newly set a real drive axis by using the engineering tool.

1. Add the device station to the network configuration setting, and set IP address and PDO map information.
2. Select adding axis in the axis setting of the motion system, and set axis information.
3. Double-click the set axis and set the axis parameters.
4. Select the object data setting, and assign object data.
5. Write the parameters in the motion system.

Memory usage

Axis variables use the following memory.

Name	Setting method
Label Memory	Set in Label Area Capacity of the engineering tool.
Add-on Axis System Memory	AddonSystem.PrConst.MT_Axis.RamSizeMax

The system memory usage differs depending on the axis type. Specify the memory capacity of the system according to the axis type and the number of axes.
Memory capacity per one axis for each axis type is shown below

Axis type	Memory usage (K bytes/axis)
Real drive axis	160
Real encoder axis	40
Virtual drive axis	60
Virtual encoder axis	40
Virtual linked axis	40

Point

Regarding the system memory to be used, memory is secured at the following timing:

- Secure memory: At axis variable initialization

When there is no sufficient free space, Axis data memory size over (error code: 1AC5H) occurs, and the relevant axis is not generated. Check the memory capacity and restart the system.
Check the memory capacity of the following add-on library as needed.

- MotionEngine
- NetworkDriver_CCIETSN*1
- ServoDriver_CANopen*1
- SignalIO*2
- ExternalSignal*2

*1 For using real drive axis
*2 For using external signal

Object data list

The following shows attributes of object data.

Attribute	Description
PDO mapping	Indicates whether the mapping to cyclic transmission is enabled or not for the object when [OBJ] is specified. • No: Mapping to TxPDO and RxPDO is not required. • TxPDO: Mapping to TxPDO is enabled. • RxPDO: Mapping to RxPDO is enabled. Shows the relationship of access between the motion system and the device station when the axis type is a real drive axis or a real encoder axis. • No: The motion system will access to the data unperiodically even after mapping. • TxPDO: Mapping enables the motion system to read the data from the device station in fixed-cycle. • RxPDO: Mapping enables the motion system to write the data to the device station in fixed-cycle.
Default	Indicates the default value of the object data for the real drive axis.

The object data lists are shown below.

Whether each axis type can be set or not is as shown below depending on the object data setting and the PDO mapping setting (real drive axis only).

○: Setting possible··· It can be set in the object data setting of the engineering tool. For object data whose PDO mapping attribute is TxPDO or RxPDO in the real drive axis, be sure to set the setting value of the object data setting to the PDO mapping setting. When the setting is valid, the axis holds the applicable object data.

×: Setting not possible··· It cannot be set in the object data setting of the engineering tool. The axis does not hold the applicable object data.

—: Unnecessary··· It cannot be set in the object data setting of the engineering tool. However, since it is emulated in the motion system, the axis holds the applicable object data.

Object data name	PDO mapping	Default	Data sent from motion system ○: Applicable —: Not applicable	Description	Whether each axis type can be set				
					Real drive axis	Real encoder axis*1	Virtual drive axis	Virtual encoder axis	Virtual linked axis
Supported drive modes	No	65020020	○	Acquires the control mode supported by the drive unit.	○	×	×	×	×

*1 For the real encoder axis object data names, refer to the following.
☞ Page 455 Real encoder axis

*2 The names in parentheses are the object names associated with Index.

Point

- If a value larger than DataType is set for the object data, the upper bits of DataType or higher are rounded off and converted to the same size as DataType.
- When the data type [OBJ] is set, an object whose DataType is INTEGER 8, 16, or 32 or UNSIGNED 8, 16, or 32 can be set. If an object whose DataType is other than the above is specified, intended data cannot be sent or received and the function using the object data does not operate normally.
  If a size other than 8 bits, 16 bits, or 32 bits is set in the DataType part of the setting value, Object Data Setting Incorrect (error code: 1AEEH) will occur.

Motion system function and object data

If no object data is registered in the axis, there will be errors and restrictions in the following functions.

Instruction/function	Required object data	Reference
MC_MoveVelocity (Speed Control)	TargetVelocity	Page 715 Velocity Control
MC_TorqueControl (Torque Control)	TargetTorque	Page 726 Torque Control
Torque limit function	PositiveTorqueLimitValue NegativeTorqueLimitValue	Page 1124 Torque Limit
MC_Home (Homing)	HomeOffset	Page 620 Driver homing method

Precautions

- The motion system does not check the command limit, issue an emergency stop command, or reset an error for the MR-J5(W)-G whose axis is not assigned. Provide safety measures in the user program or on the MR-J5(W)-G side.
- In the graph function of MR Configurator2, if a drive unit whose axis is not assigned is included as the measurement target axis, specify a drive unit whose axis has been assigned as the trigger axis. Also, create a network label as shown below and add a fixed scan execution program (Cycle: Operation cycle).

Measurement target drive unit	Object used	Network label name example
Drive unit specified as the trigger axis	Status DO 4	MR_J5_G_001_StatusDO4
Drive unit in which axes other than the trigger axis are not assigned	Control DI 4	MR_J5_G_002_ControlDI4 MR_J5_G_003_ControlDI4
Drive unit in which axes other than the trigger axis are assigned	None	

- If the drive unit whose axis is not assigned is specified as the trigger axis or the following program is not added, waveform data measurement will not be completed even if the trigger condition is satisfied.

ST program
// MR Configurator2 multi-axis graph measurement MR_J5_G_002_ControlDI4.c := MR_J5_G_001_StatusDO4.c; MR_J5_G_003_ControlDI4.c := MR_J5_G_001_StatusDO4.c;

Relevant add-on

The following add-ons are required to use this function.

- Axis

System memory capacity

For details, refer to the following.

☞ Page 471 Memory usage

23.4 Axes Group

Axes group is used for multiple axes control such as linear interpolation control and circular interpolation control.
The maximum setting number of axes groups depends on the memory. If an axes group cannot be set for memory shortage, Maximum number of registrations for axes group over (error code: 1AC8H) occurs. The maximum number of configuration axes of the axes group to be registered is 16.

Operation of this function for each system status

○: Available, ×: Not available

System status	Operation availability
STOP	○*1
RUN	○
Moderate error	○*2
Major error	×

*1 Only monitor is available. When the axes group status is Standby, Axes Group Disabled occurs.
*2 When a necessary add-on has stopped due to an Add-on Library Load Error or Insufficient Add-on System Memory (RAM), operation is not possible.

Relevant variables

Axes group information (AxesGroupName.AxesGroupRef.)

Variable/structure name	Name	Details
GroupNo	Axes Group No.	Sets axes group No. in the motion system. • 0: Not set • 1 and later: Setting axes group No.

Axes group information (AxesGroupName.PrConst.)

Variable/structure name	Name	Details
AxesGroupType	Axes group type	Sets the axes group type.

Axes group parameter (AxesGroupName.Pr.)

Variable/structure name	Name	Details
Axis[1..16]	Configuration Axis	Sets Axis No. (AxisNo) of Axis Information (AxisName.AxisRef) which configures the axes group.

Axes group monitor data (AxesGroupName.Md.)

Variable/structure name	Name	Details
GroupStatus	Axes Group Status	Displays the current axes group status. • -1: Axes group variable not initialized/axes group parameter error (Invalid) • 0: Axes group disabled (GroupDisabled) • 1: Stopping on error (GroupErrorStop) • 2: Decelerating to stop (GroupStopping) • 4: Standby (GroupStandby) • 5: Operating (GroupMoving)
GroupName	Axes Group Name	Stores the axes group name.
Axis[1..16]	Configuration Axis	Stores Axis No. (AxisNo) of Axis Information (AxisName.AxisRef) which configures the axes group.

Relevant FBs

For details on motion control FBs, refer to the following.

📖MELSEC MX Controller MX-R Model Programming Manual

Motion control FB	Name	Description
MC_GroupEnable	Axes Group Enabled	Transits the specified axes group status from "0: Axes group disabled (GroupDisabled)" to "4: Standby (GroupStandby)".
MC_GroupDisable	Axes Group Disabled	Transits the specified axes group status to "0: Axes group disabled (GroupDisabled)".

Settings required for axes group

Set the following parameters using the engineering tool to set axes groups.

For setting methods of axes group, refer to the following.

☞ Page 487 Axes Group Assignment

Item	Description
Axes group No.	Sets axes group No. of the motion system.
Axes group name	Sets an arbitrary axes group name.
Configuration axis	Sets Axis No. (AxisNo) of Axis Information (AxisName.AxisRef) which configures the axes group.

Axes group variables

Axes group variables are generated by adding the axes group setting in the engineering tool. A generated axes group is assigned to the global label as an axes group variable.

Axes group is defined as an axes group variable configured with monitor information such as parameter information, the current position, and the status.

Axes group variable name (default)

The following names are assigned based on the axes group No. They can be changed to an arbitrary name. For details, refer to the following.

☞ Page 487 Axes Group Assignment

Set axes group No.	Engineering tool default axis name
1	AxesGroup001
2	AxesGroup002
⋮	⋮

Data type

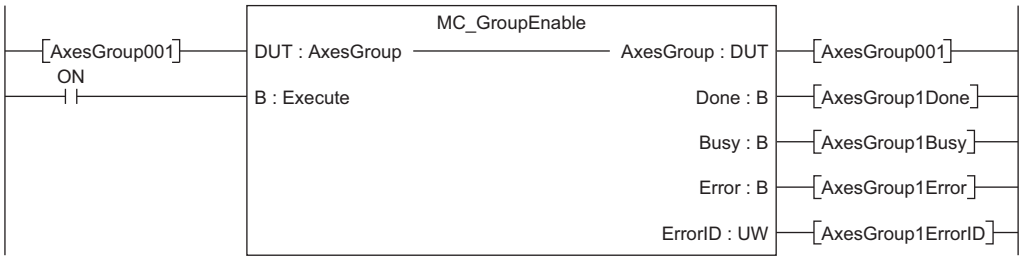
Data types of axes groups are expressed using the AXES_GROUP type. Data types of axes groups have the following members.

Member name	Data type	Description
AxesGroupRef	AXES_GROUP_REF	A data structure for input/output of motion control FBs.
PrConst	AXES_GROUP_PRM_CONST	Stores parameter data (constant) of the axes group. Opens the default value at axes group variable generation. Re-importing to the control data is not executed after axes group variables initialization.
Pr	AXES_GROUP_PRM	Stores parameter data of the axes group. Opens the default value at axes group variable generation. The timing to import to the control changes depending on the parameter.
Md	AXES_GROUP_MONI	Stores monitor data of the axes group. Executes refresh in the fixed cycle for each monitor data.
Cd	AXES_GROUP_CMD	Stores command data for axes group control. Acquires the latest value every control operation cycle and uses it for the control.

Axes group variable initialization timing

Axes group variables are initialized at the following timings.

Timing	Processing
At power supply When the controller is reset	Refers to the global label data, and initializes all set axes group variables.
When PLC READY (MotionSystem.Cd.SequenceReady) is turned on	■Uninitialized axis group Refers to the global label data and initializes all axes group variables. ■Initialized axes group Refers to the global label data for the axes group parameter data and imports it again. However, the configuration axis is not imported again. When the parameter error occurs at importing, the axes group is not deleted. At this time, built-in motion ready [X20] does not turn on. For the label initialization processing when PLC READY (MotionSystem.Cd.SequenceReady) is turned on, refer to the following. ☞ Page 426 DEVICE/LABEL INITIAL VALUE SETTINGS
At online program change	Refers to the global label data and initializes the axes group variables that have not yet been initialized.



How to specify in a user program

When specifying the axes group by the motion control FB, set the AXES_GROUP_REF type member (AxesGroupName.AxesGroupRef) of each axes group variable to the I/O variables whose data type is "AXES_GROUP_REF".

Ex.

When executing the MC_GroupEnable (Axes Group Enabled) with the following settings

- Axes group number: 1
- Axes group name: AxesGroup0001

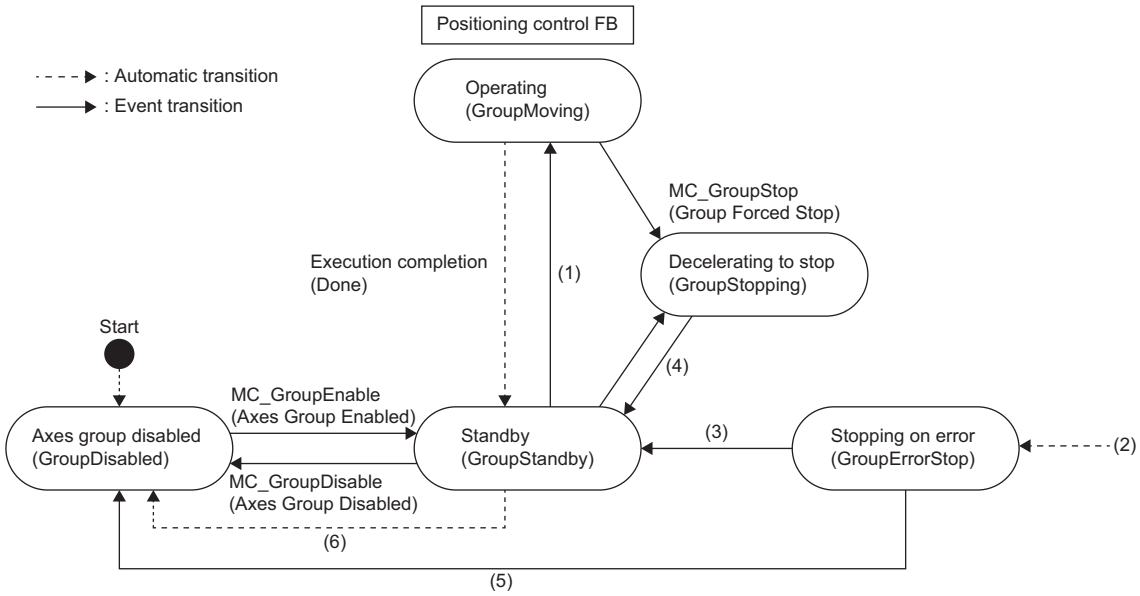
Axes group status

When an axes group is used in the motion FB, Axes Group Status (AxesGroupName.Md.GroupStatus) must be set to "4: Standby (GroupStandby)" by executing MC_GroupEnable (Axes Group Enabled) to the axes group. The axes group can be started in the motion FB when Axes Group Status (AxesGroupName.Md.GroupStatus) is "4: Standby (GroupStandby)" and Axis Status (AxisName.Md.AxisStatus) of all configuration axes is "4: Standby (Standstill)".

Axes group state transition

The following shows status that an axes group can enter.

The current status can be checked with Axes Group Status (AxesGroupName.Md.GroupStatus).



When the axes group changes to "4: Standby (GroupStandby)", Using Axes Group (AxisName.Md.UseInGroup) of the configuration axis becomes TRUE.

When the motion FB is executed for the axis (the axis of which Using Axes Group (AxisName.Md.UseInGroup) is TRUE) used in the axes group, Start not possible (error code: 1AFCH) occurs. Disable the axes group by MC_GroupDisable (Axes Group Disabled).

Status	Description
-1: Axes group variable not initialized/axes group parameter error (Invalid)	Axes group is disabled because the axes group variables are not initialized (such as a parameter error occurrence at initialization).

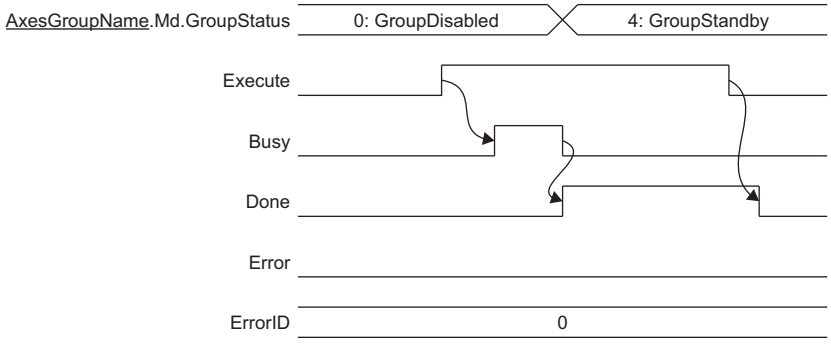
Status	Description
0: Axes group disabled (GroupDisabled)	Axes group is disabled. Motion control FBs cannot be executed in this status. The axis which is being controlled will be stopped immediately to transit to this state.
1: Stopping on error (GroupErrorStop)	Axes group is in the deceleration stop or the stop status by an error occurrence. When Axis Status (AxisName.Md.AxisStatus) is set to "1: Stopping on error (ErrorStop)" in any of the configuration axes, the axes group also enters this status.
2: Decelerating to stop (GroupStopping)	The deceleration stop is executed by MC_GroupStop (Group Forced Stop). After the axis stop is completed, this status will be maintained until the Execution command (Execute) of MC_GroupStop (Group Forced Stop) becomes FALSE. Motion control FBs cannot be executed in this status.
4: Standby (GroupStandby)	Axes group is enabled and stand-by. (Not depending on the servo ON/OFF status of the configuration axis.)
5: Operating (GroupMoving)	The positioning control FB is executed in an axes group. When transiting into this status, Axis Status (AxisName.Md.AxisStatus) of all configuration axes turns to "7: During synchronous operation (SynchronizedMotion)".

The status transits as shown below according to the start of the motion control FB.

No.	State transition description
(1)	All group motion FBs
(2)	• Transits when an error caused by an axes group occurs in the status other than "0: Axes group disabled (GroupDisabled)". • Transits when an error caused by a configuration axis occurs in the status other than "0: Axes group disabled (GroupDisabled)".
(3)	Transits when status error is cleared by axes group error reset. For clearing errors, refer to the following. ☞ Page 1751 Error clear
(4)	Transits when Execution completion (Done) of MC_GroupStop (Group Forced Stop) is TRUE and Execution command (Execute) of MC_GroupStop (Group Forced Stop) is FALSE.
(5)	Transits when the axes group is disabled at executing MC_GroupDisable (Axes Group Disabled) or clearing the status error by axes group error reset.
(6)	Transits when a stop of program execution is completed by a change from the RUN status → STOP status.

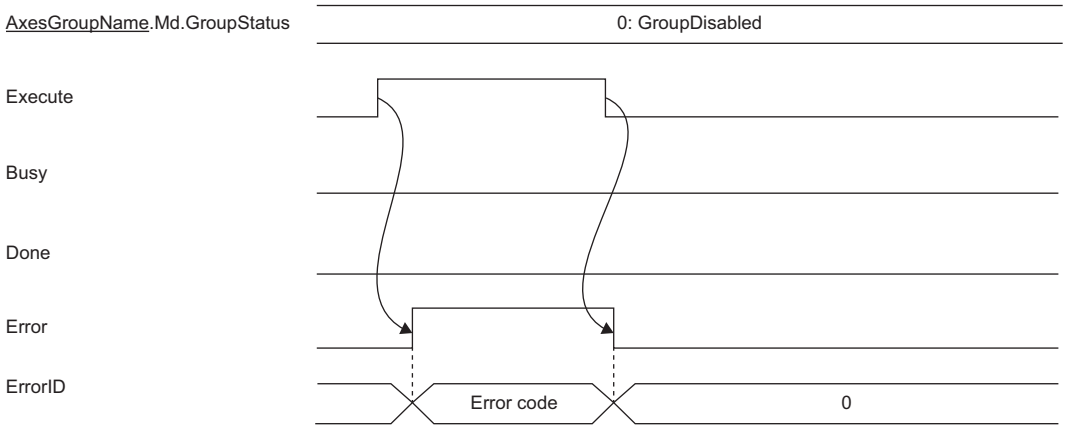
Axes group enabled

This section describes enabling an axes group.



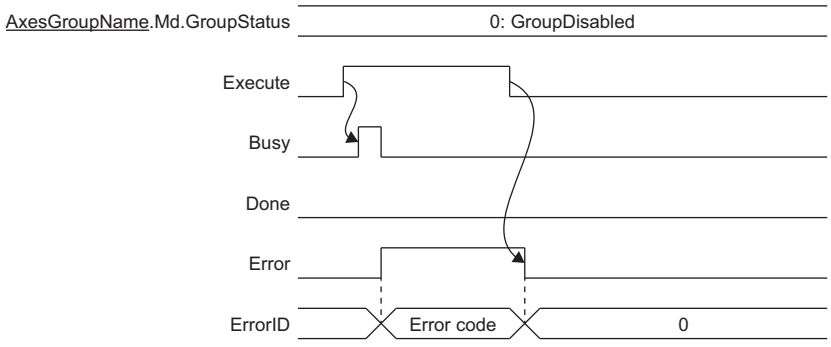
Control details

Axes Group Status (AxesGroupName.Md.GroupStatus) can be changed to "4: Standby (GroupStandby)" by specifying Axes Group Information (AxesGroup).



- The axes group can start the motion FB only when Axes Group Status (AxesGroupName.Md.GroupStatus) is "4: Standby (GroupStandby)".
- MC_GroupEnable (Axes Group Enabled) can be executed only when Axis Status (AxisName.Md.AxisStatus) of all configuration axes is "4: Standby (Standstill)" or "0: Axis disabled (Disabled)".
- When Axes Group Status (AxesGroupName.Md.GroupStatus) changes to "4: Standby (GroupStandby)", Using Axes Group (AxisName.Md.UseInGroup) of the configuration axis becomes TRUE.
- When executing MC_GroupEnable (Axes Group Enabled) with another axes group specified that includes a configuration axis for which Using Axes Group (AxisName.Md.UseInGroup) is TRUE, Axes group configuration axis is in use (error code: 1BB8H) occurs.
- If the error occurs in any of the configuration axes, Axes Group Status (AxesGroupName.Md.GroupStatus) changes to "1: Stopping on error (GroupErrorStop)".
- When MC_GroupEnable (Axes Group Enabled) is executed for an axes group that has already been enabled, Execution completion (Done) becomes TRUE and the execution ends.

■Timing chart



- When the operation is normally completed

- When the I/O variables are abnormal

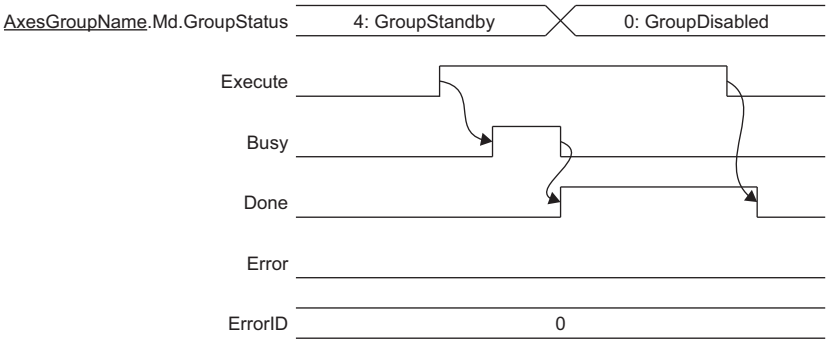
- When the operation is completed with an error

Precautions

Before executing MC_GroupEnable (Axes Group Enabled), ensure that the axes group number (AxesGroupNo) of AXIS_REF structure is set in advance.

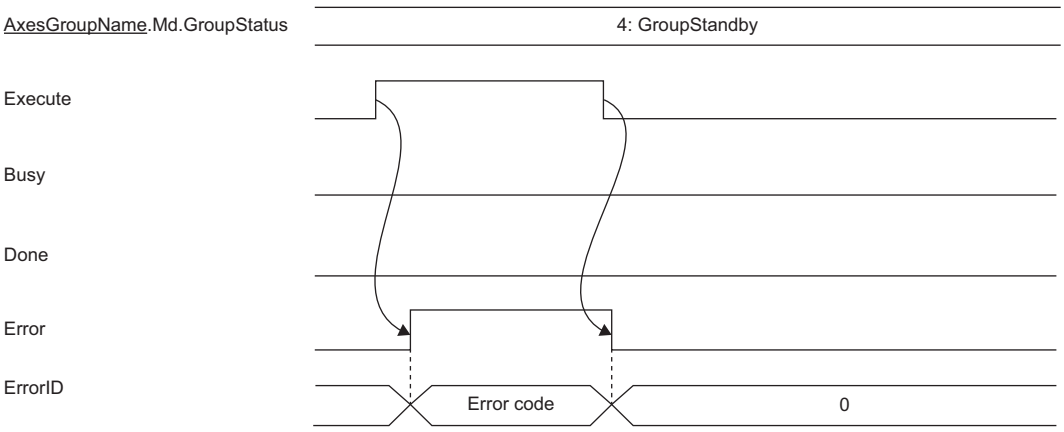
Axes group disabled

This section describes disabling an axes group.



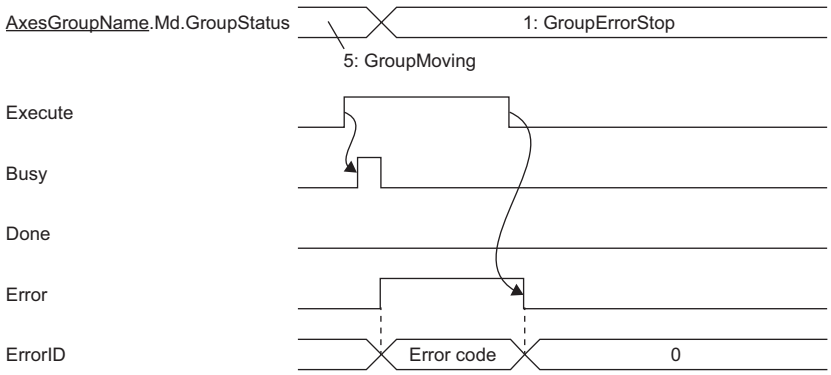
Control details

Axes Group Status (AxesGroupName.Md.GroupStatus) can be changed to "0: Axes group disabled (GroupDisabled)" by specifying Axes Group Information (AxesGroup).



- An axes group cannot execute the motion FB when Axes Group Status (AxesGroupName.Md.GroupStatus) is "0: Axes group disabled (GroupDisabled)".
- MC_GroupDisable (Axes Group Disabled) can only be executed when Axes Group Status (AxesGroupName.Md.GroupStatus) is "4: Standby (GroupStandby)" or "1: Stopping on error (GroupErrorStop)". When executing this FB while Axes Group Status is "1: Stopping on error (GroupErrorStop)" and the axes group is in operation, the axes group status transits to "0: Axes group disabled (GroupDisabled)" after the stop completes. When this FB is executed while Axes Group Status (AxesGroupName.Md.GroupStatus) is other than "4: Standby (GroupStandby)" or "1: Stopping on error (GroupErrorStop)", Axes group status incorrect (when axes group is disabled) (error code: 1AEFH) occurs and the positioning control FB stops. For details on stop processing, refer to the following.
  ☞ Page 578 Stop
- When Axes Group Status (AxesGroupName.Md.GroupStatus) changes to "0: Axes group disabled (GroupDisabled)", Using Axes Group (AxisName.Md.UseInGroup) of the configuration axis becomes FALSE.
- When MC_GroupDisable (Axes Group Disabled) is executed for an axes group that has already been disabled, Execution completion (Done) becomes TRUE and the execution ends.

■Timing chart



- When the operation is normally completed

- When the I/O variables are abnormal

- When the operation is completed with an error (Example where Axes Group Disabled is executed when Axes Group Status is "5: Operating (GroupMoving)")

Precautions

Before executing MC_GroupDisable (Axes Group Disabled), ensure that the axes group number (AxesGroupNo) of AXIS_REF structure is set in advance.

Precautions

If the parameter error occurs at axes group variable initialization, Out of parameter range (axes group) (error code: 1A61H) occurs. In this case, Axes Group Status (AxesGroupName.Md.GroupStatus) changes to "-1: Axes group variable not initialized/axes group parameter error (Invalid)". Refreshing of monitor data and other items is not executed for axes groups whose status is " -1: Axes group variable not initialized/axes group parameter error (Invalid)".
Deleting an axis or axes group variable by writing to the controller (including online program change) causes an Invalid write to the controller (error code: 3408H). Then, the motor will immediately stop due to the setting. Note that immediate stop may damage the machine.

Relevant add-ons

The following add-ons are required to use this function.

- Axis
- MotionEngine
- MotionControl_General

System memory capacity

■Backup RAM Usage

Backup RAM is not used.

23.5 Axes Group Assignment

Axes groups can be set in the engineering tool. For the setting method, refer to Help of the engineering tool.
Based on parameter settings of the axes group, the instance of the axes group is initialized when the controller is powered on, the controller is reset, or PLC READY (MotionSystem.Cd.SequenceReady) is turned on.

Operation of this function for each system status

○: Available, ×: Not available

System status	Operation availability
STOP	○
RUN	○
Moderate error	○
Major error	×

Relevant variables

Axes group monitor data (AxesGroupName.AxesGroupRef.)

Variable/structure name	Name	Details
GroupNo	Axes Group No.	Sets the axes group No. • 0: Not set • 1 to 10000: Set axes group No.

Axes group monitor data (AxesGroupName.Pr.)

Variable/structure name	Name	Details
Axis[1..16]	Configuration Axis	Sets Axis No. (AxisNo) of Axis Information (AxisName.AxisRef) which configures the axes group.

Axes group monitor data (AxesGroupName.Md.)

Variable/structure name	Name	Details
NumberOfAxes	Number of Configuration Axes	Indicates the number of configuration axes of the axes group.
GroupName	Axes Group Name	Stores the axes group name.
Axis[1..16]	Configuration Axis	Stores Axis No. (AxisNo) of Axis Information (AxisName.AxisRef) which configures the axes group.

Setting with engineering tool

In the axes group setting window of the engineering tool, an axes group can be generated/initialized by setting the axes group setting as a parameter. The axes group set in the axes group setting window is assigned to the global label data as an axes group variable.

Setting items

■Axes group No.

It is an identifier on the motion system control.

If the same No. is set in the multiple axes groups, Axes group No. setting duplication error (error code: 1AC1H) occurs.

The axes group whose axes group No. is "0" is regarded as an unset axes group, and it cannot be used for control.

Item	Setting range
Axes group No.	1 to 10000

■Axes group name

Set an axes group name of the applicable axes group arbitrarily with up to 127 characters.

An instance is generated as a set axes group name.

■Configuration axis

Set configuration axes of an applicable axes group with Configuration Axis (AxesGroupName.Pr.Axis[1..16]).

Set the AxisName.AxesRef structure of the axis variable for the configuration axes.

Set the configuration axes of the maximum 16 axes in the left-justified format from the configuration axis 1.

No axis (error code: 1AF1H) and Axes group configuration axis operation cycle incorrect (error code: 1AC2H) occur for the following cases.

- When there is no configuration axis
- When the operation cycles of the configuration axes are mismatched.

■Axes group type

Specify the axes group type.

Axes group type	Setting value
Normal	0: Standard

The data type that an axis variable can take differs depending on the axes group type.

For details on data types of each axes group type, refer to the following.

☞ Page 478 Axes Group

Setting procedures with the engineering tool

The following shows how to create an axes group with the engineering tool.

1. Create an axis, and set the axis name. (A variable instance of the AXIS_* type is generated.)

Navigation window ⇨ [Motion Setting (CPU Built-in)] ⇨ [Axis] ⇨ Right-click ⇨ [Add New Data]

2. Create an axes group, and set the axes group No. and the axes group name. (A variable instance of the AXES_GROUP type is generated.)

Navigation window ⇨ [Motion Setting (CPU Built-in)] ⇨ [Axes Group] ⇨ Right-click ⇨ [Add New Data]

3. Add an axis to the configuration axes of the axes group.

[Axes group setting]

Precautions

Relevant add-on

The following add-ons are required to use this function.

- Axis

System memory capacity

Axes group variables use the following memory.

Name	Setting method
Label Memory	Set in Label Area Capacity of the engineering tool.
Add-on Axis System Memory	AddonSystem.PrConst.MT_Addon_Axis.RamSizeMax

The system memory usage for the axes group is 60K bytes per axes group.

Point

Regarding the system memory to be used, memory is secured at the following timing:

- Secure memory: At axes group variable initialization

When there is no sufficient free space, Maximum number of registrations for axes group over (error code: 1AC8H) occurs, and the relevant axes group is not generated. Check the memory capacity and restart the system.

24 AXIS MANAGEMENT FUNCTIONS

24.1 Units

The position command unit and the velocity command unit used in the motion control can be set in the "unit setting". Since the unit can be specified freely depending on the control target, intuitive programming and monitoring are available.

Relevant variables

Axis parameter (AxisName.Pr.)

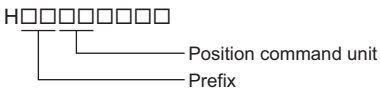
Variable/structure name	Name	Details
Unit_Position	Position Command Unit	Sets the position command unit to be used in the motion control. ☞ Page 491 Position command unit (AxisName(AxesGroupName).Pr.Unit_Position)
Unit_Velocity	Velocity Command Unit	Sets the velocity command unit to be used in the motion control. ☞ Page 492 Velocity command unit (AxisName(AxesGroupName).Pr.Unit_Velocity)
Unit_PositionString	Position Command Unit String	Sets the command unit to be used in the motion control in a character string. It is used when the position unit is set to HFF (an arbitrary unit character string).

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
Unit_PositionDisplay	Position Command Unit Display	Outputs the position command unit that is being controlled in a character string.
Unit_VelocityDisplay	Velocity Command Unit Display	Outputs the velocity command unit that is being controlled in a character string.

Axes group parameter (AxesGroupName.Pr.)

Variable/structure name	Name	Details
Unit_Position	Position Command Unit	Sets the position command unit to be used in the motion control. ☞ Page 491 Position command unit (AxisName(AxesGroupName).Pr.Unit_Position)
Unit_Velocity	Velocity Command Unit	Sets the velocity command unit to be used in the motion control. ☞ Page 492 Velocity command unit (AxisName(AxesGroupName).Pr.Unit_Velocity)
Unit_PositionString	Position Command Unit String	Sets the command unit to be used in the motion control in a character string. It is used when the position unit is set to HFF (an arbitrary unit character string).



Axes group monitor data (AxesGroupName.Md.)

Variable/structure name	Name	Details
Unit_PositionDisplay	Position Command Unit Display	Outputs the position command unit that is being controlled in a character string.
Unit_VelocityDisplay	Velocity Command Unit Display	Outputs the velocity command unit that is being controlled in a character string.

Setting methods

The Position Command Unit and the Velocity Command Unit setting method is shown below.

Position command unit (AxisName(AxesGroupName).Pr.Unit_Position)

■Setting value of the position command unit

Setting value	Position command unit
H00	pulse
H01	m
H41	degree
HB4	Revolution
HC0	inch
HFF	An arbitrary unit character string*1

*1 For setting an arbitrary unit character string, set Position Command Unit String (AxisName(AxesGroupName).Pr.Unit_PositionString). (A blank can also be set.)

■Setting value of the prefix

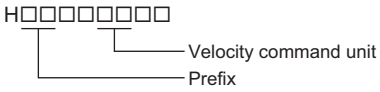
When the position command unit setting is HFF (an arbitrary unit character string), this setting is ignored and the control is operated with H00 ($\times 10^0$).

Setting value	Prefix
H00	$\times 10^0$
HFD	$\times 10^{-3}$ [m]
HFA	$\times 10^{-6}$ [μ]
HF7	$\times 10^{-9}$ [n]

■Display examples

The following is a display example of Position Command Unit Display (AxisName(AxesGroupName).Md.Unit_PositionDisplay) according to the setting values of Position Command Unit (AxisName(AxesGroupName).Pr.Unit_Position).

Ex.



Setting values of Position Command Unit (AxisName(AxesGroupName).Pr.Unit_Position) and Position Command Unit Display (AxisName(AxesGroupName).Md.Unit_PositionDisplay)

Position Command Unit (AxisName(AxesGroupName).Pr.Unit_Position)	Position Command Unit Display (AxisName(AxesGroupName).Md.Unit_PositionDisplay)
H00010000	m
HFD010000	mm
HFA010000	μm
HF7010000	nm
H00B40000	Revolution
H00410000	degree
HFA410000	$\times 10^{-6}$degree
H00000000	pulse
H00C00000	inch

Point

If "1" is set in the program when Position Command Unit (AxisName(AxesGroupName).Pr.Unit_Position) is "HFD010000", the position will be regarded as "1.0mm".

Velocity command unit (AxisName(AxesGroupName).Pr.Unit_Velocity)

■Setting value of the velocity command unit

Setting value	Velocity command unit
H03	s
H47	min

■Setting value of the prefix

Setting value	Prefix
H00	$\times 10^{0}$
HFD	$\times 10^{-3}$ [m]
HFA	$\times 10^{-6}$ [μ]
HF7	$\times 10^{-9}$ [n]

■Display examples

The following shows display examples of Velocity Command Unit Display (AxisName(AxesGroupName).Md.Unit_VelocityDisplay) according to the setting value of Velocity Command Unit (AxisName(AxesGroupName).Pr.Unit_Velocity).

Ex.

Setting values of Velocity Command Unit (AxisName(AxesGroupName).Pr.Unit_Velocity) and Velocity Command Unit Display (AxisName(AxesGroupName).Md.Unit_VelocityDisplay)

Velocity Command Unit (AxisName(AxesGroupName).Pr.Unit_Velocity)	Velocity Command Unit Display (AxisName(AxesGroupName).Md.Unit_VelocityDisplay)
H00004700	[Position command unit]/min
HFD000300	[Position command unit]/ms
HFA000300	[Position command unit]/μs
HF7000300	[Position command unit]/ns

Point

- If Position Command Unit (AxisName(AxesGroupName).Pr.Unit_Position) is "HFF000000 (an arbitrary unit character string)", the number of displayable characters from the beginning out of the position command unit strings is displayed on Velocity Command Unit Display (AxisName(AxesGroupName).Md.Unit_VelocityDisplay).
- If "1" is set in the program when Velocity Command Unit (AxisName(AxesGroupName).Pr.Unit_Velocity) is "HFD000300", the velocity will be regarded as "1.0 [position command unit]/ms".

- The following shows display examples of Velocity Command Unit Display (AxisName(AxesGroupName).Md.Unit_VelocityDisplay) according to the setting value of Position Command Unit (AxisName(AxesGroupName).Pr.Unit_Position) and Velocity Command Unit (AxisName(AxesGroupName).Pr.Unit_Velocity).

Ex.

Setting values of Position Command Unit (AxisName(AxesGroupName).Pr.Unit_Position) and Velocity Command Unit (AxisName(AxesGroupName).Pr.Unit_Velocity) and Velocity Command Unit Display (AxisName(AxesGroupName).Md.Unit_VelocityDisplay)

Position Command Unit (AxisName(AxesGroupName).Pr.Unit_Position)	Velocity Command Unit (AxisName(AxesGroupName).Pr.Unit_Velocity)	Velocity Command Unit Display (AxisName(AxesGroupName).Md.Unit_VelocityDisplay)
HFD010000	HFD000300	[mm/ms]

Combination of command units during multiple axes positioning control

During multiple axes positioning control, set command units of the axes group and the interpolation axes to be matched.
When the command units are mismatched, specify the input value of FB as shown below.

- For the input (such as Target position (Position) and Movement amount (Distance)) regarding position in multiple axes positioning control, be sure to specify the value based on the position command unit of each interpolation axis.
- For the input (Velocity (Velocity), Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk)) of multiple axes positioning control, be sure to specify the value based on the velocity command unit used for each control.

Velocity command units used for each control are shown below.
The following operations depend on interpolation controls.

■Linear interpolation control (MCv_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control), MCv_MoveLinearInterpolateRelative (Relative Value Linear Interpolation Control))

Velocity Mode (VelocityMode)	Operation
0: Vector Velocity (VectorSpeed)	• The movement amount on the linear path (combined movement amount) is calculated from the value of current position and Target position (Position) or Movement amount (Distance). The position command unit of the axes group and the interpolation axes is not affected. • The unit of the axes group is used for the velocity command unit in controlling.
1: Long Axis Velocity (LongAxisSpeed)	• The axis whose movement amount value is the largest is regarded as the long axis from the value of current position and Target position (Position) or Movement amount (Distance). The position command unit of the axes group and the interpolation axes is not affected. • The unit of the long axis is used for the velocity command unit in controlling. Unit of the axes group is not used.
2: Reference Axis Velocity (ReferenceAxisSpeed)	• The unit of the reference axis (First element of Linear interpolation axes (LinearAxes)) is used for the velocity command unit in controlling.

For details on linear interpolation control, refer to the following.
☞ Page 649 Linear interpolation control

■Circular interpolation control (MCv_MoveCircularInterpolateAbsolute (Absolute Value Circular Interpolation Control), MCv_MoveCircularInterpolateRelative (Relative Value Circular Interpolation Control))

- Calculates circular path from the value of current position, Sub point (AuxPoint), and End point (EndPoint). The position command unit of the axes group and the configuration axes is not affected.
- The unit of the axes group is used for the velocity command unit in controlling.

For details on circular interpolation control, refer to the following.
☞ Page 655 Circular interpolation control

■Operation when axes group unit and interpolation axes unit are mismatched

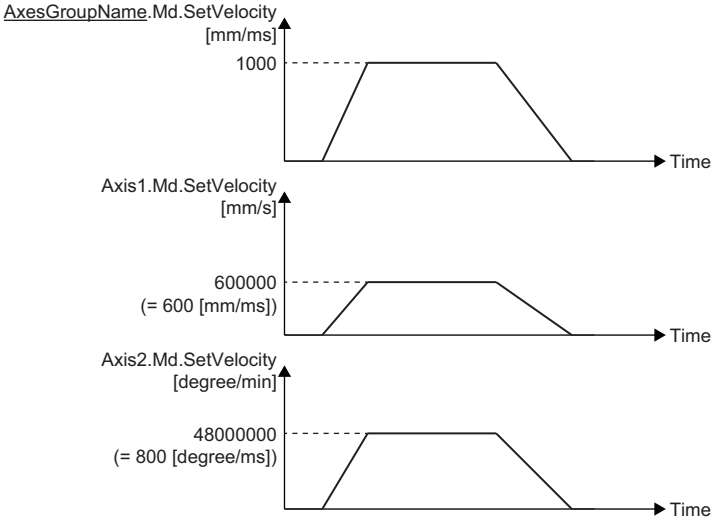
The following shows the operation example when the position/velocity command units of the configuration axis 1 and 2, and axes group in linear interpolation control are different.

Ex.

Operation example

- Axis setting and Axes group setting

Setting item	Setting details	Setting value
Position/Velocity command unit of the axes group	mm/ms	Position Command Unit (AxesGroupName.Pr.Unit_Position): HFD010000 Velocity Command Unit (AxesGroupName.Pr.Unit_Velocity): HFD000300
Position/Velocity command unit of the configuration axis 1	mm/s	Position Command Unit (AxisName.Pr.Unit_Position): HFD010000 Velocity Command Unit (AxisName.Pr.Unit_Velocity): H00000300
Position/Velocity command unit of the configuration axis 2	degree/min	Position Command Unit (AxisName.Pr.Unit_Position): H00410000 Velocity Command Unit (AxisName.Pr.Unit_Velocity): H00004700



- FB input (MCv_MoveLinearInterpolateRelative (Relative Value Linear Interpolation Control))

Setting item	Setting value
Linear interpolation axes (LinearAxes[0])	1
Linear interpolation axes (LinearAxes[1])	2
Linear interpolation axes (LinearAxes[2])	0
Movement amount (Distance[0])	300
Movement amount (Distance[1])	400
Velocity (Velocity)	1000
Velocity Mode (VelocityMode)	0: Vector Velocity (VectorSpeed)

<Operation>

- Linear interpolation is performed by Movement Amount (Distance) "300 [mm]" of the configuration axis 1, and "400 [degree]" of the configuration axis 2.
- Position and velocity command units of axes group are used for the unit of Velocity (Velocity) as a vector velocity. It will be controlled by the vector velocity at "1000 [mm/ms]".
- The motion system calculates a combined movement amount = $\sqrt{(300^2 + 400^2)}$ = 500 [mm] from each value of the configuration axis movement amount (Distance). Each axis movement amount of every operation cycle is calculated from the combined movement amount 500 [mm] and vector velocity 1000 [mm/s]. The calculated amount is commanded as a movement amount in the position command unit of each axis.
  The motion system calculates positioning speed of each axis as follows.
  A monitor value of each axis speed is stored by the velocity command unit of each axis.

Positioning speed of each axis	Calculated value
Positioning speed of configuration axis 1	1000 × 300 / 500 = 600 [mm/ms] (= 600000 [mm/s])
Positioning speed of configuration axis 2	1000 × 400 / 500 = 800 [degree/ms] (= 48000000 [degree/min])

Precautions

- For Out of Position Command Unit Range Warning (event code: 00D2DH), the initial value is stored in Position Command Unit Display (AxisName(AxesGroupName).Md.Unit_PositionDisplay). (Default value of position command unit: pulse)
- For Out of Velocity Command Unit Range Warning (event code: 00D2EH), the initial value is stored in Velocity Command Unit Display (AxisName(AxesGroupName).Md.Unit_VelocityDisplay). (Velocity command unit: pulses/s)
- Even if Position Command Unit (AxisName(AxesGroupName).Pr.Unit_Position), Velocity Command Unit (AxisName(AxesGroupName).Pr.Unit_Velocity), and Position Command Unit String (AxisName(AxesGroupName).Pr.Unit_PositionString) are changed, the homing request will not become TRUE.

24.2 Positioning Range

"Positioning Range" is "-10000000000.0 ≤ positioning range < 10000000000.0".
The range of Set Position (AxisName.Md.SetPosition) is determined by Ring Counter Upper Limit Value (AxisName.PrConst.RingCount_UpperValue) and Ring Counter Lower Limit Value (AxisName.PrConst.RingCount_LowerValue).

Relevant variables

Axis parameter constant (AxisName.PrConst.)

Variable/structure name	Name	Details
RingCount_Enable	Ring Counter Enabled Selection	Selects the ring counter enable/disable. • FALSE: Disabled*1 • TRUE: Enabled*2
RingCount_UpperValue	Ring Counter Upper Limit Value	Sets the ring counter upper limit value.*3 • -10000000000.0 to 10000000000.0
RingCount_LowerValue	Ring Counter Lower Limit Value	Sets the ring counter lower limit value.*3 • -10000000000.0 to 10000000000.0

*1 The range is "-10000000000.0 ≤ positioning range < 10000000000.0".
*2 If the ring counter upper/lower limit value is set to match the positioning range, the ring counter will be disabled.
*3 The value is not fetched when the ring counter is disabled.

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
SetPosition	Set Position	Stores the current position address.*1 The set position is a value which the cumulative current value is rounded with the ring counter range.
CumulativePosition	Cumulative Current Position	Stores the current position address. When the current position is changed, the address is changed to the one after change. The ring address is "-10000000000.0 ≤ cumulative current position < 10000000000.0".
FeedMachinePosition	Machine Feed Value	Stores the current position address by the machine coordinate. The accumulative value from the homing completed position is set. The address is not changed even if the current position is changed. The ring address is "-10000000000.0 ≤ Machine feed value < 10000000000.0".
CommandedPosition	Commanded Position	Stores Target position (Position)/Movement amount (Distance) imported by the positioning control FB being controlled. Stores "0" after the positioning is completed.
ActualPosition	Actual Position	Stores the actual current position. The value of "current position × driver unit conversion denominator / driver unit conversion numerator" is set. For details, refer to the following. ☞ Page 1130 Driver Unit Conversion Function The actual position is a value which is rounded with the ring counter range.

*1 The stored value includes an error because a floating-point error occurs.

Set position

Set Position (AxisName.Md.SetPosition) can be set to an arbitrary ring address by setting Ring Counter Upper Limit Value (AxisName.PrConst.RingCount_UpperValue) and Ring Counter Lower Limit Value (AxisName.PrConst.RingCount_LowerValue). The Ring Counter Upper Limit Value/Ring Counter Lower Limit Value can be set within the range of -10000000000.0 to 10000000000.0.

Restrictions

The motion control uses the real number data (floating-point data) for the axis current position, instruction target position, or others. Therefore, it may include the truncation error.

Ex.

When the positioning of relative position specification such as MC_MoveRelative (Relative Value Positioning) is executed repeatedly

Truncation errors may accumulate between the set position and the specified movement value.

If the truncation error is a problem, execute the positioning of absolute position specification such as MC_MoveAbsolute (Absolute Value Positioning).

Ex.

When positioning for automatic deceleration at a low speed

When the target position is reached, Overrun warning (event code: 00D10H) or Overrun error (error code: 1AE3H) may be detected due to a truncation error.

By configuring the settings so that digits after the decimal point are not included in real data type parameters related to the motion control, truncation errors caused by the real number data processing inside the function can be suppressed.

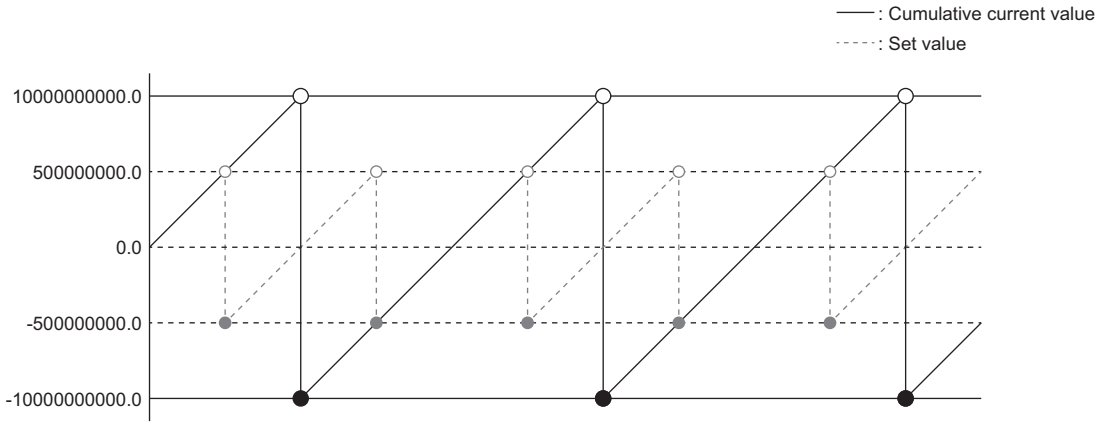
When the truncation error is a problem in setting (A), the setting (B) becomes a change candidate.

- Setting (A)

Setting item	Setting details
Position Command Unit*1	[mm]
Ring Counter Upper Limit Value	100.3 [mm]
Ring Counter Lower Limit Value	-100.7 [mm]
The minimum scale of the target position/movement amount specified by FB input	0.05 [mm]

- Setting (B)

Setting item	Setting details
Position Command Unit*1	[μm]
Ring Counter Upper Limit Value	100300 [μm]
Ring Counter Lower Limit Value	-100700 [μm]
The minimum scale of the target position/movement amount specified by FB input	50 [μm]



*1 For details on the setting method, refer to the following.
☞ Page 490 Units

Control details

Set Position (AxisName.Md.SetPosition) to be the ring address is calculated based on Cumulative Current Position (AxisName.Md.CumulativePosition). The cumulative current position will be the ring address of "-10000000000.0 ≤ cumulative current position < 10000000000.0" regardless of the setting of the Ring Counter Upper Limit Value/Ring Counter Lower Limit Value.

Ex.

The Ring Counter Lower Limit Value is "-500000000.0" and the Ring Counter Upper Limit Value is "500000000.0"
Set Position is the ring address of "-500000000.0 ≤ Set Position < 500000000.0".

The ring counter upper/lower limit value is fetched to the parameter at the timing when the axis is enabled.

Combination with other functions

The available range of positioning differs depending on the type of the positioning control FB.

- Absolute position specification: Within the range of the ring counter
- Relative position specification: Maximum movement amount | 10000000000.0 |

Precautions

When Ring Counter Enabled Selection (AxisName.PrConst.RingCount_Enable) is "TRUE (Enabled)", error is checked.
If the Ring Counter Upper Limit Value/Ring Counter Lower Limit Value is set as follows, an error will occur.

- The ring counter upper/lower limit value is set outside the positioning range.
- The ring counter lower limit value > The ring counter upper limit value
- | The ring counter upper limit value - The ring counter lower limit value | < 2.0

24.3 Velocity Range

Relevant variables

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
SetVelocity	Set Velocity	Stores the set output velocity.*1 This velocity is calculated from the difference of the set position. The value is positive when moving in the positive direction (Address increase direction), and the value is negative when moving in the negative direction (Address decrease direction). Stores the set velocity of the configuration axis during the axes group operation.
CommandedVelocity	Commanded Velocity	Stores the commanded velocity imported by the motion FB being controlled. Stores "0.0" after the control is completed. Stores "0.0" in Commanded Velocity (AxisName.Md.CommandedVelocity) of the configuration axis during the axes group operation.
TargetVelocity	Target Velocity	Stores the actual target velocity whose override and velocity limit value are considered. Stores "0.0" after the control is completed. Stores "0.0" in Target Velocity (AxisName.Md.TargetVelocity) of the configuration axis during axes group operation. ■For the positioning control FB The value becomes "0.0" or more regardless of the movement direction. ■For other than the positioning control FB The value is positive when moving in the positive direction (Address increase direction), and the value is negative when moving in the negative direction (Address decrease direction).
ActualVelocity	Actual Velocity	Stores the actual velocity. This velocity is calculated from the difference of the actual position. The value is positive when moving in the positive direction (Address increase direction), and the value is negative when moving in the negative direction (Address decrease direction).

*1 The stored value includes an error because a floating-point error occurs.

Axes group monitor data (AxesGroupName.Md.)

Variable/structure name	Name	Details
SetVelocity	Set Velocity	Stores the set output velocity during the axes group operation. The value becomes "0.0" or more regardless of the movement direction of the configuration axis. Stores "0.0" after the control is completed. * When "1: Long Axis Velocity (LongAxisSpeed)" or "2: Reference Axis Velocity (ReferenceAxisSpeed)" is specified in Velocity Mode (VelocityMode) of the linear interpolation control, the absolute value of set velocity of the relevant axis is stored.
CommandedVelocity	Commanded Velocity	Stores the commanded velocity imported by the motion FB being controlled. Stores "0.0" after the control is completed. * When "1: Long Axis Velocity (LongAxisSpeed)" or "2: Reference Axis Velocity (ReferenceAxisSpeed)" is specified in Velocity Mode (VelocityMode) of the linear interpolation control, the commanded velocity of the relevant axis is stored.
TargetVelocity	Target Velocity	Stores the actual target velocity whose override and velocity limit value are considered. The value becomes "0.0" or more regardless of the movement direction of the configuration axis. Stores "0.0" after the control is completed. * When "1: Long Axis Velocity (LongAxisSpeed)" or "2: Reference Axis Velocity (ReferenceAxisSpeed)" is specified in Velocity Mode (VelocityMode) of the linear interpolation control, the target velocity of the relevant axis is stored.
ActualVelocity	Actual Velocity	Stores the actual velocity. It is the vector velocity of the actual velocity of the configuration axes. The value becomes "0.0" or more regardless of the movement direction of the configuration axis. Stores "0.0" when the axes group is invalid.

Velocity command range

The command velocity range in the motion system is as follows.

Name	Description	Range
Commanded Velocity	Velocity that is specified in the motion FB	0, ±0.0001 to ±2500000000.0
Target Velocity	Actual command velocity whose override and velocity limit value are considered with the commanded velocity	

- For the valid range of the commanded velocity of each motion FB, refer to the specifications of each FB.
- Refer to the following for the operation when the target velocity goes out of range due to the use of the override function.

☞ Page 1116 Override Function

- When 0 is set to the commanded velocity in the FB to execute multiple start, the commanded velocity of previous FB will be set. For details, refer to the following.

☞ Page 547 Multiple Start (Buffer Mode)

- To perform floating-point operation, the lower limit value of the commanded velocity is limited by the following restrictions.

If the velocity converted from the commanded velocity to operation cycle is less than 0.00001, Out of operation cycle converted velocity range (error code: 1B16H) (when changing the velocity, Out of operation cycle converted velocity range warning (event code: 00D2FH) occurs.

To improve the precision of floating-point operation, specify the speed that is converted into operation cycle so as not to be less than 0.00001 by changing Position Command Unit (AxisName(AxesGroupName).Pr.Unit_Position) or Velocity Command Unit (AxisName(AxesGroupName).Pr.Unit_Velocity).

Ex.

When the operation cycle is "0.5 [ms]" and the commanded velocity is set with the following units

If the command velocity is specified for "0.0001" with the following units, the operation cycle converted velocity is as follows.

Variable name	Setting value	Unit
Position Command Unit (AxisName(AxesGroupName).Pr.Unit_Position)	H00000000	1×10^{0} [pulse]
Velocity Command Unit (AxisName(AxesGroupName).Pr.Unit_Velocity)	H00000300	1×10^{0} [pulse/s]

Operation cycle converted velocity = 0.0001 [pulse/s] ÷ 1000 × 0.5 [ms] = 0.00000005 [pulse]

Out of operation cycle converted velocity range (error code: 1B16H) occurs.

If Position Command Unit (AxisName(AxesGroupName).Pr.Unit_Position) is changed from "[pulse] (H00000000)" to "$\times 10^{-3}$ [pulse] (HFD000000)", and the command velocity is changed to "0.1", the operation cycle converted velocity is as follows.

Operation cycle converted velocity = 0.1×10^{-3} [pulse/s] ÷ 1000 × 0.5 [ms] = 0.00005×10^{-3} [pulse]. Thus an error can be avoided by changing the commanded velocity to match the change of the position command unit.

Precautions

When "0 < velocity after velocity override < 0.0001" occurs, Out of Velocity Range Clamping Warning (event code: 00D34H) occurs and the velocity will become 0.

24.4 Servo ON/OFF

This function executes servo ON/OFF of the real axis connected to the motion system.
The real axis can be operated by servo ON.

Operation of this function for each system status

○: Available, ×: Not available

System status	Operation availability
STOP	×
RUN	○
Moderate error	×
Major error	×

Relevant variables

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
Driver_ReadyOn	Driver Ready On Status	Displays the status of the drive unit to be connected. Becomes TRUE when Driver Status (AxisName.Md.Driver_State) of the connected driver is as follows. • 2: Fault Reaction Active (FaultReactionActive) • 5: Switched On (SwitchedOn) • 6: Operation Enable (OperationEnable) • 7: Quick Stop Active (QuickStopActive)
Driver_ServoOn	Driver Servo On Status	Displays the status of the drive unit to be connected. Becomes TRUE when Driver Status (AxisName.Md.Driver_State) of the connected driver is as follows. • 6: Operation Enable (OperationEnable) • 7: Quick Stop Active (QuickStopActive)

Relevant FBs

For details on motion control FBs, refer to the following.
MELSEC MX Controller MX-R Model Programming Manual

Motion control FB	Name	Description
MC_Power	Operation possible	Switches a specified axis to the operation possible status.
MCv_AllPower	All axes operation possible	Switches every axis to the operation possible status.

Control details

Servo ON/OFF

The servo ON/OFF of the real axis connected to the motion system is controlled by MC_Power (operation possible) for single axis and MCv_AllPower (all axes operation possible) for all axes.

For the drive unit status, refer to the following.

☞ Page 503 Drive unit state transition

■MC_Power (Operation Available) input/output and servo ON/OFF status

The servo ON/OFF status and the drive unit status of the selected axis can be switched as follows by inputting Enable (Enable) and Servo ON request (ServoON) of MC_Power (Operation Available).

Input variables		Output variables		Servo ON/OFF status	Driver Status (AxisName.Md.Driver_State)
Enable (Enable)	Servo ON request (ServoON)	Ready ON status (ReadyStatus)	Operable (Status)		
TRUE	TRUE	TRUE	TRUE	Servo ON	6: Operation Enable (OperationEnable)
	FALSE	TRUE	FALSE	Servo OFF	5: Switched On (SwitchedOn)
FALSE	TRUE	FALSE	FALSE	Servo OFF	3: Switched On Disabled (SwitchOnDisabled)
	FALSE	FALSE	FALSE	Servo OFF	3: Switched On Disabled (SwitchOnDisabled)

- If the real axis is rotated by external force during the servo OFF status, follow up processing is performed.
- The servo ON/OFF control can be operated regardless of the control mode. The control mode during the servo OFF status depends on the drive unit specification.
- While the drive unit error occurs, since the MC_Power (Operation Available) instruction/MCv_AllPower (All Axes Operation Available) instruction has been sent to the drive unit, Enable (Enable) and Servo ON request (ServoON) are not required to be turned from FALSE to TRUE again.

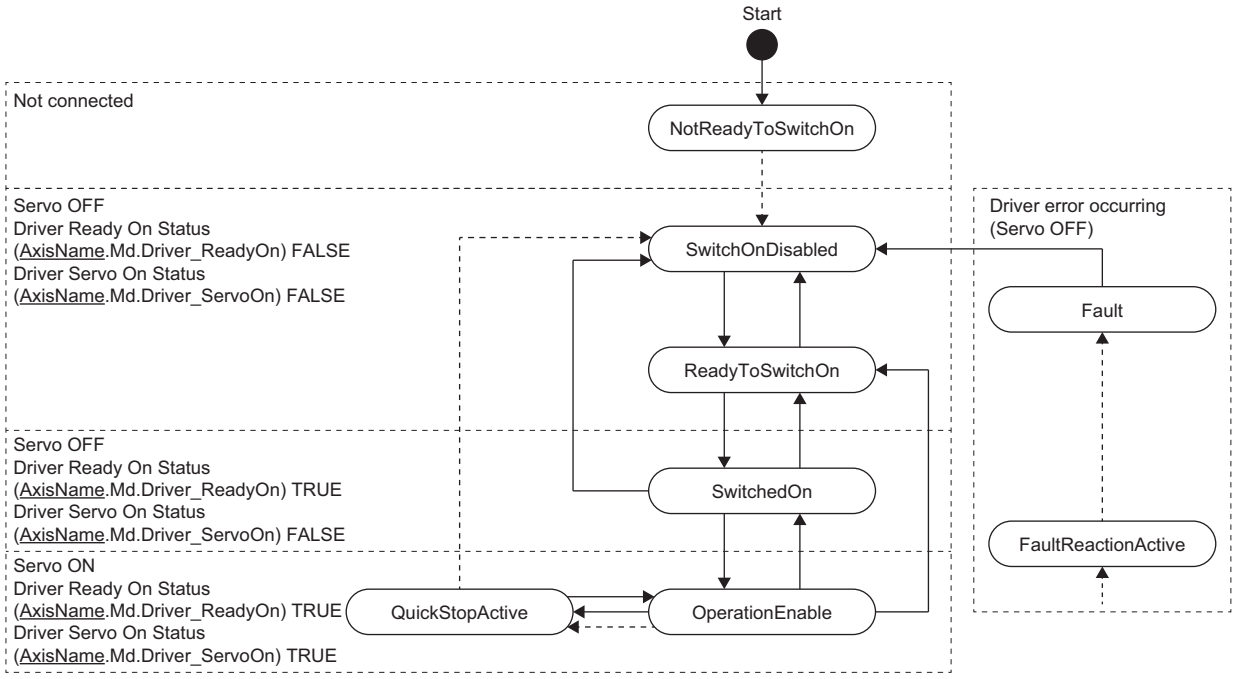
■Input/Output of MCv_AllPower and servo ON/OFF status

The servo ON/OFF status and the drive unit status of all real axes can be switched as follows by inputting Enable (Enable) and Servo ON request (ServoON) of MCv_AllPower (All Axes Operation Available).

Input variables		Servo ON/OFF status	Driver Status (AxisName.Md.Driver_State)
Enable (Enable)	Servo ON request (ServoON)		
TRUE	TRUE	Servo ON	6: Operation Enable (OperationEnable)
	FALSE	Servo OFF	5: Switched On (SwitchedOn)
FALSE	TRUE	Servo OFF	3: Switched On Disabled (SwitchOnDisabled)
	FALSE	Servo OFF	3: Switched On Disabled (SwitchOnDisabled)

- If the real axis is rotated by external force during the servo OFF status, follow up processing is performed.
- The servo ON/OFF control can be operated regardless of the control mode. The control mode during the servo OFF status depends on the drive unit specification.
- While the drive unit error occurs, since the MC_Power (Operation Available) instruction/MCv_AllPower (All Axes Operation Available) instruction has been sent to the drive unit, Enable (Enable) and Servo ON request (ServoON) are not required to be turned from FALSE to TRUE again.

Point



To individually execute servo OFF when using MCv_AllPower (All Axes Operation Available), use MC_Power (Operation Available) together. When MCv_AllPower (All Axes Operation Available) and MC_Power (Operation Available) are used together, the command of MC_Power (Operation Available) is given priority.

Drive unit state transition

The connected drive unit as an axis operates according to the status transition defined by the CiA402 drive profile shown below. The motion system determines whether the drive unit is being servo ON or OFF status based on the current drive unit status.

The current drive unit status can be monitored by Driver Status (AxisName.Md.Driver_State).

For details, refer to the manual of the drive unit to be connected.

Precautions

- MC_Power (Operation Available) establishes the axis information the first time that an instruction is called after PLC READY (MotionSystem.Cd.SequenceReady) is switched to on. Even if the axis information is changed while Enable (Enable) is FALSE, the change is not reflected.
- Do not set two or more MC_Power (Operation Available) for one axis. The operation is not guaranteed if set.
- The servo ON/OFF status when the program is stopped is maintained while built-in motion ready [X20] is off.

Relevant add-ons

The following add-ons are required to use this function.

- Axis
- MotionEngine
- MotionControl_General

24.5 Follow Up

This function reflects the input (current position) from the axis-assigned device station in the set position of the axis.
In an axis which has the current position (Position actual value) as the object data, this function can convert the unit of the current position by the driver unit conversion numerator/denominator (electronic gear) and reflect in the set position.

Axis type	Description
Real drive axis	The current position of the drive unit is converted and reflected in the set position in the servo OFF status. For this processing, even if the current position of the drive unit is moved during servo OFF, the drive unit will not move by the amount of droop pulses and can execute positioning from the stop position when the servo ON occurs next time. For the following cases, the follow up is executed even when the servo status is on. • When operating in a driver control mode other than cyclic synchronous position mode (csp) • The driver control mode of the drive unit is connected by motion system axis control unsupported mode.
Real encoder axis	This function can convert the unit of the current position of the synchronous encoder and reflect it in the set position. By switching the follow up enabled/disabled allows input enabled/disabled from the synchronous encoder.
Virtual encoder axis	

Operation of this function for each system status

○: Available, ×: Not available

Status	Operation availability
STOP	○
RUN	○
Moderate error	○*1
Major error	×

*1 Operation may not be performed depending on the status of add-ons and device stations.

Relevant variables

Axis parameter constant (AxisName.PrConst.)

Variable/structure name	Name	Details
Encoder_CounterDisableSignal	Counter Disabling Signal	Sets a signal to switch to the counter disable. The following shows the specific setting and the operation of Counter Disabling Signal (Encoder_CounterDisableSignal). ■Target (Source.Target) Only [VAR], [DEV], and [CONST] can be specified for data type. Only "Synchronous" can be specified for the network synchronous communication setting of the device station being referred to when [VAR] or [DEV] is specified. ■Signal detection method (Detection) Only the following level detections can be set. • 0: Detection at TRUE (HighLevel) • 1: Detection at FALSE (LowLevel) ■Compensation time (CompensationTime) Only "0.0 [s]" can be specified. ■Filter time (FilterTime) The setting range is "0.0 to 5.0 [s]". * If a value outside the range is set, Out of parameter range (axis) (error code: 1A60H) occurs.

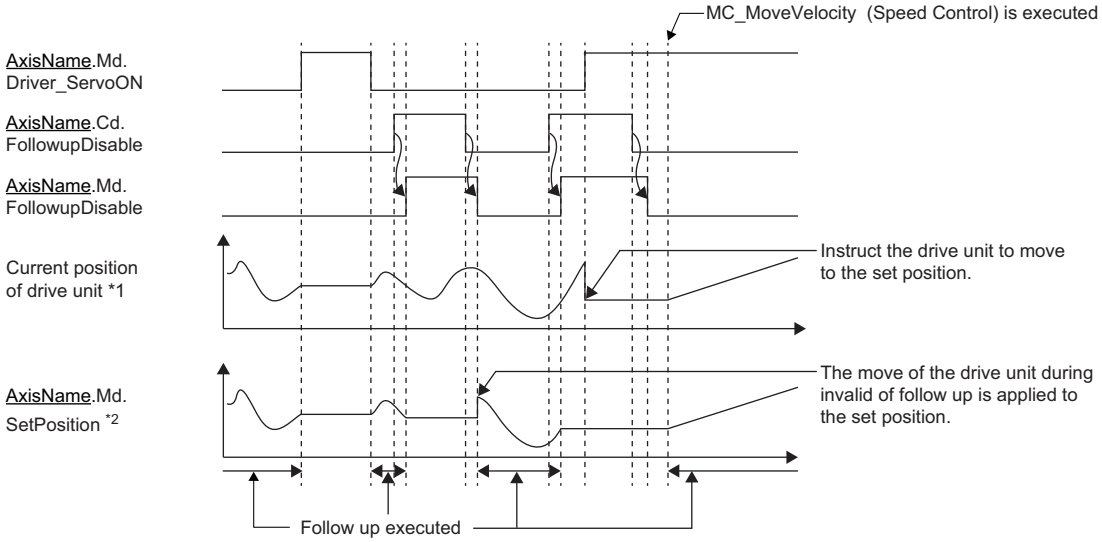
Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
FollowupDisable	Follow-up Disabled	Displays the follow up disable status. When it is disabled, the follow up is not executed. • FALSE: Follow-up enabled • TRUE: Follow-up disabled
Encoder_CounterDisable	Counter Disabled	Becomes TRUE while disabling the input from the synchronous encoder. • FALSE: Counter enabled • TRUE: Counter disabled
Io_PosActualValue	Object Data_PosActualValue	Follow up can be used in the axis which has this object data.

Axis control data (AxisName.Cd.)

Variable/structure name	Name	Details
FollowupDisable	Follow-up Disabled	Disables follow up. • FALSE: Not execute • TRUE: Execute the follow-up disable request
Encoder_CounterDisable	Counter Disabled	Switches to the counter disable. • FALSE: Not execute • TRUE: Execute the counter disable request

Disabling follow up



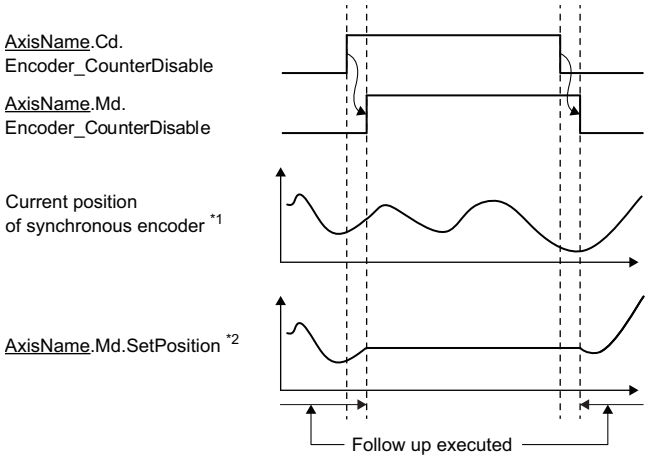
The follow up enabled/disabled status can be switched for each axis (default status: enabled). Input (current position) from the device station whose axis assignment has been executed is disabled and not reflected in the set position.

Point

That the follow up enabled/disabled is switched is recorded in the event history. Also, for the real drive axis, the servo ON from the follow up disabled status during the servo OFF is recorded in the event history as well. At this time, the difference [driver-based] between the drive unit target position (Target position) and the current position (Position actual value) is also recorded in the event history.

For real drive axis

Follow-up Disabled (AxisName.Md.FollowupDisable) becomes TRUE by setting Follow-up Disabled (AxisName.Cd.FollowupDisable) to TRUE, and the follow up is disabled.

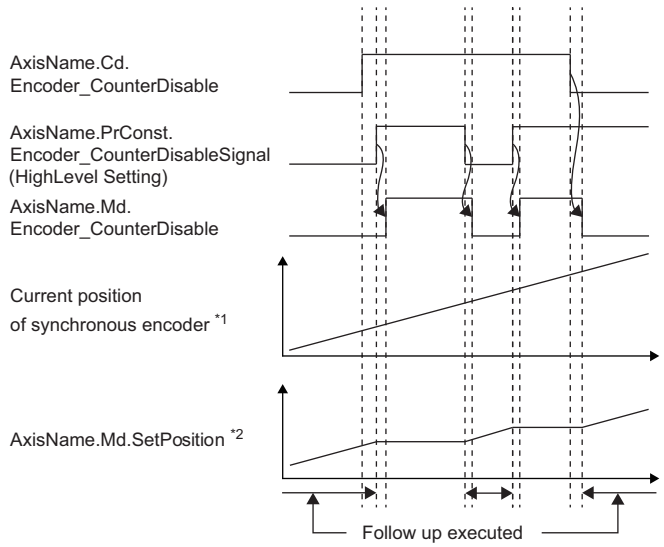


*1 When checking with the network label

*2 When driver unit conversion (Numerator / Denominator) is (1 / 1).

For real encoder axis/virtual encoder axis

■When Counter Disabling Signal (AxisName.PrConst.Encoder_CounterDisableSignal) is "no setting"

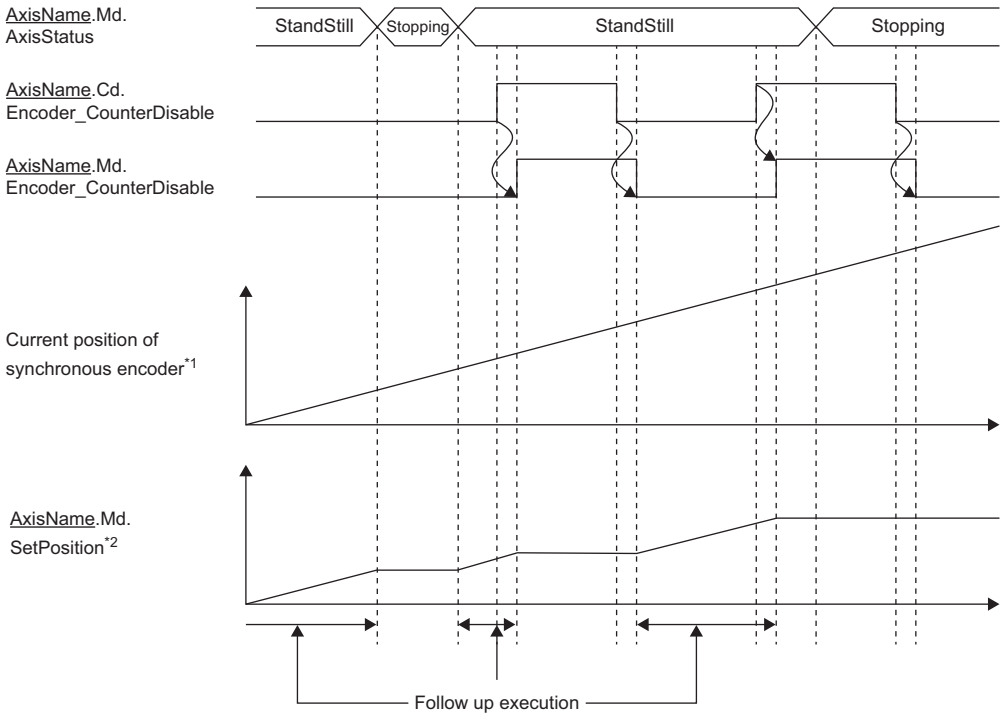


Counter Disabled (AxisName.Md.Encoder_CounterDisable) becomes TRUE by setting Counter Disabled (AxisName.Cd.Encoder_CounterDisable) to TRUE and the input from the synchronous encoder will be disabled.

*1 When checking with the network label
*2 When driver unit conversion (Numerator / Denominator) is (1 / 1).

■When Counter Disabling Signal (AxisName.PrConst.Encoder_CounterDisableSignal) is set

While Counter Disabled (AxisName.Cd.Encoder_CounterDisable) is TRUE, the counter disabling signal will be valid. Counter Disabled (AxisName.Md.Encoder_CounterDisable) becomes TRUE while the signal is in detection, and becomes the counter disable. While Counter Disabled (AxisName.Cd.Encoder_CounterDisable) is FALSE, the counter disable signal becomes invalid.



*1 When checking with the network label
*2 When driver unit conversion (Numerator / Denominator) is (1 / 1).

■When Axis Status (AxisName.Md.AxisStatus) is "0: Axis disabled (Disabled)", "1: Stopping on error (ErrorStop)", or "2: Decelerating to stop (Stopping)"

Follow-up is disabled while Axis Status (AxisName.Md.AxisStatus) is "0: Axis disabled (Disabled)", "1: Stopping on error (ErrorStop)", or "2: Decelerating to stop (Stopping)".

At this time, Counter Disabled (AxisName.Md.Encoder_CounterDisable) does not change.

Precautions

For real drive axis

- When the follow up is enabled after the current position of the drive unit is moved while the follow up is disabled, the motion system reflects the distance from the drive unit in the set position in one operation cycle. Therefore, when a single axis synchronous control is executed using an applicable axis as the master axis, the command of the movement amount of the set position is transmitted to the slave axis.
- The motion system outputs the distance to the drive unit in one operation cycle for the following cases. Note that a rapid operation may occur in the drive unit.
  - When the servo ON occurs next time after the current position of the drive unit is moved in the follow up disabled status during the servo OFF
  - When the system stopped in the servo ON status after the control excluding the position loop, such as the speed control, was executed with the follow up disabled status
- The software stroke limit function is invalid during the servo OFF. Therefore, set the software stroke limit in the slave axis or the following axis for safety to transmit the command under follow up in the single axis synchronous control to the slave axis.

For real encoder axis or virtual encoder axis

Follow up may not be performed depending on the status of the axis. For details, refer to the following.

☞ Page 455 Real encoder axis
☞ Page 461 Virtual encoder axis

For all axes types

When the movement amount per operation cycle exceeds the following range, the follow-up does not operate normally because the movement amount of the axis is different from the movement amount of the device station. Use the device stations so that their movement amount is within the following range.

Axis type	Valid range for available follow-up per operation cycle
Real drive axis	(Movement amount per operation cycle) [Driver unit] within signed 32-bit integral number range
Real encoder axis (Real encoder axes types: Via drive unit)	- ((Multiple revolution counter maximum value) / 2 × (Encoder resolution)) ≤ (Movement amount per operation cycle) [Encoder pulse unit] ≤ ((Multiple revolution counter maximum value) / 2 × (Encoder resolution) - 1)
Virtual encoder axis	- (Encoder ring counter upper limit value - Encoder ring counter lower limit value + 1) / 2 < (Movement amount per operation cycle) [Encoder pulse unit] < (Encoder ring counter upper limit value - Encoder ring counter lower limit value + 1) / 2

Relevant add-ons

The following add-ons are required to use this function.

- Axis
- MotionEngine

24.6 Absolute Position Control

This function restores the current position of an axis.

Absolute position system

The absolute position system maintains the current position of axes. The absolute position system configuration differs depending on the axis type. For details, refer to the following.

☞ Page 517 Current position restoration for each axis type

The absolute position data used in the absolute position system control is maintained inside the motion system as a backup file.

Current position restoration

This function restores the current position of the axis to the previous position when the motion system power is turned on again or reset or when a device station whose axis assignment has been executed is connected.

When a drive unit other than the MELSERVO is used, the current position is set after connection.

Whether to restore with the retained absolute position data or not can be specified in Absolute Position Control Setting (AxisName.PrConst.PosRestoration_AbsPosEnable) of the axis parameter. For details, refer to the following.

☞ Page 512 Current position restoration

Operation of this function for each system status

○: Available

System status	Operation availability
STOP	○
RUN	○
Moderate error	○
Major error	○*1

*1 Operation may not be performed depending on the error status.

Relevant variables

Axis parameter constant (AxisName.PrConst.)

Variable/structure name	Name	Details
PosRestoration_AbsPosEnable	Absolute Position Control Setting	Sets the absolute position control setting. • 0: Disable Absolute Position System (ABSDisabled) • 1: Enable Absolute Position System (Enabled) • -1: Automatic Setting (Acquire from Connected Device) (Auto)
PosRestoration_RestorationBase	Current Position Restoration Reference Position Setting	Sets the reference position of current position restoration to use the absolute position system. • 0: Backup Position (BackupPosition) • 1: Home Position (HomePosition) • -1: Automatic Judgment (Auto)

Axis parameter (AxisName.Pr.)

Variable/structure name	Name	Details
Homing_Required	Homing Required or Not	Sets whether homing is required or not. Sets FALSE when the homing is not required. If FALSE is set, the homing request will not become TRUE at the current position restoration. • FALSE: Homing is unnecessary. • TRUE: Homing is necessary.

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
Homing_Required	Homing Required or Not	Displays whether the axis requires the homing or not. If FALSE is set, the homing request will not become TRUE at the current position restoration. • FALSE: Homing is unnecessary. • TRUE: Homing is necessary.
PosRestoration_Status	Current Position Restoration Status	Displays the current position restoration status. • 0: Not Executed (NotExecute) • 1: Waiting for Restoration Request (WaitingRequest) • 2: Restoration Completed in Incremental System (RestoredInIncSystem) • 3: Restoration Completed in Absolute Position System (Homing Uncompleted) (RestoredInAbsSystemUnHomed) • 4: Restoration Completed in Absolute Position System (RestoredInAbsSystem) * When Current Position Restoration Request must be executed, "1: Waiting for Restoration Request (WaitingRequest)" is displayed upon connecting the device station. * "0: Not Executed (NotExecute)" is displayed when the device station is disconnected.
Homing_Request	Homing Request	Displays whether homing is required or not. The timing of becoming TRUE differs depending on the Absolute Position Control Setting (AxisName.PrConst.PosRestoration_AbsPosEnable). For details, refer to the following. ☞ Page 514 Homing request Becomes FALSE when the homing is completed. • FALSE: No homing request • TRUE: Homing request
SetPosition	Set Position	Stores the current position address. The set position is a value which rounds the cumulative current value with the ring counter range.
CumulativePosition	Cumulative Current Position	Stores the current position address. When the current position is changed, the address is changed to the one after change.
FeedMachinePosition	Machine Feed Value	Stores the current position address by the machine coordinate. The accumulative value from the homing completed position is set. The address is not changed even if the current position is changed.

Current position restoration

Specify whether the absolute position system is used for the current position restoration or not in Absolute Position Control Setting (AxisName.PrConst.PosRestoration_AbsPosEnable).

Absolute Position Control Setting (AxisName.PrConst.PosRestoration_AbsPosEnable)	Details
0: Disable Absolute Position System (ABSDisabled)	☞ Page 512 Incremental system
1: Enable Absolute Position System (Enabled)	☞ Page 513 Absolute position system
-1: Automatic Setting (Acquire from Connected Device) (Auto)	☞ Page 514 Connected device setting

- Set "-1: Automatic Setting (Acquire from Connected Device) (Auto)" when the connected device has the Encoder status 1 object.
- When "-1: Automatic Setting (Acquire from Connected Device) (Auto)" is not set, the connected device side setting and the motion system side setting must be matched. If not matched, normal current position control cannot be executed. (If the connected device has Encoder status 1 object and the settings are mismatched, Absolute position control setting mismatch (error code: 1AF2H) will occur at the current position restoration.)

Ex.

When the absolute position system is used,
select "1: Enabled (absolute position detection system)" for "Absolute position detection system selection (PA03.0)" of the servo parameter (basic parameter) in the MR-J5(W)-G. In the motion system, select "1: Enable Absolute Position System (Enabled)" for Absolute Position Control Setting (AxisName.PrConst.PosRestoration_AbsPosEnable) in the real drive axis which uses the MR-J5(W)-G as the connected device.
The current position restoration timing differs depending on the axis type. For details, refer to the following.
☞ Page 517 Current position restoration for each axis type

Point

Whether "incremental system" or "absolute position system" was used for the current position restoration is recorded in the event history.

- When "-1: Acquire from Connected Device" is set for an axis whose Encoder status 1 object setting value remains blank, Connection setting incorrect warning for drive units other than MELSERVO (event code: 00D4CH) will occur, and it will operate as "Incremental system".

Incremental system

This system restores the current position without using the absolute position data.
When the current position restoration is completed, the axis current position (Cumulative Current Position, Machine Feed Value) becomes "0", and the Homing Request (AxisName.Md.Homing_Request) becomes TRUE. (The set position may not become "0" depending on the ring counter setting. (☞ Page 496 Positioning Range))
When restoration is completed, Current Position Restoration Status (AxisName.Md.PosRestoration_Status) of the axis becomes "2: Restoration Completed in Incremental System (RestoredInIncSystem)".
If the machine position establishment with the device station is not required, set Homing Required or Not (AxisName.Pr.Homing_Required) to FALSE. This prevents Homing Request (AxisName.Md.Homing_Request) from becoming TRUE at the restoration.
The absolute position data backup is not executed.

Absolute position system

This system restores the current position using the absolute position data.
At the current position restoration, the axis current position (set position, cumulative current position, and machine feed value) is restored based on backed up absolute position data. When restoration is completed, Current Position Restoration Status (AxisName.Md.PosRestoration_Status) of the axis becomes "4: Restoration Completed in Absolute Position System (RestoredInAbsSystem)".
However, if Absolute Position Data Incorrect Warning (event code: 00D00H) has been detected at restoration, Current Position Restoration Status (AxisName.Md.PosRestoration_Status) of the axis becomes "3: Restoration Completed in Absolute Position System (Homing Uncompleted) (RestoredInAbsSystemUnHomed)". The current position is restored with the same content as the incremental system and Homing Request (AxisName.Md.Homing_Request) becomes TRUE. (The absolute position data is maintained.)
At this time, the absolute position system is not enabled until homing is completed. Be sure to execute homing. (When homing has been normally completed, Current Position Restoration Status (AxisName.Md.PosRestoration_Status) of the axis becomes "4: Restoration Completed in Absolute Position System (RestoredInAbsSystem)".)
When the absolute position system is used, the restoration content differs depending on the axis type. For details, refer to the following.
☞ Page 517 Current position restoration for each axis type
In the following cases, Absolute Position Data Incorrect Warning (event code: 00D00H) occurs.

- The absolute position data is illegal at the current position restoration by the following causes.
  - The axis type is changed. (The axis type of the absolute position data does not match the axis variable.)
  - The absolute position data is deleted by the memory error or others.
  - The homing request has been TRUE at backup.
  - The axis driver unit conversion (numerator/denominator) is changed.
- Even though the machine homing has been started, it has not been normally completed.
- For real drive axes, an error occurs by the following causes.
  - "Absolute position erased" is detected on the drive unit side.
  - "Polarity" b7: position polarity of the object data is changed.
  - "HomeOffset" of the object data is changed.
  - The connected drive unit was changed.
  - The encoder resolution of the connected drive unit was changed.
- For real encoder axes (via drive unit), an error occurs by the following causes.
  - "Absolute position erased" is detected in the scale measurement encoder.
  - The encoder resolution of the scale measurement encoder is changed.
- For virtual encoder axes, an error occurs by the following causes.
  - The encoder ring counter upper/lower limit values are changed.

The following object data is used to acquire the detection result of absolute position erased/current position restoration disabled on the drive unit side.

Setting item (AxisName.PrConst.SlaveObject.)	Application
vStatusDo1 (StatusDo1)	Used to determine the current position restoration availability and the absolute position erased on the drive unit side.
vStatusDo2 (StatusDo2)	Used to determine the absolute position erased on the drive unit side.
vSupportedStatusDo1 (SupportedStatusDo1)	Acquires the corresponding status for each bit of StatusDo1.
vSupportedStatusDo2 (SupportedStatusDo2)	Acquires the corresponding status for each bit of StatusDo2.

Precautions

- All setting values of object data used to acquire the detection result of absolute position erased/current position restoration disabled for the drive unit must be set. If even one setting value of object data used to acquire the detection result of absolute position erased/current position restoration disabled for the drive unit is blank, restoration to the correct position may not be possible.
- When a drive unit other than the MELSERVO is used, the detection result of absolute position erased for the drive unit is not acquired. When using an absolute position system with a drive unit other than the MELSERVO, execute the operation after checking that the drive unit is not in absolute position erased status. When the drive unit is in absolute position erased status, execute homing before executing the operation.

Connected device setting

The connected device that has the Encoder status 1 object in the real axis acquires the absolute position system setting by the SDO communication and restores the current position.
Set the absolute position system setting in the connected device side.
For virtual axes, the device operates as the incremental system.

Homing request

The Homing Request (AxisName.Md.Homing_Request) will be TRUE in the following cases.

Point

The reason why Homing Request (AxisName.Md.Homing_Request) became TRUE is recorded in event history.

Absolute Position Control Setting (AxisName.PrConst.PosRestoration_AbsPosEnable)*1	Cause		Detection timing*2
Common	The system power is turned on or reset.*3		At the system power-ON or after reset
	The axis type is changed.		At the current position restoration
	Homing is started. (The homing request flag will not become FALSE unless homing is normally completed.)		At homing start
	The axis driver unit conversion (numerator/denominator) is changed.		At the current position restoration When PLC READY (MotionSystem.Cd.SequenceReady) is turned on
	The drive unit power turns on.*3 (The real drive axis only)		At the current position restoration
Disable absolute position system	The current position restoration is executed.		At the current position restoration
Enable absolute position system	The absolute position data in the motion system has been erased due to an error such as a memory error.		At the current position restoration
	A change of the drive unit and the motor encoder is detected.		
	Only for real drive axes	"Polarity" b7: position polarity of the object data is changed.	
		An electronic gear on the drive unit side is changed.	
		"Absolute position erased" is detected on the drive unit side.	At the current position restoration and cause occurring
	Only for real encoder axes (via drive unit)	"Absolute position erased" is detected in the scale measurement encoder.	At the current position restoration
		The encoder resolution of the scale measurement encoder is changed.	
	Only for virtual encoder axes	The encoder ring counter upper/lower limit values are changed.	

*1 For the "-1: Automatic Setting (Acquire from Connected Device) (Auto)" setting, refer to the connected device setting.
*2 When Homing Required or Not (AxisName.Pr.Homing_Required) is FALSE, Homing Request (AxisName.Md.Homing_Request) will not become TRUE even though the cause is occurring at the current position restoration.
*3 When the system/drive unit power is off when "1: Enable Absolute Position System (Enabled)" is set and homing is completed at resetting, the homing request will not become TRUE.

Absolute position data backup

When the absolute position system is used, the absolute position data of each axis is backed up. The absolute position data is backed up with it linked to the axis variable (axis No.) and the axis type. At the current position restoration, if the setting values do not match with the axis variable (axis No.) and the axis type of the absolute position data, the absolute position data will be discarded. (Absolute Position Data Incorrect Warning (event code: 00D00H) occurs.)
At the current position restoration, if the setting values match with the axis variable (axis No.) and the axis type of the absolute position data, the absolute position data will be taken over even when the variable name is different.

Ex.
For the following operation, Axis0002 takes over the absolute position data of Axis0001.
- Delete the axis (Variable name: Axis0001, Axis number: 1, Axis type: Real drive axis) and execute writing.
- Add the axis (Variable name: Axis0002, Axis number: 1, Axis type: Real drive axis) and execute writing.
- Execute current position restoration.

Backup is executed while Homing Request (AxisName.Md.Homing_Request) is FALSE. (When Homing Request (AxisName.Md.Homing_Request) becomes TRUE, the absolute position data is discarded.)
Backup is executed at approximately 2 [s] intervals after the previous backup.

Storage folder and file name

The following shows the storage folder and file name of the backed up absolute position data.
- Storage folder: /lch
- File name: abs_axis.bin

Memory capacity

Memory capacity of the absolute position data differs depending on the axis type. Specify memory capacity of the absolute position data according to the axis type and the number of axes. The following table lists the maximum absolute position data size based on the specifications.

Axis type	Memory usage	Maximum memory capacity
Real Drive Axis	220 bytes/axis	56320 bytes (220 bytes × 256 axes)
Real Encoder Axis	170 bytes/axis	1700000 bytes (170 bytes × 10000 axes)
Virtual Drive Axis	90 bytes/axis	900000 bytes (90 bytes × 10000 axes)
Virtual Encoder Axis	170 bytes/axis	1700000 bytes (170 bytes × 10000 axes)
Virtual Linked Axis	90 bytes/axis	900000 bytes (90 bytes × 10000 axes)

Memory capacity used for the absolute position data can be specified in Maximum Backup RAM Size (System.PrConst.AddonAbsSystem.BackupRamSizeMax).
If the file size required for backup exceeds specified memory capacity when the current position of each axis is restored, Insufficient current position backup capacity (error code: 1B11H) occurs and the target axis is not restored completely. Check the memory capacity and turn on the system again or reset it.
Discarded absolute position data is deleted from the file when the system power is turned on again or reset.

Saving (backup) and restoration (restored) of the absolute position data

The absolute position data maintained inside the motion system can be backed up and restored using tools such as the engineering tool. When exchanging the motion module, restarting time can be shortened by saving/restoring not only programs and parameters but also the absolute position data.

During backup or restoration, the motion system stops backing up the absolute position data.

For the real drive axis, Homing Request (AxisName.Md.Homing_Request) becomes TRUE when the restored absolute position data is different from Home Offset (607CH), the device, and the resolution of the connected drive unit.

For details on saving (backup) and restoration (restored), refer to the following.

☞ Page 1622 CONTROLLER DATA BACKUP/RESTORATION FUNCTION

Point

- The current position of the moved axes after backup stop is not saved. It is recommended to execute the backup after checking all axes have stopped.
- When the current position is restored using the 32-bit restoration, if the value of the current position (Position actual value) has changed beyond the signed 32-bit integer range since the previous backup, the current position after the drive unit re-connection becomes an error value.

Current position restoration for each axis type

This section describes the current position restoration for each axis type.

Real drive axis

Each current position is restored as follows.

Current position		Incremental system	Absolute position system	
			Reference position	
			Backup position	Home position
Machine feed value		Restored to "0".	Differs depending on the restoration method. For details, refer to the following. ☞ Page 518 Absolute position system	—
Cumulative current position		—		The same value as restored machine feed value.
Set position	Ring counter enabled selection: Disabled	The same value as restored cumulative current position.		
	Ring counter enabled selection: Enabled	—	Restored to the backup data value.*1	A value obtained by rounding the restored machine feed value with the ring counter

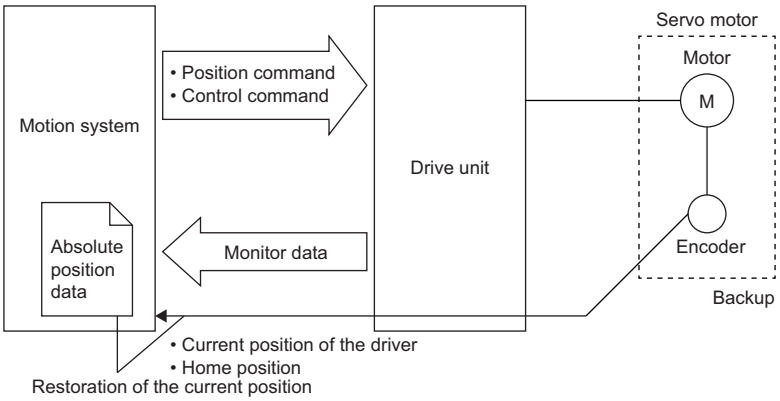
*1 If the setting value of the ring counter upper limit value or ring counter lower limit value is changed after homing, the position may not be restored correctly as the restoration is executed based on the backup data before the setting value is changed. Execute homing again.

When the current value is changed, the current position to be restored after the motion system or the drive unit is powered on again is as follows.

Current position		Reference position	
		Backup position	Home position
Machine feed value		—(Not subject to current position change)	
Cumulative current position		The position returns to the one before current position change.	The position returns to the one before current position change.
Set position	Ring counter enabled selection: Disabled		
	Ring counter enabled selection: Enabled	The position is the one after current position change.	

■Current position restoration timing

If object data required to construct the absolute position system for 64-bit current position restoration exist, restoration is automatically executed at the initial communication with the device station. For details on the absolute position system to execute the 64-bit current position restoration, refer to the following.



☞ Page 518 Absolute position system

The servo ON status is not established until the current position restoration is completed.

■Absolute position system

This section describes precautions for constructing the absolute position system in a real drive axis.

The following shows the absolute position system configuration when the drive unit is used as the servo amplifier.

A drive unit/servo motor which can detect the absolute position must be used to construct the absolute position system.

For details on the absolute position system setting of the drive unit side, refer to each drive unit manual.

For MR-J5(W)-G: MR-J5-G/MR-J5W-G User's Manual (Parameters)

The current position restoration of the absolute position system can be classified into the following four methods.

Current position restoration method	Reference position	Description	Remark
32-bit restoration (Drive unit current position restoration)	Backup position	Correctly executes the current position restoration within the signed 32-bit integral number range [driver-based] from the reference position. The position is restored using position data backed up by the motion system.	• If object data required to construct the 64-bit absolute position system are not set, 32-bit restoration will be executed. • 64-bit restoration is a restoration based on the home position when the connected device station has been changed.
	Home position	Correctly executes the current position restoration within the signed 32-bit integral number range [driver-based] from the reference position. The position is restored with respect to the drive unit current position.	
64-bit restoration (Drive unit ABS counter position restoration)	Backup position	Correctly executes the current position restoration within up to the signed 64-bit integral number range*1 [driver-based] from the reference position. The position is restored using position data backed up by the motion system.	
	Home position	Correctly executes the current position restoration within up to the signed 64-bit integral number range*1 [driver-based] from the reference position. The position is restored with respect to the drive unit current position.	

*1 Actual restoration possible range is shown below.
- ((Multiple revolution counter maximum value) / 2 × (Encoder resolution)) to ((Multiple revolution counter maximum value) / 2 × (Encoder resolution) - 1)

Point

In the real drive axis, which method was used for the current position restoration of the absolute position system, "32-bit restoration, 64-bit restoration (backup position), 32-bit restoration (home position), or 64-bit restoration (home position)" is recorded in the event history.

The following shows object data required to construct the 64-bit absolute position system.
If any one of the following parameters is not specified, 32-bit restoration is executed.

Setting item Object Data (AxisName.PrConst.SlaveObject) (SLAVE_OBJECT_REAL)	Setting details
vHomeCycleCounter (HomeCycleCounter)	Specifies the object ID storing the encoder position within one revolution at homing.
vHomeAbsCounter (HomeAbsCounter)	Specifies the object ID storing the encoder multiple revolution counter at homing.
vInitialPos (InitialPos)	Specifies the object ID storing Position actual value at connection.
vInitialCycleCounter (InitialCycleCounter)	Specifies the object ID storing the encoder position within one revolution at connection.
vInitialAbsCounter (InitialAbsCounter)	Specifies the object ID storing the encoder multiple revolution counter at connection.
vMaxAbsCounter (MaxAbsCounter)	Specifies the object ID storing the maximum value of the multiple revolution counter.

Precautions

- Even if the above parameters have been specified, Driver restoration data incorrect (error code: 1B12H (detail code: 0001H)) will occur and the current position restoration may not be completed. Execute reconnecting after correcting the parameter of the drive unit.
- When the maximum value of encoder resolution or encoder multiple revolution counter is other than 2 to the power of n, the 32-bit restoration is executed.
- When the 32-bit restoration is executed, if the value of Position actual value has changed beyond the signed 32-bit integer range during the drive unit disconnection, the current position after the drive unit connection becomes an error value. Execute homing if necessary.
- When the 32-bit restoration is executed, if a disconnection or power off occurs while the operation is being performed at a speed where the drive unit command velocity is 536870912U/s or higher, the current position may not be restored normally. Execute homing if necessary.
- When the MR-J5(W)-G cannot restore the current position, Driver restoration data incorrect (error code: 1B12H (detail code: 0002H)) will occur in the motion system, and the current position restoration is not completed. The current position may be restored by checking the status of the MR-J5(W)-G and reconnecting it. During reconnection, when homing request becomes TRUE, execute homing again.

■When the MR-J5(W)-G is used

The following explains the settings and the current position restoration method when the absolute position system is constructed using the MR-J5(W)-G.

- MR-J5(W)-G setting

Select "1: Enabled (absolute position detection system)" in "Absolute position detection system selection (PA03.0)" of the servo parameter (basic setting). In addition, select "0: Disabled" in "Absolute position counter warning (AL. E3) selection (PC29.5)" of the servo parameter (extension setting).
Depending on the "Electronic gear numerator (PA06)" and "Electronic gear denominator (PA07)" setting of the servo parameter, Driver restoration data incorrect (error code: 1B12H) may occur. Correct the following.

- When the resolution of the connected encoder is 2 to the power of n, set the electronic gear of the MR-J5(W)-G to be 1:1 or multiple of 2 to the power of n.
- When the resolution of the connected encoder is other than 2 to the power of n, set the electronic gear of the MR-J5(W)-G to "1:1".

- Motion system setting

Select "-1: Automatic Setting (Acquire from Connected Device) (Auto)" or "1: Enable Absolute Position System (Enabled)" in Absolute Position Control Setting (AxisName.PrConst.PosRestoration_AbsPosEnable) in the real drive axis whose connected device is the MR-J5(W)-G.

- Current position restoration method

Execute the 64-bit current position restoration.

Real encoder axis

Each current position is restored as follows.

Current position	Incremental system	Absolute position system
Cumulative current position	Restored to "0".	Restores the position based on the synchronous encoder movement amount by using backup data of the motion system. When the axis state transitions to Standby (Standstill) for the first time after restoration is complete, the movement amount from the completion of restoration is followed up.
Set position	A value obtained by rounding the restored cumulative current position with the ring counter	

The restoration method for the absolute position system depends on Real Encoder Axis Type Setting (AxisName.PrConst.Encoder_AxisType) of the axis parameter shown below.

Real encoder axis type	Current position restoration method	Description	Remark
Via drive unit	64-bit current position restoration	Correctly executes the current position restoration within up to the signed 64-bit integral number range*1 [encoder pulse unit] from the backup position.	Only the synchronous encoder connected to the drive unit can be used. For details on the setting, refer to the following. ☞ Page 443 Axis

*1 Actual restoration possible range is shown below.
- ((Multiple revolution counter maximum value) / 2 × (Encoder resolution)) to ((Multiple revolution counter maximum value) / 2 × (Encoder resolution) - 1)

■Current position restoration timing

Current position restoration is executed after the real drive axis of the same station address is connected.

Virtual drive axis

Each current position is restored as follows.

Current position	Incremental system	Absolute position system
Cumulative current position	Restored to "0".	Restored to the backup data value.
Set position	A value obtained by rounding the restored cumulative current position with the ring counter	

■Current position restoration timing

Current position restoration is executed at the axis variable initialization. For details on the axis variable initialization timing, refer to the following.

☞ Page 445 Axis variable initialization timing

Virtual encoder axis

Each current position is restored as follows.

Current position	Incremental system	Absolute position system
Cumulative current position	Restored to "0".	Restores the current position based on the movement amount from the backup data to the position at restoration. Correctly executes the current position restoration within the signed 32-bit integral number range [encoder pulse unit] from the backup position. When the axis state transitions to Standby (Standstill) for the first time after restoration is complete, the movement amount from the completion of restoration is followed up.
Set position	A value obtained by rounding the restored cumulative current position with the ring counter	

■Current position restoration timing

Executes the current position restoration as Connection Command (AxisName.Cd.Encoder_Connect) becomes TRUE.

Virtual linked axis

Each current position is restored as follows.

Current position	Incremental system	Absolute position system
Cumulative current position	Restored to "0".	Restored to the backup data value.
Set position	A value obtained by rounding the restored cumulative current position with the ring counter	

■Current position restoration timing

Current position restoration is executed at the axis variable initialization. For details on the axis variable initialization timing, refer to the following.

☞ Page 445 Axis variable initialization timing

Required object data

When executing 64-bit restoration for the real drive axis, refer to the following.

☞ Page 518 Absolute position system

Precautions

- In the absolute position control setting, when the connected device side setting and the motion system side setting are mismatched, normal current position control may not be executed. (If the connected device has Encoder status 1 object, Absolute position control setting mismatch (error code: 1AF2H) will occur at the current position restoration.)
- If Homing Required or Not (AxisName.Pr.Homing_Required) is set to TRUE, address information stored in the motion system is not guaranteed.
- A backup file created with a different model can be used. However, current position restoration can only be executed for the number of axes of the backup file.
  Example: When a backup file is created with a 4-axis model, and the backup file is moved to an 8-axis model, the current position restoration is executed for 4 axes and not for the remaining 4 axes.

Relevant add-ons

The following add-ons are required to use this function.

- Axis
- AbsSystem

25 OPERATION CYCLE

In the motion system, operation processing related to the motion control is performed in the fixed cycle (motion operation cycle). This section describes operation cycles which can be set in the motion system.
An operation cycle can include a mix of up to three cycles. A system with many axes can be controlled in divided manner by operating a specific axis at a fast operation cycle and operating other axes at a low speed operation cycle.

Operation of this function for each system status

○: Available, ×: Not available

System status	Operation availability
STOP	○
RUN	○
Moderate error	○
Major error	×

25.1 Relevant Variables

CYCLE_PARAM.

Variable/structure name	Name	Details
NumOfCycleOverWngDetectTimes	Number of Cycle Over Warning Detections	Sets the number of cycles until the cycle over warning of each cycle is detected. Warning is not detected when 0 is set. • 0 to 5 times
NumOfCycleOverErrDetectTimes	Number of Cycle Over Error Detections	Sets the number of cycles until the cycle over error of each cycle is detected. Operates at 5 (default value) when 0 is set. • 1 to 5 times
CycleOverErrorType	Cycle Over Error Selection	Selects an assignment for the over error of each cycle. • 2: Minor Error (MinorError) • 3: Moderate Error (ModerateError)

System Parameter Constant (MotionSystem.PrConst.)

Variable/structure name	Name	Details
OperationCycle[1].NumOfCycleOverWngDetectTimes	Number of Cycle Over Warning Detections	Stores each setting value of the first operation cycle. For details, refer to the following. ☞ Page 522 CYCLE_PARAM.
OperationCycle[1].NumOfCycleOverErrDetectTimes	Number of Cycle Over Error Detections	
OperationCycle[1].CycleOverErrorType	Cycle Over Error Selection	
OperationCycle[2].NumOfCycleOverWngDetectTimes	Number of Cycle Over Warning Detections	Stores each setting value of the second operation cycle. For details, refer to the following. ☞ Page 522 CYCLE_PARAM.
OperationCycle[2].NumOfCycleOverErrDetectTimes	Number of Cycle Over Error Detections	
OperationCycle[2].CycleOverErrorType	Cycle Over Error Selection	
OperationCycle[3].NumOfCycleOverWngDetectTimes	Number of Cycle Over Warning Detections	Stores each setting value of the third operation cycle. For details, refer to the following. ☞ Page 522 CYCLE_PARAM.
OperationCycle[3].NumOfCycleOverErrDetectTimes	Number of Cycle Over Error Detections	
OperationCycle[3].CycleOverErrorType	Cycle Over Error Selection	

Axis parameter constant (AxisName.PrConst.)

Variable/structure name	Name	Details
OperationCycle	Control Cycle Setting	Sets the control operation cycle of the axis. • 0: Automatic setting For a real axis, the same operation cycle as the communication cycle of the device station assigned to the axis is automatically selected. For a virtual axis, the system operates in the first operation cycle. • 1: Operate in the first operation cycle • 2: Operate in the second operation cycle • 3: Operate in the third operation cycle When a setting that does not match the communication cycle of the device is selected on the real axis, Cycle assignment incorrect (axis) (error code: 1B2BH) occurs.

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
OperationCycle	Control Cycle Setting	Stores the control operation cycle of the axis. 0: Axis uninitialized/Control cycle setting out of range 1: Operate in the first operation cycle 2: Operate in the second operation cycle 3: Operate in the third operation cycle

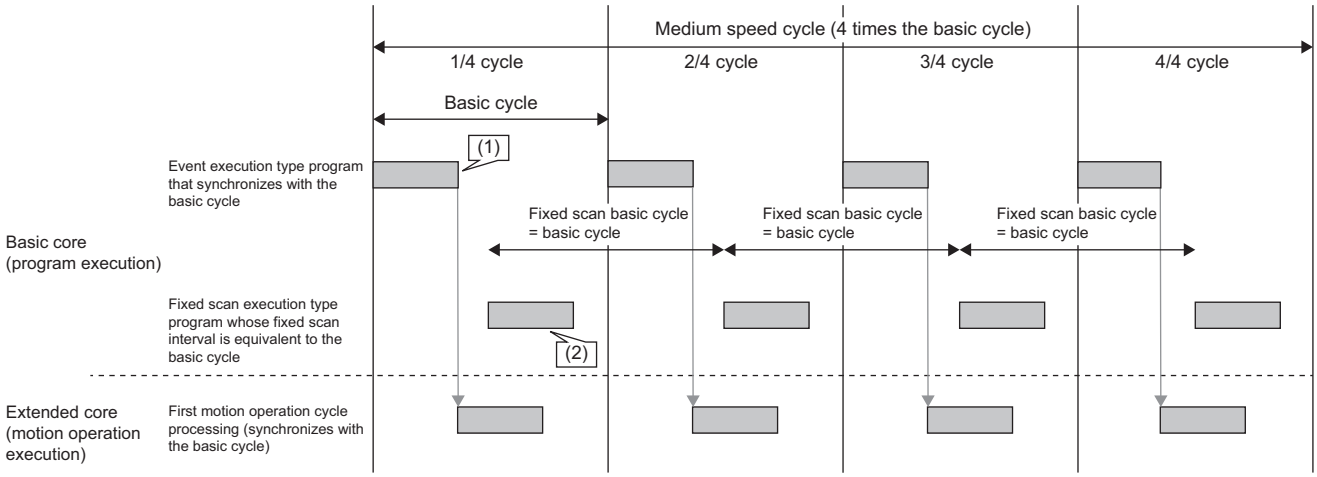
CYCLE_MONI.

Variable/structure name	Name	Details
Cycle	Setting Cycle	Stores the cycle setting of each cycle. • First operation cycle: 125000 to 10000000ns • Second operation cycle: 500000 to 40000000ns • Third operation cycle: 2000000 to 1280000000ns
ProcessingTime	Processing Time	Stores the processing time of each cycle. 0 to 4294967295ns
MaximumProcessingTime	Maximum Processing Time	Stores the maximum processing time of each cycle. 0 to 4294967295ns
CycleOver	Cycle Over	Becomes TRUE when the cycle over of each cycle is detected.

System monitor data (MotionSystem.Md.)

Variable/structure name	Name	Details
OperationCycle[1].Cycle	Setting Cycle	Stores the monitor value of the first operation cycle. For details, refer to the following. ☞ Page 523 CYCLE_MONI.
OperationCycle[1].ProcessingTime	Processing Time	
OperationCycle[1].MaximumProcessingTime	Maximum Processing Time	
OperationCycle[1].CycleOver	Cycle Over	
OperationCycle[2].Cycle	Setting Cycle	Stores the monitor value of the second operation cycle. For details, refer to the following. ☞ Page 523 CYCLE_MONI.
OperationCycle[2].ProcessingTime	Processing Time	
OperationCycle[2].MaximumProcessingTime	Maximum Processing Time	
OperationCycle[2].CycleOver	Cycle Over	
OperationCycle[3].Cycle	Setting Cycle	Stores the monitor value of the third operation cycle. For details, refer to the following. ☞ Page 523 CYCLE_MONI.
OperationCycle[3].ProcessingTime	Processing Time	
OperationCycle[3].MaximumProcessingTime	Maximum Processing Time	
OperationCycle[3].CycleOver	Cycle Over	
MotionService.Cycle*1	Setting Cycle	Stores the monitor value of the motion service processing. For details, refer to the following. ☞ Page 523 CYCLE_MONI.
MotionService.ProcessingTime	Processing Time	
MotionService.MaximumProcessingTime	Maximum Processing Time	
MotionService.CycleOver*2	Cycle Over	

*1 "0" is always stored because the cycle setting does not exist.



*2 FALSE is always set because the cycle over detection is not executed.

25.2 Motion Operation Cycle Setting

By using the motion operation cycle setting, the first, second, and third operation cycles can be set.
The shorter the motion operation cycle, the more accurate and responsive the motion operation becomes. The first motion operation cycle synchronizes with the basic cycle of the network. The second motion operation cycle synchronizes with the medium speed cycle of the network, and the third motion operation cycle synchronizes with the low speed cycle of the network.
For the communication period setting of the network, refer to the following.
☞ Page 287 Basic period setting
☞ Page 293 Multiple period setting
The motion operation cycle can be synchronized with the program execution cycle. When the execution order of a motion operation and a program starts from the beginning of the network communication cycle, with the program always being executed first, followed by the motion operation, this is referred to as a "program synchronous with the motion operation cycle".
The following table lists the combinations of network communication cycles and programs to be synchronized with motion operation cycles.

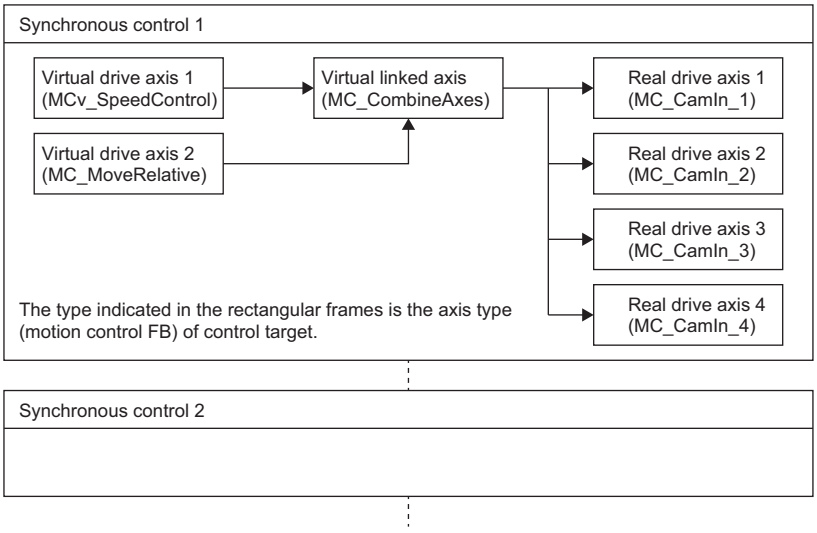
Motion operation cycle	Synchronous network communication cycle	Synchronous program		
		Execution type	Trigger type	Execution cycle
First operation cycle	Basic cycle	Event	Network communication cycle synchronization	Basic cycle
Second operation cycle	Normal-speed cycle			Normal-speed cycle
Third operation cycle	Low-speed cycle			Low-speed cycle

For the event execution type program, refer to the following.
☞ Page 252 Event execution type program
The motion operation cycle and program will not be synchronized in any combinations other than those listed above.
For example, when the basic cycle is 1ms, the event execution type program to be synchronized with the basic cycle will be synchronized with the first motion operation cycle. However, a fixed scan execution type program whose fixed scan interval is 1ms will not be synchronized with the first motion operation cycle even though their cycles match.

(1) Program that is synchronized with the motion operation cycle (the program will always be executed first, followed by the motion operation.)
(2) Program that is not synchronized with the motion operation cycle (the program execution cycle will not be synchronized with the motion operation cycle even though their operation cycles match. In addition, the execution order of the program and motion operation will not be guaranteed.)

A rough standard for the operation cycle settings

The following shows a reference of the operation cycle settings.



■A rough standard for the number of axes and the operation cycle settings when using the positioning control

The rough standard shown below is the one when real drive axes are set as axes groups of two axes each and positioning control is performed repeatedly.

Operation cycle	MXR300-16	MXR300-32	MXR300-64	MXR500-128	MXR500-256
125 [μs]	2 axes			4 axes	
250 [μs]	16 axes	22 axes		26 axes	
500 [μs]	16 axes	32 axes	48 axes	58 axes	
1.0 [ms]	16 axes	32 axes	64 axes	108 axes	
1.5 [ms]	16 axes	32 axes	64 axes	128 axes	140 axes
2.0 [ms]	16 axes	32 axes	64 axes	128 axes	180 axes
3.0 [ms]	16 axes	32 axes	64 axes	128 axes	256 axes
4.0 [ms]	16 axes	32 axes	64 axes	128 axes	256 axes
8.0 [ms]	16 axes	32 axes	64 axes	128 axes	256 axes

■A rough standard for the number of axes and the operation cycle settings when using the synchronous control

A rough standard is shown below when Synchronous control 1 in the following configuration example is one unit, Virtual drive axis 1 and Virtual drive axis 2 are controlled, and four Real drive axes are synchronized. (The number of using axes shown in the table indicates the number of real drive axes in the configuration example.)

Operation cycle	MXR300-16	MXR300-32	MXR300-64	MXR500-128	MXR500-256
125 [μs]	—			4 axes	
250 [μs]	12 axes			20 axes	
500 [μs]	16 axes	32 axes		40 axes	
1.0 [ms]	16 axes	32 axes	60 axes	68 axes	
1.5 [ms]	16 axes	32 axes	64 axes	92 axes	
2.0 [ms]	16 axes	32 axes	64 axes	120 axes	
3.0 [ms]	16 axes	32 axes	64 axes	128 axes	164 axes
4.0 [ms]	16 axes	32 axes	64 axes	128 axes	216 axes
8.0 [ms]	16 axes	32 axes	64 axes	128 axes	256 axes

Point

- Adjust the operation cycle setting depending on the system load status.
- The operation time increases when the motion control FB starts. The increase of operation time can be reduced by changing the start timing.
- Note the following for parameter setting values, and adjust them depending on the system load status.
  (1) As the operation time increases while Cycle Over Warning (event code: 00F08H) is output, set "0" to Number of Cycle Over Warning Detections (MotionSystem.PrConst.OperationCycle[1].NumOfCycleOverWngDetectTimes), so Cycle Over Warning (event code: 00F08H) will not be output.
  (2) The user needs to check the normal operation range of Number of Cycle Over Error Detections (MotionSystem.PrConst.OperationCycle[1].NumOfCycleOverErrDetectTimes), and change values to avoid Cycle over (error code: 1A00H, 3402H).
- If the processing load of a program with a higher priority than the motion operation cycle such as an event execution type program that synchronizes with the basic cycle is high, the operation cycle may increase. Change the communication cycle setting according to the system load status, or reduce the processing load of the event execution type program that synchronizes with the network communication cycle.

25.3 Operation Cycle Assignment

An operation cycle of the axis can be set by Control Cycle Setting (AxisName.PrConst.OperationCycle).
The motion system controls axes in the interval of the specified operation cycle. Values that can be set differ depending on the axis type. For details, refer to the following.
☞ Page 522 Relevant Variables
The control operation cycle upper limit of the axis is 8ms regardless of the axis type. If a cycle longer than 8ms is set, Cycle assignment incorrect (axis) (error code: 1B2BH) occurs. In this case, perform the following.

- Change the control operation cycle of the axis to a shorter operation cycle. (Example: Change the control operation cycle of the axis from the third operation cycle to the second or first operation cycle.)
- Change the basic cycle interval of the network to a shorter cycle.*1
- When the third operation cycle is specified for the control operation cycle of the axis, change the low-speed cycle interval of the network to a shorter cycle.*1

Note that the control operation cycle of the axis cannot be set in 1μs increments. When such a setting is configured, Cycle assignment incorrect (axis) (error code: 1B2BH) occurs. When performing motion control, set "Setting in Units of 1μs" in basic cycle settings for the network to "Not Set". *1

*1 For the network communication cycle setting method, refer to the following.
☞ Page 287 Basic period setting
☞ Page 293 Multiple period setting

25.4 Motion Operation Processing Time Monitor

The processing time of the motion operation and its details can be monitored.

Operation of this function for each system status

○: Available

System status	Operation availability
STOP	○
RUN	○
Moderate error	○
Major error	○

Relevant Variables

The following variables are relevant to the motion operation processing time monitor:

- CYCLE_PARAM.
- System parameter constant (MotionSystem.PrConst.)
- CYCLE_MONI.
- System monitor data (MotionSystem.Md.)

For details, refer to the following.

☞ Page 522 Relevant Variables

Control details

The following contents are controlled by the motion operation processing time monitor.

Operation cycle settings

The first operation cycle setting to third operation cycle setting are stored in the following with a unit of nanosecond [ns].

- MotionSystem.Md.OperationCycle[1].Cycle
- MotionSystem.Md.OperationCycle[2].Cycle
- MotionSystem.Md.OperationCycle[3].Cycle

Operation cycle processing time

The first operation cycle processing time to third operation cycle processing time are stored in the following with a unit of nanosecond [ns]. It includes the time of the processing whose priority is higher than each operation cycle.

- MotionSystem.Md.OperationCycle[1].ProcessingTime
- MotionSystem.Md.OperationCycle[2].ProcessingTime
- MotionSystem.Md.OperationCycle[3].ProcessingTime

Operation cycle maximum processing time

The maximum values of the first operation cycle processing time to third operation cycle processing time are stored in the following.

- MotionSystem.Md.OperationCycle[1].MaximumProcessingTime
- MotionSystem.Md.OperationCycle[2].MaximumProcessingTime
- MotionSystem.Md.OperationCycle[3].MaximumProcessingTime

Motion service processing time

The motion service processing time is stored in Processing Time (MotionSystem.Md.MotionService.ProcessingTime) with a unit of nanosecond [ns]. It includes the task processing time whose priority is higher than the motion service processing.

Motion service maximum processing time

The maximum value of the motion service processing time is stored in Maximum Processing Time (MotionSystem.Md.MotionService.MaximumProcessingTime).

Operation cycle over check

If the processing of each operation cycle has not been completed by the start of the next operation cycle processing, Cycle Over (MotionSystem.Md.OperationCycle[1..3].CycleOver) of the operation cycle will be TRUE. If an operation cycle over is detected, the new operation cycle processing will not be executed within the current cycle and will be executed at the start of the next operation cycle processing.

To reset the operation cycle over, set Cycle Over (MotionSystem.Md.OperationCycle[1..3].CycleOver) to FALSE by using a program or other means. If an operation cycle over is detected again after the system is reset, Cycle Over (MotionSystem.Md.OperationCycle[1..3].CycleOver) of the operation cycle will be TRUE.

Point

At the start of operation cycle processing, if an operation cycle over has already occurred for an operation cycle with the shorter period, a cycle over will also occur for the operation cycle with the longer period. In this case, the operation cycle with the longer period will not be executed.

If an operation cycle over is detected, take one of the following actions.

- Adjust the operation cycle setting (network communication period setting) to a larger value. Set the value of the operation cycle by referring to the value of each label of the operation cycle or the value of the maximum processing time of each operation cycle displayed on the axis monitor of the engineering tool. For information on how to adjust the cycle settings, refer to the following.

☞ Page 287 Setting method

- Reduce the processing load that has caused the cycle over. Changing the axis control operation cycle can distribute the processing load. (Example: Change the control operation cycle of the axis from the first operation cycle to the second operation cycle.)

Cycle over warning/error detection

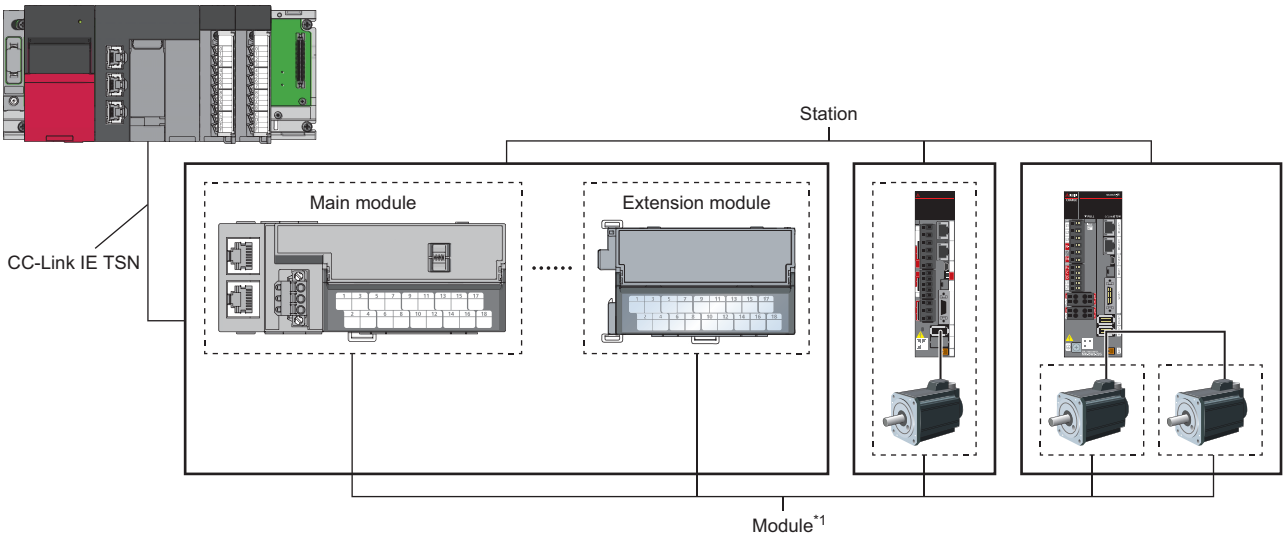
If the number of consecutive cycle over for each cycle has reached the set number of cycle over warning or error detections, a cycle over warning or error will be detected. The warning will not be detected if the number of cycle over warning detections is set to a value equal to or greater than the number of cycle over error detections. The warning will also not be detected if the number of cycle over warning detections is set to zero.

For the cycle over error type of each cycle, either a minor error or moderate error can be selected. When a cycle over error occurs, the operation stops according to the process selected by Stop Selection at Stop Cause Occurrence (AxisName.Pr.StopMode_General) or Stop Selection at All Axes Stop Cause Occurrence (MotionSystem.Pr.StopMode_All).

Point

- When a moderate error occurs due to WDT error (error code: 2500H, 2501H) detection, the operation may fail to perform deceleration stop and result in immediate stop when WDT error (error code: 2500H, 2501H) is detected depending on the system status.
- When a minor error is selected for the cycle over error type, the operation may continue until a WDT error (error code: 2500H, 2501H) is detected. Ensure the safety even in such a case.

Precautions



When a disabling interrupt (DI) instruction is used, a cycle over error may occur.

For details on the DI instruction, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

25.5 Specifications of Modules on CC-Link IE TSN Configuration Controlled by the Motion System

The motion system can control modules on the following CC-Link IE TSN configuration.

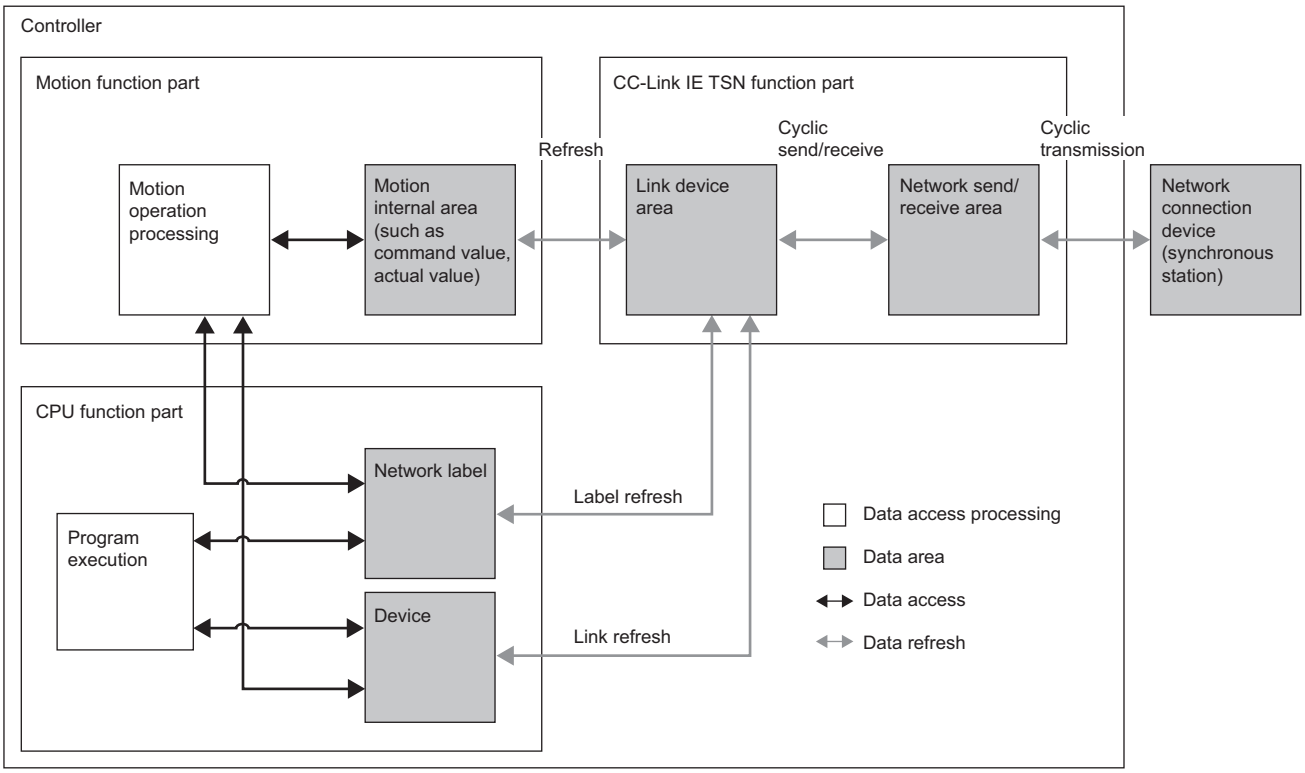
*1 The first axis of a multi-axis amplifier is considered the main module and the second and subsequent axes are considered extension modules.

The motion system controls the main module and extension module that meet any of the following conditions when the motion system starts up.

- When a main module or extension module whose IP address and multidrop number are set as the station address of the real drive axis or real encoder axis
- When an MC_TRIGGER_REF type or MC_OUTPUT_REF type global label refers to the refresh target (network label or device) of cyclic data of a main module or extension module
- When an MC_TRIGGER_REF type global label refers to a CANopen object of a main module or extension module
- Modules with an MC_OUTPUT_REF type global label that refers to input (X) and output (Y) that are already set for the synchronization timing control mode of the module
- Modules that refer to the clutch signal setting of the advanced synchronization control function

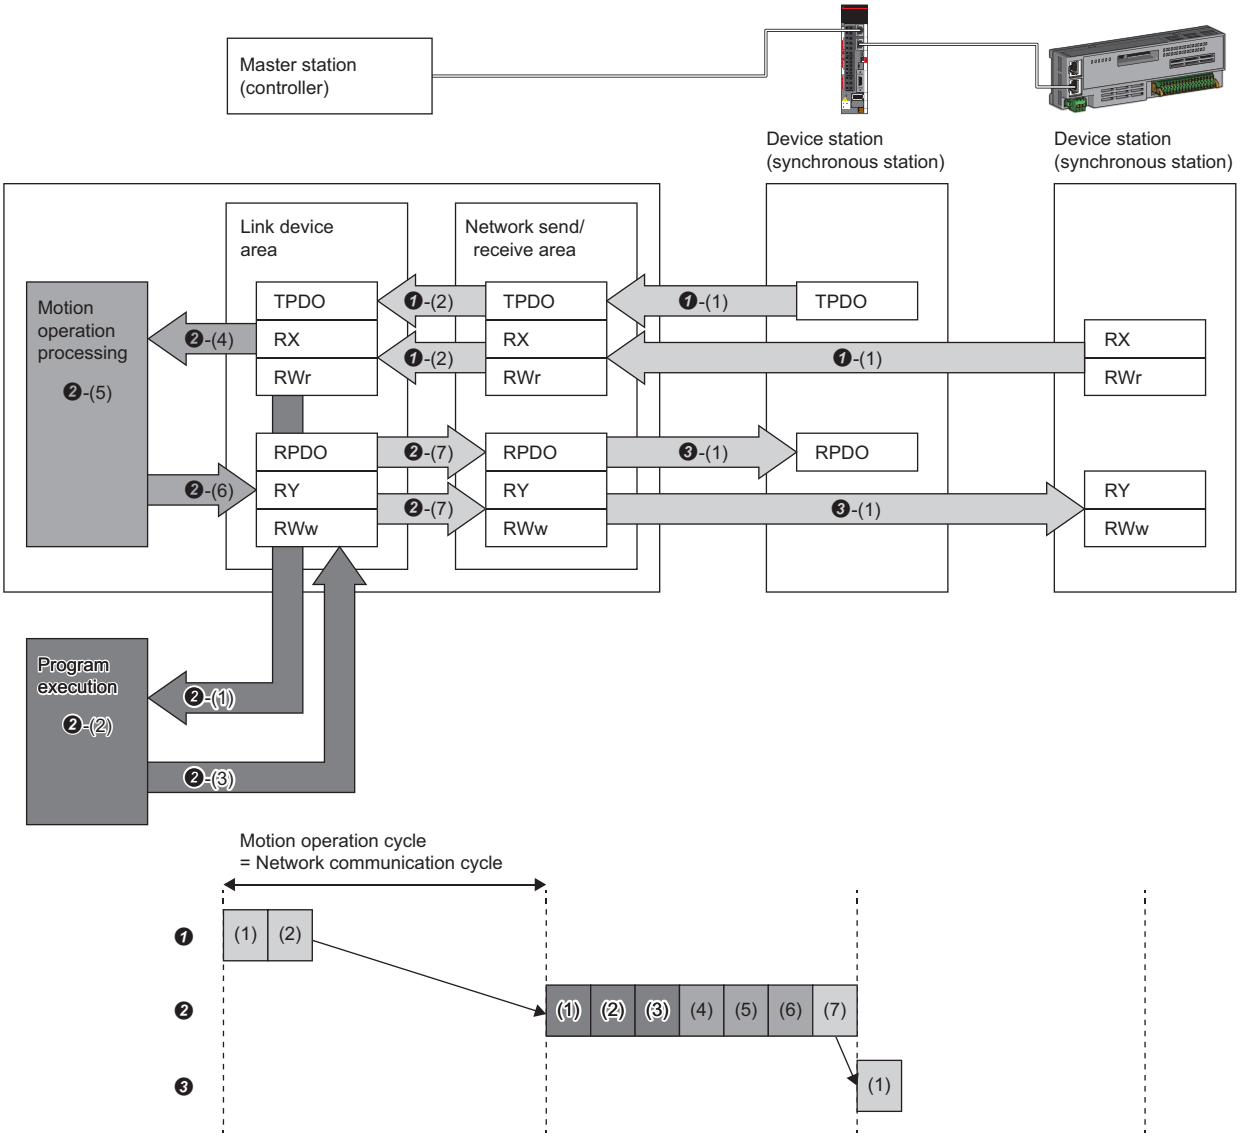
Control details

Be sure to set the network synchronous communication setting of the module controlled by the motion system to "Synchronous".



When the network synchronous communication setting is set to "Asynchronous" when the motion system starts up, Synchronization setting combination error (at system startup) (error code: 3407H) occurs.

Refer to each function for the operation when the axis parameters have been changed by starting the FB or performing online program change or if any of the global labels listed below has been added or deleted after the motion system starts up and the network synchronous communication of the module controlled by the motion system is set to "Asynchronous".



- MC_TRIGGER_REF type
- MC_OUTPUT_REF type
- SIGNAL_SELECT type set for the clutch signal setting of the advanced synchronization control

25.6 Send/Receive Data Refresh of Network Connected Devices

The following figure shows the relation of data areas and the refresh.

The execution timing of the data area refresh described above and data access processing is shown below.
For the connected device, it takes three cycles in the unit of motion operation cycle to receive a feedback to the data sent from the connected device.

❶-(1) Cyclic transmission
❶-(2) Cyclic receive processing
❷-(1) Input refresh of synchronous station
❷-(2) Program execution
❷-(3) Output refresh of synchronous station
❷-(4) Input processing of motion operation
❷-(5) Operation processing of motion operation
❷-(6) Output processing of motion operation
❷-(7) Cyclic send processing
❸-(1) Cyclic transmission

When multiple operation cycles coexist, the processing above is performed during each cycle (basic, medium speed, low speed). For details, refer to the following.

☞ Page 535 Operation Cycle Coexistence

When Watchdog counter error (error code: 1A40H) occurs, perform an axis error reset for the relevant axis and restart the transfer of receive data to the device/label.

For details on either a network label refresh or device link refresh, refer to the following.

☞ Page 234 Refresh mode

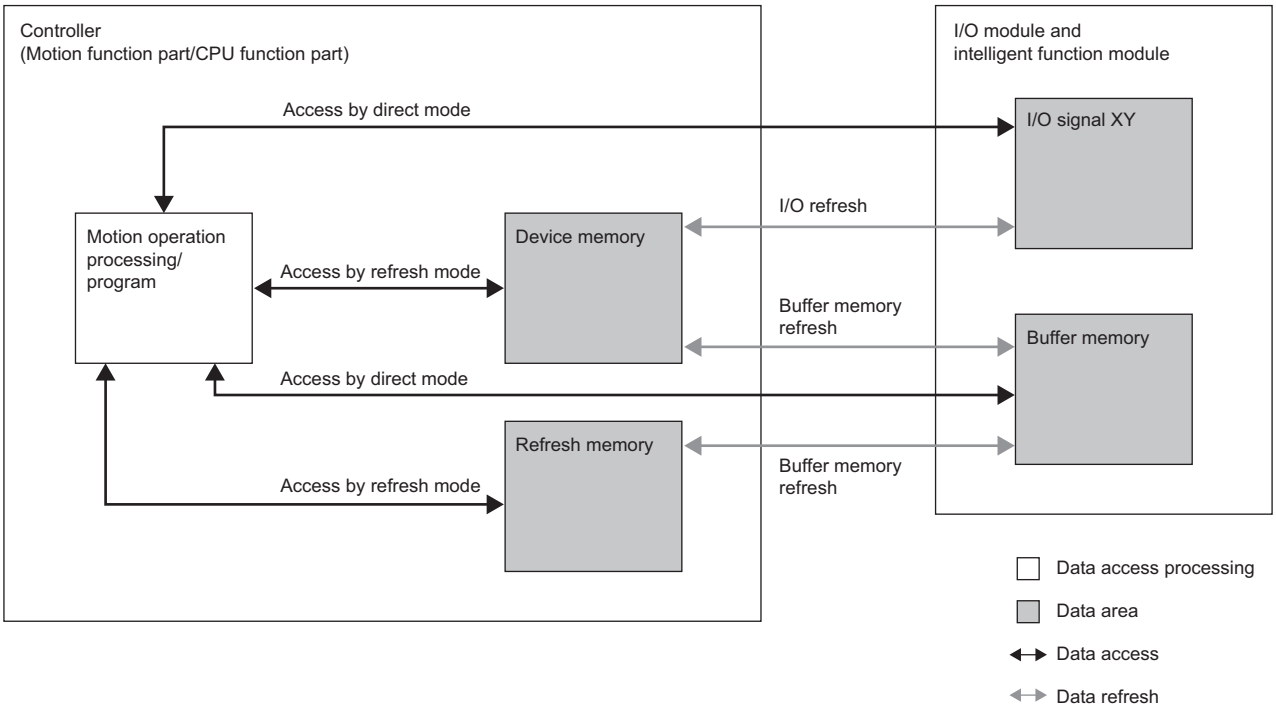
For details on either watchdog counter or the procedure to restart the transfer of receive data to the device/label, refer to the following.

☞ Page 240 Checking received data using the watchdog counter

Point

- When the same network label or link refresh target device values have been rewritten between the motion operation and program that are synchronous to the same network communication cycle, writing by the motion operation takes priority. (Regarding data sent from the motion system, values written by the program are rewritten by the motion operation.) For data to be sent from the motion system, refer to the following.

☞ Page 472 Object data list



- When the same network label or link refresh target device values have been rewritten between the motion operation and program that are not synchronous to the same network communication cycle, whether the writing by the motion operation or by the program is reflected will be undefined. (The writing to be reflected depends on the timing of writing.)
- If the value in the link device area is rewritten by the motion operation, the same network label and link refresh target device will not be updated.

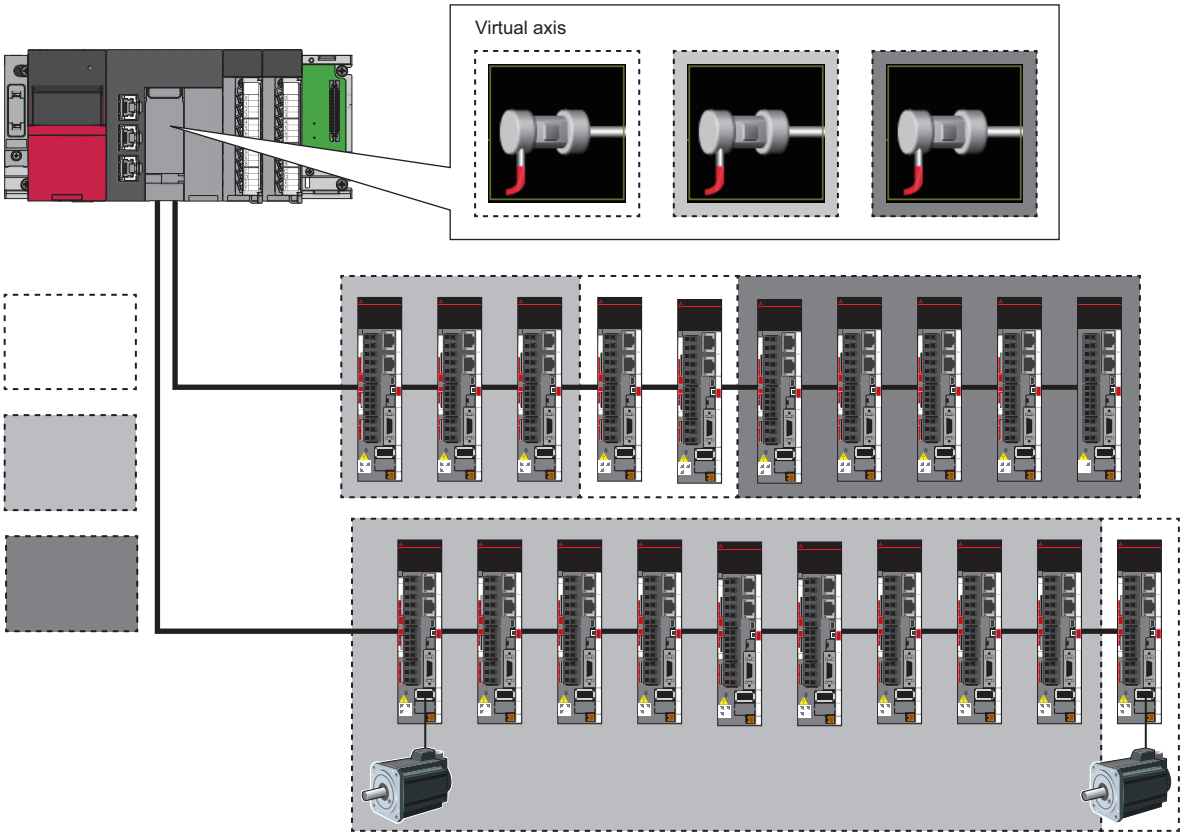
Example 1: If the RWw0 network label is Label0, the rewritten RWw0 value is not reflected in Label0.

Example 2: If the link refresh target device of RWw0 is W0, the rewritten RWw0 value is not reflected in W0.

25.7 Send/Receive Data Refresh of I/O Modules and Intelligent Function Modules

The following figure shows the relation of data areas that communicate between the I/O modules, intelligent function modules, and motion function part and their refresh.

The execution timing of the data area refresh described above and data access processing differs depending on the access method (refresh mode or direct mode).

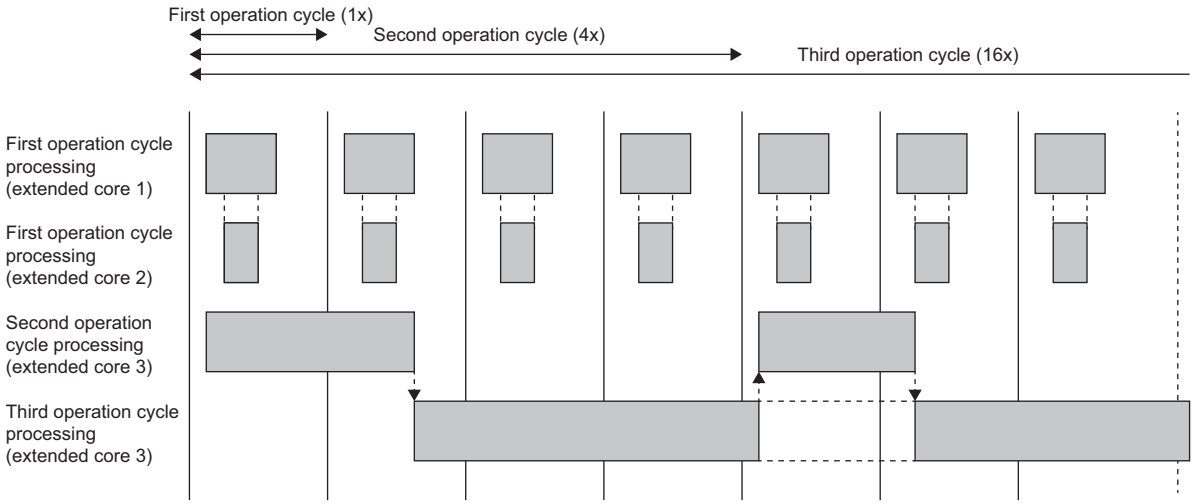


For details on the processing execution timing for each access method, refer to the following.

☞ Page 1236 Link Refresh

☞ Page 1241 Direct Access to Link Devices

25.8 Operation Cycle Coexistence



This function is used to divide and execute operation cycle processing of the motion system in different cycles (maximum of three operation cycles).
A system with many controlled axes can be controlled in divided manner by operating a specific axis at a fast operation cycle and operating other axes at a low speed operation cycle.

Control details

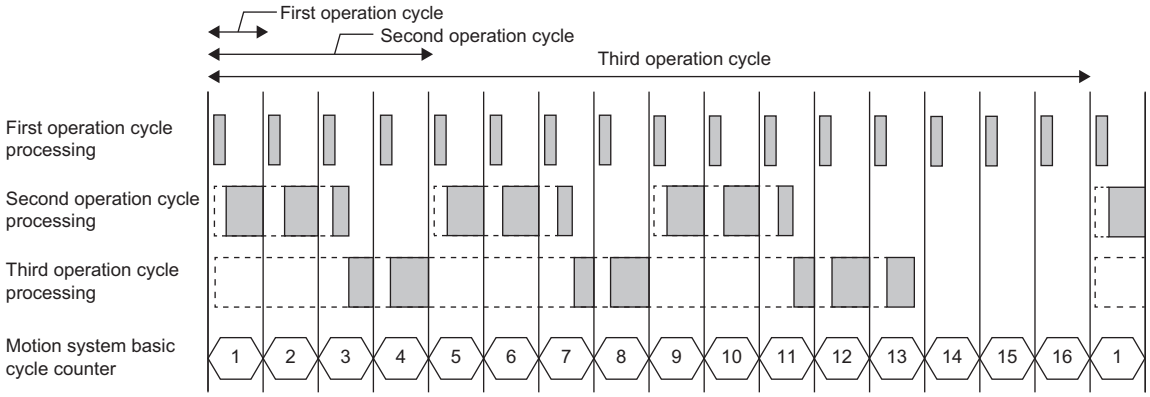
Priority has been determined regarding processing inside the motion system. When the execution conditions for high-priority operation cycle processing are met, such processing is executed preferentially than low-priority operation cycle processing. The first operation cycle has higher priority than the second operation cycle and the second operation cycle has higher priority than the third operation cycle.

The following figure shows the processing timing inside the motion system when the first operation cycle is set to the basic cycle of the network, the second operation cycle is set to the medium speed cycle of the network (4 times the basic cycle), and the third operation cycle is set to the low speed cycle of the network (16 times the basic cycle).

- Among the first operation cycle processing, processes that can be executed in parallel are executed using two extension cores. Also, the first operation cycle processing is executed in parallel with the second and third operation cycle processing.
- The third operation cycle processing is executed after the second operation cycle processing is completed. If the execution conditions for the second operation cycle processing are met while the third operation cycle processing is executed, the third operation cycle is suspended and the second operation cycle processing is executed.

Point

Low-priority operation cycle processing is executed during the vacant time of high-priority operation cycle processing. For this reason, if the high-priority operation cycle processing load increases, sufficient time may not be secured for executing low-priority operation cycle processing. If Cycle over (error code: 1A00H, 3402H) occurs, correct the axis assignment to operation cycles, communication period setting of the network, and program details.



For a rough standard for the number of axes that can operate in each operation cycle, refer to the following.

☞ Page 525 A rough standard for the operation cycle settings

■Motion system basic cycle counter

The system basic cycle counter (System.Md.SystemBaseCycle_Counter) counts up by one at basic cycle intervals of the network, and returns to one when the cycle is greater than the least common multiple of each motion operation cycle. This counter can be used to check the timing for executing each motion operation cycle processing.

The following figure shows the processing timing inside the motion system when the first operation cycle is set to the basic cycle of the network, the second operation cycle is set to the normal speed cycle of the network (4 times the basic cycle), and the third operation cycle is set to the low speed cycle of the network (16 times the basic cycle).

■Control operation cycle synchronization

If the control operation cycle is different between input and output in the following function, synchronize input with the control operation cycle of output using Synchronize Control Operation Cycle (MCv_SyncOperationCycles) before control.

- Single axis synchronous control FB

For details on Synchronize Control Operation Cycle (MCv_SyncOperationCycles), refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

For details on touch probe control (trigger input signal detection and latching), refer to the following.

☞ Page 1166 TOUCH PROBE

Program example

■Overview

The following example shows a program that executes the synchronous control on axes with different control cycles by using Synchronize Control Operation Cycle (MCv_SyncOperationCycles).

In this program example, MC_GearIn is started while Axis0001 to be controlled in the first operation cycle is regarded as the master axis and Axis0002 to be controlled in the second operation cycle is regarded as the slave axis.

A program that executes servo ON for the MR-J5-G is omitted.

■Setting

• CC-Link IE TSN configuration

Station No.	Model name	IP address	Network synchronous communication setting	Communication period setting
1	MR-J5-G	192.168.4.1	Synchronous	Basic period
2	MR-J5-G	192.168.4.2	Synchronous	Normal-speed

• Axis

Axis No.	Label name	Station address setting	Axis type	Control cycle setting
1	Axis0001	192.168.4.1	Real drive axis	Operates in the first operation cycle.
2	Axis0002	192.168.4.2	Real drive axis	Operates in the second operation cycle.

• Labels used

Label name	Data type	Comment
bSyncStart	Bit	Synchronous control start
bMCGearInExecute	Bit	Gear operation start
MCv_SyncOperationCycles _1	MCv_SyncOperationCycles	Control operation cycle synchronization FB
MC_GearIn_1	MC_GearIn	Gear operation start FB

■Program

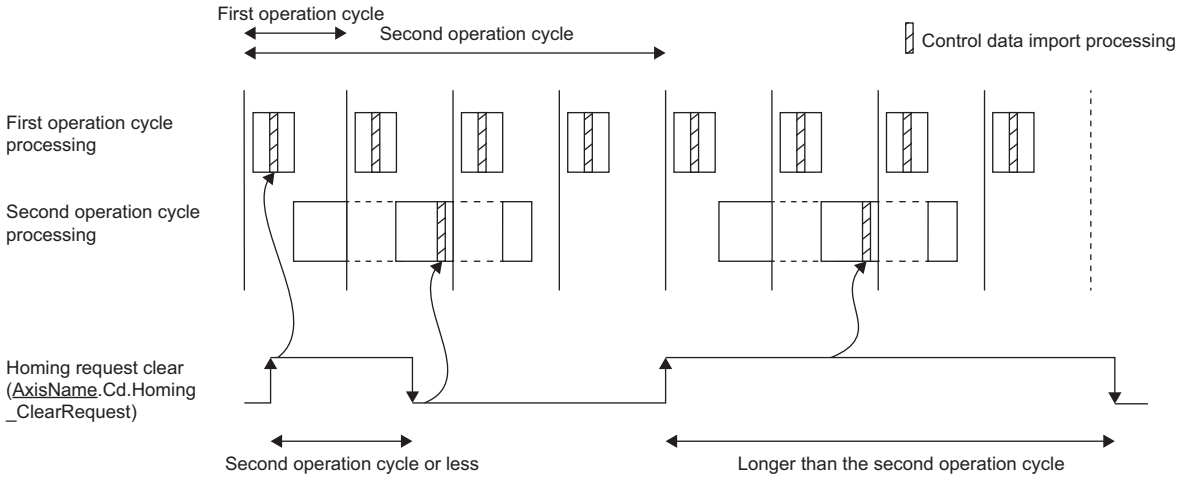
ST programs are shown below.

```
SET( MCv_SyncOperationCycles_1.Enabled , bMCGearInExecute );
//-----Control operation cycle synchronization-----
MCv_SyncOperationCycles_1(
    Axis:= Axis0001.AxisRef ,
//  ValueSource:= ?TARGET_REF? ,//Omitted
    Enable:= bSyncStart,
    OperationCycle:= 2 ,//2: Second operation cycle
    Options:= 0
);

//-----Gear operation start-----
MC_GearIn_1(
    Master:= Axis0001.AxisRef ,
    Slave:= Axis0002.AxisRef ,
    Execute:= bMCGearInExecute ,
    ContinuousUpdate:= TRUE ,
    RatioNumerator:= 1 ,
    RatioDenominator:= 1 ,
    MasterValueSource:= MC_SOURCE__mcSetValue ,
    Acceleration:= 1000.0 ,
    Deceleration:= 1000.0 ,
    Jerk:= 0.0 ,
    BufferMode:= MC_BUFFER_MODE__mcAborting ,
    Options:= 0
);
```

Precautions

■Timing of importation of the control data of the axis and axes group and external input signals

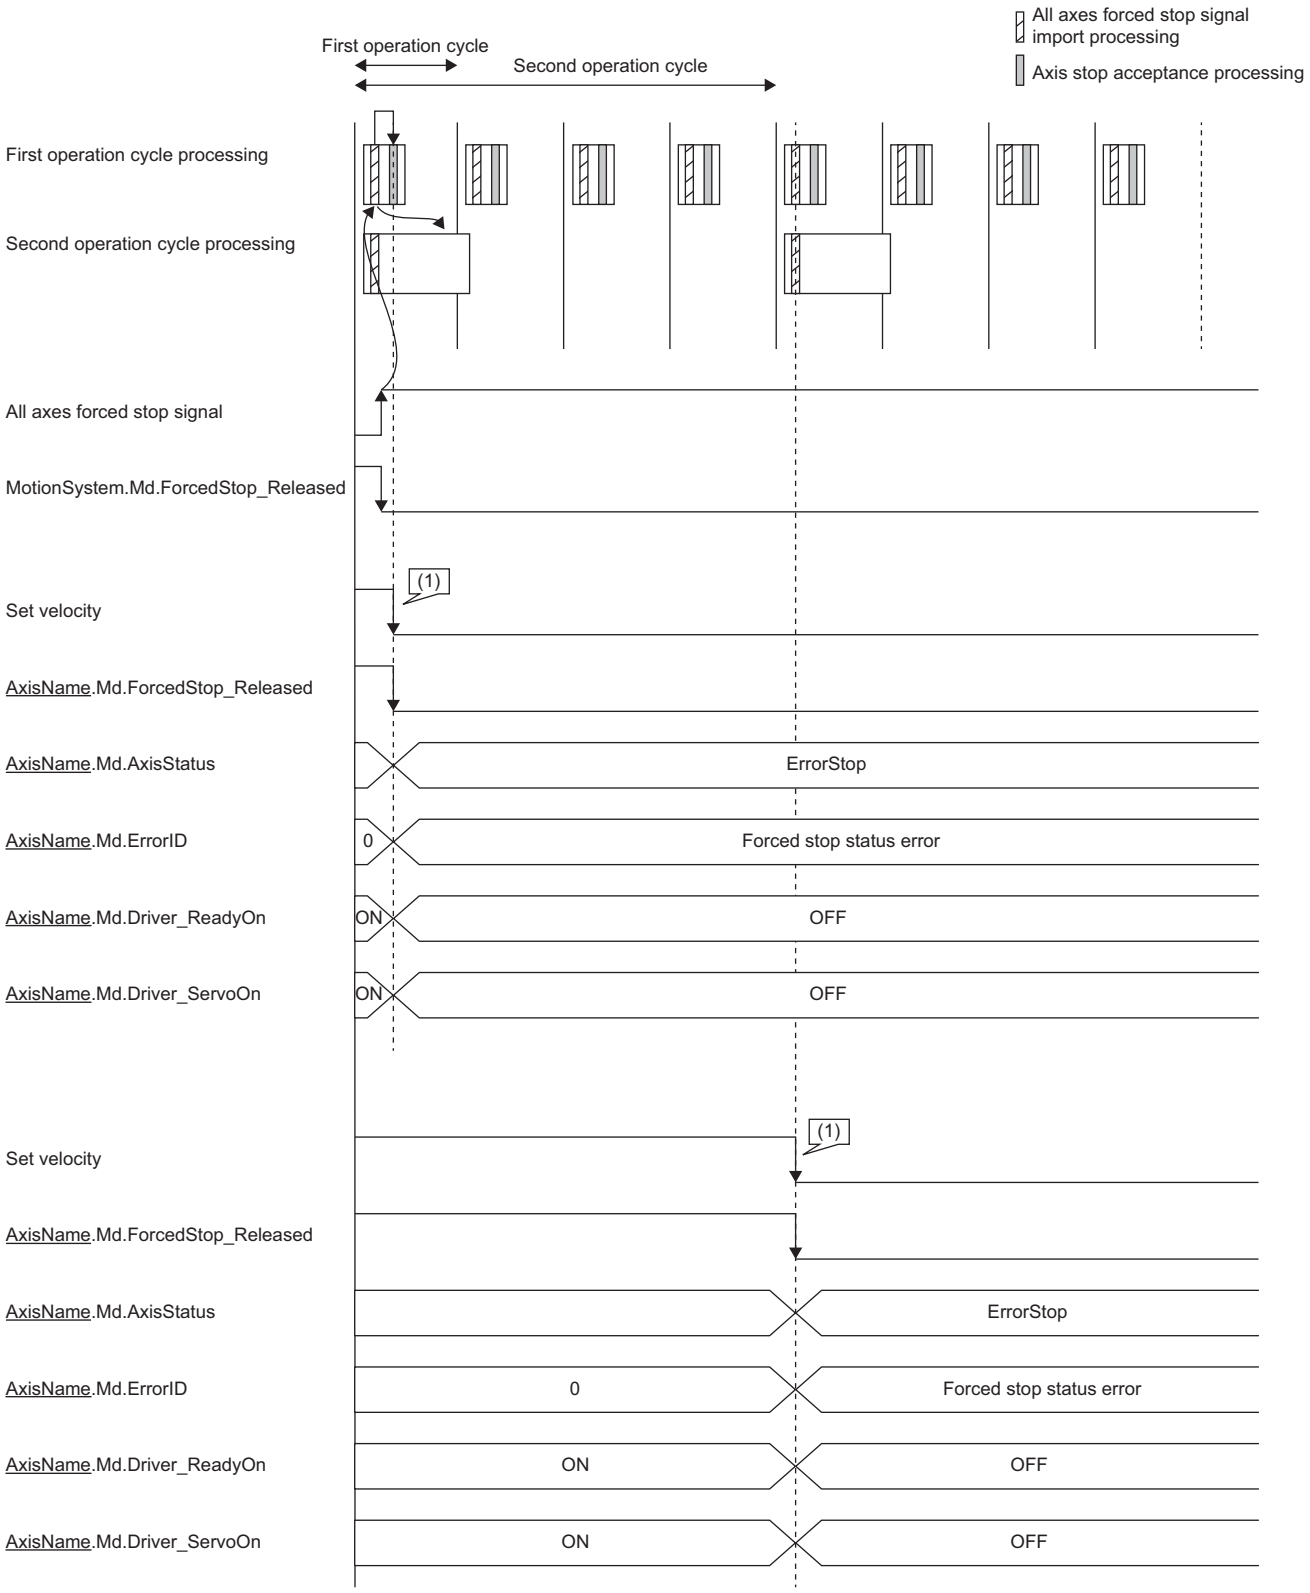


Importation of the control data of the axis and axes group and the following external input signals is performed at the control operation cycle of the axis. Therefore, if control data or external input signals are updated at an interval equal to or shorter than the control operation cycle, the update may not be detected.

Be sure that the interval to update the control data of the axis and external input signals is longer than the control operation cycle of the relevant axis.

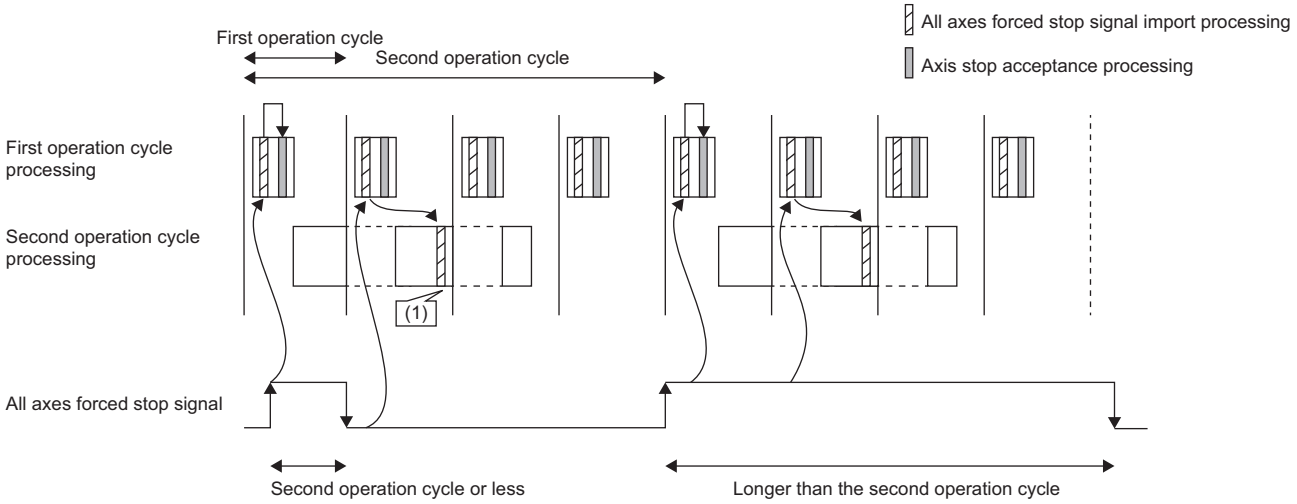
- Upper Limit Signal (AxisName.PrConst.HwStrokeLimit_FlsSignal)
- Lower Limit Signal (AxisName.PrConst.HwStrokeLimit_RlsSignal)
- Forced Stop Signal (AxisName.Pr.ForcedStop_Signal)
- Stop Signal (AxisName.Pr.StopSignal)
- Counter Disabling Signal (AxisName.PrConst.Encoder_CounterDisableSignal)

Ex.



When setting Homing Request to FALSE by using Homing Request Clear (AxisName.Cd.Homing_ClearRequest)

■Timing of importation of the all axes forced stop signal



Importation of the all axes forced stop signal is performed in the first operation cycle and the stop processing is performed at the operation cycle of the axis.

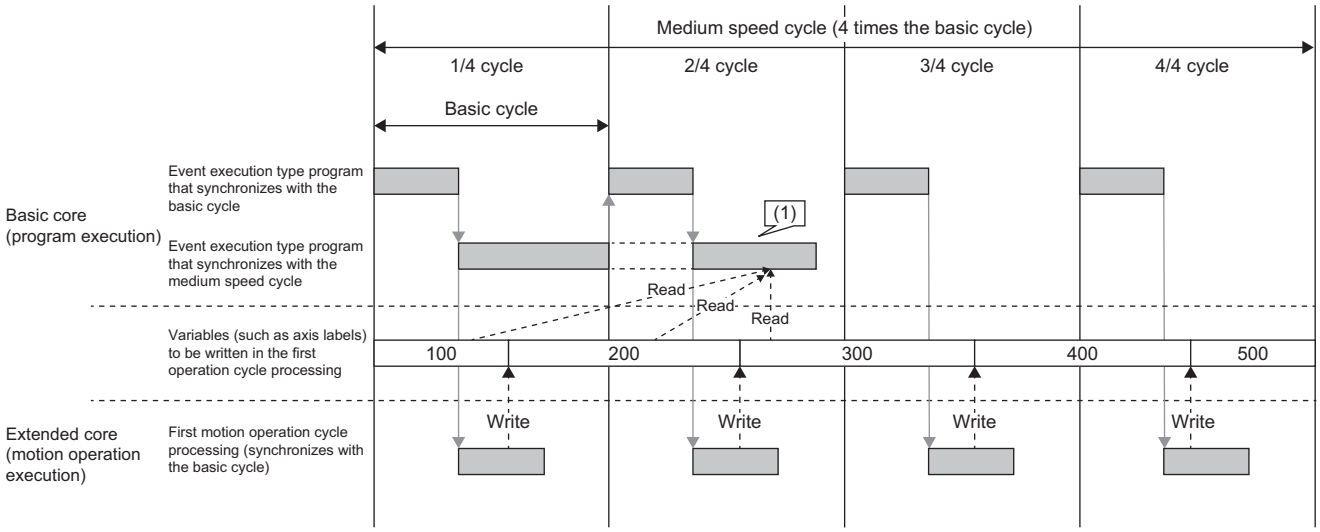
Therefore, the stop processing of the axis assigned to the second or third operation cycle may be delayed by the second or third operation cycle at the most as compared to the axis assigned to the first operation cycle.

(1) Immediate stop

If the all axes forced stop signal is updated at an interval equal to or shorter than the second and third operation cycles, the update may not be detected. Be sure that the interval to update the all axes forced stop signal is longer than the second and third operation cycles.

(1) The stop processing is not executed because the input of all the axes forced stop signal cannot be obtained.

25.9 Precautions for Programming



The user program and motion operation are executed in parallel on the multi-core. When a variable to be used is accessed by the motion operation from a user program at an execution cycle different from the motion operation cycle, the update timing for the variable may become undefined. When the update timing for the variable is important, access the variable from a program synchronous with the motion operation cycle.

For details on the program synchronous with the motion operation cycle, refer to the following.

☞ Page 524 Motion Operation Cycle Setting

Ex.

If the update timing for the variable is undefined

(1) Since the update timing for the variable is undefined when viewed from the program, a value other than the latest value (300) may be read.

Examples where the motion operation cycle is asynchronous with the user program execution cycle are described below.

- Access to a label of an axis/axes group to be controlled at the first operation cycle from a program other than an event execution type program that synchronizes with the basic cycle
- Access to a label of an axis/axes group to be controlled at the second operation cycle from a program other than an event execution type program that synchronizes with the normal speed cycle
- Access to a label of an axis/axes group to be controlled at the third operation cycle from a program other than an event execution type program that synchronizes with the low speed cycle
- Access to a label of an axis/axes group to be controlled at the first operation cycle from a fixed scan execution type program whose fixed scan interval matches that of the first operation cycle (also applies to second and third operation cycles)
- Access to a label of a motion control FB from a program whose execution type and execution cycle are different from those of the motion control FB source program

26 START AND STOP

26.1 Start

This function starts motion control.
This section describes how to start an axis of the motion system.
In the motion system, motion control can be executed by executing the motion control FB from programs.
Starting the motion control by executing the motion FB with Axis Status (AxisName.Md.AxisStatus) set to "4: Standby (Standstill)" or Axes Group Status (AxesGroupName.Md.GroupStatus) set to "4: Standby (GroupStandby)" is called "start" of the axis.
FBs have Execution command (Execute) type and Enable (Enable) type, and these are started at the rising edge of Execution command (Execute) or Enable (Enable) which are input variables of the motion control FB.

Operation of this function for each system status

○: Available, ×: Not available

System status	Operation availability
STOP	×
RUN	○
Moderate error	×
Major error	×

Relevant variables

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
AxisStatus	Axis Status	Displays the axis status. • 0: Axis disabled (Disabled) • 1: Stopping on error (ErrorStop) • 2: Decelerating to stop (Stopping) • 3: During homing (Homing) • 4: Standby (Standstill) • 5: During positioning operation (DiscreteMotion) • 6: During continuous operation (ContinuousMotion) • 7: During synchronous operation (SynchronizedMotion)
UseInGroup	Using Axes Group	Displays whether the axis is being used in the axis group or not. • FALSE: Not used • TRUE: Used
Homing_Request	Homing Request	Displays whether homing is required or not. Becomes FALSE when the homing is completed. • FALSE: No homing request • TRUE: Homing request
HwStrokeLimit_FlsStatus	Upper Limit Signal Status	Displays the detection status of the upper limit signal (FLS). • FALSE: Detecting the upper limit signal (FLS) • TRUE: Not detecting the upper limit signal (FLS)
HwStrokeLimit_RlsStatus	Lower Limit Signal Status	Displays the detection status of the lower limit signal (RLS). • FALSE: Detecting the lower limit signal (RLS) • TRUE: Not detecting the lower limit signal (RLS)
ForcedStop_Released	Forced Stop Cancelling	Displays the forced stop cancel status. • FALSE: Forced stop • TRUE: Forced stop release
StopStatus	Stop Status	Displays the input status of the stop signal (STOP). • FALSE: Stop processing released • TRUE: During stop processing

Axes group monitor data (AxesGroupName.Md.)

Variable/structure name	Name	Details
GroupStatus	Axes Group Status	Displays the axes group status • 0: Axes group disabled (GroupDisabled) • 1: Stopping on error (GroupErrorStop) • 2: Decelerating to stop (GroupStopping) • 4: Standby (GroupStandby) • 5: Operating (GroupMoving)

System control data (MotionSystem.Cd.)

Variable/structure name	Name	Details
SequenceReady	PLC READY	Checks that the status of the CPU function part is normal and displays the signal status to be notified to the motion function part. • FALSE: PLC READY OFF • TRUE: PLC READY ON

■Conditions of TRUE/FALSE status

Conditions where PLC READY (MotionSystem.Cd.SequenceReady) becomes TRUE/FALSE are shown below.

Programmable controller ready interlock selection (MotionSystem.PrConst.SequenceReadyInterlock)	Condition	PLC Ready (MotionSystem.Cd.SequenceReady)
TRUE	While the synchronization flag [X21] was on, the status of the CPU function part changed from STOP to PAUSE/RUN.	TRUE
	While the synchronization flag [X21] was on, the status of the CPU function part changed from initialization complete to PAUSE/RUN.	
	While the status of the CPU function part was PAUSE/RUN, the synchronization flag [X21] changed from off to on.	
FALSE	While the synchronization flag [X21] was on and also the status of the CPU function part was PAUSE/RUN, PLC READY [Y20] changed from off to on.	
	While the synchronization flag [X21] was on and also PLC READY [Y20] was on, the status of the CPU function part changed from STOP to PAUSE/RUN.	
	While the status of the CPU function part was PAUSE/RUN and also PLC READY [Y20] was on, the synchronization flag [X21] changed from off to on.	
TRUE	The status of the CPU function part changed from PAUSE/RUN to STOP.	FALSE
	The synchronization flag [X21] was turned off.	
FALSE	The status of the CPU function part changed from PAUSE/RUN to STOP.	
	PLC READY [Y20] was turned off.	
	The synchronization flag [X21] was turned off.	

System Monitor Data (MotionSystem.Md.)

Variable/structure name	Name	Details
Ready	Ready	Displays the on/off status of built-in Motion Ready [X20]. • FALSE: Off (Not READY) • TRUE: On (READY)
Sync	Synchronization flag	Displays the on/off status of the synchronization flag [X21]. • FALSE: Off (Module access disabled) • TRUE: On (Module access enabled)

Starting conditions

To start the control, the following conditions must be satisfied.
The necessary conditions must be incorporated in the program so that the axis is not started when the conditions are not satisfied.
Starting conditions of the axis are mainly controlled by the state transition and the signal state of the axis and axes group.

Starting conditions for motion FB of the axis

■State transition

Name	State	Variable name
Axis Status	4: Standby (Standstill)	AxisName.Md.AxisStatus

■Signal state

Signal name		Signal state		Variable name
I/O signal	PLC READY [Y20]*1	On	RUN	MotionSystem.Cd.SequenceReady
	Built-in Motion Ready [X20]	On	Built-in motion ready	MotionSystem.Md.Ready
	Synchronization flag [X21]	On	Module access enabled	MotionSystem.Md.Sync
	Using Axes Group	FALSE	Not used	AxisName.Md.UseInGroup
	Homing Request	FALSE	Homing request FALSE	AxisName.Md.Homing_Request
External signal	Forced Stop Cancelling	TRUE	Emergency stop input FALSE (Forced stop cancel)	AxisName.Md.ForcedStop_Released
	Upper Limit Signal Status	FALSE	Within the upper limit range	AxisName.Md.HwStrokeLimit_FlsStatus
	Lower Limit Signal Status	FALSE	Within the lower limit range	AxisName.Md.HwStrokeLimit_RlsStatus
	Stop Status	FALSE	Stop signal (STOP) FALSE	AxisName.Md.StopStatus

*1 If Programmable controller ready interlock selection (MotionSystem.PrConst.SequenceReadyInterlock) is TRUE (default), PLC READY [Y20] is not included in the starting conditions.

Starting conditions for motion FB of the axes group

■State transition

Name	State	Variable name
Axis Status	4: Standby (Standstill)	AxisName.Md.AxisStatus
Axes Group Status	4: Standby (GroupStandby)	AxesGroupName.Md.GroupStatus

■Signal state

Signal name		Signal state		Variable name
I/O signal	PLC READY [Y20]*1	On	RUN	MotionSystem.Cd.SequenceReady
	Built-in Motion Ready [X20]	On	Built-in motion ready	MotionSystem.Md.Ready
	Synchronization flag [X21]	On	Module access enabled	MotionSystem.Md.Sync
	Homing Request	FALSE	Homing request FALSE	AxisName.Md.Homing_Request
External signal	Forced Stop Cancelling	TRUE	Emergency stop input FALSE (Forced stop cancel)	AxisName.Md.ForcedStop_Released
	Upper Limit Signal Status	FALSE	Within the upper limit range	AxisName.Md.HwStrokeLimit_FlsStatus
	Lower Limit Signal Status	FALSE	Within the lower limit range	AxisName.Md.HwStrokeLimit_RlsStatus
	Stop Status	FALSE	Stop signal (STOP) FALSE	AxisName.Md.StopStatus

*1 If Programmable controller ready interlock selection (MotionSystem.PrConst.SequenceReadyInterlock) is TRUE (default), PLC READY [Y20] is not included in the starting conditions.

26.2 Retrigger/Continuous Update

This function changes the control of the on-going FB with a retrigger/continuous update.
With a retrigger/continuous update of the FB, input variables can be imported again to the on-going FB instance without interrupting operation.
The following methods can be used to change the control of the on-going FB.

- Retrigger (Inputting Execution command (Execute) again)
- Continuous update (ContinuousUpdate)

The fetch cycle of each input variable depends on the longest cycle in the following lists.

- Execution cycle of POU (abbreviation for Program Organization Unit) that calls the FB
- Operation cycle

To change input variables when Execute command (Execute) becomes FALSE to TRUE and when Continuous update (ContinuousUpdate) becomes TRUE, be sure to secure time equal to or longer than the cycle.
Also, when a retrigger/continuous update is performed to an instruction being buffered by multiple start of the motion control FB, the change will be reflected at the FB switching.

Point

- A retrigger/continuous update which is immediately after execution and immediately before termination of the FB may be ignored.
  · Immediately after execution: While Analyzing (AxisName.Md.Analyzing) is TRUE
  · Immediately before termination: Immediately before Execution Completed (Done) becomes TRUE
- Even if a retrigger/continuous update is performed to an instruction being buffered, it may affect the control in operation.

Retrigger

In an FB whose start condition is Execution command (Execute), a retrigger can be executed by the re-rising edge of Execution command (Execute).
For input variables that can be changed by a retrigger, refer to the specifications of each FB.

Continuous update

If Continuous update (ContinuousUpdate) is TRUE when Execute command (Execute) changes FALSE to TRUE, input variables will be continuously imported.
For input variables that can be imported, refer to the specifications of each FB.

26.3 Multiple Start (Buffer Mode)

Multiple motion control FBs can be executed continuously without stopping by executing the motion FB of another instance to the axis and the axes group that are executing the motion control FB.

Point

- To execute the motion control FB with the axis and the axes group stop status ("4: Standby (Standstill)" or "4: Standby (GroupStandby)") is called "start". For details, refer to the following.
  ☞ Page 543 Start
- When Axis Status (AxisName.Md.AxisStatus) and Axes Group Status (AxesGroupName.Md.GroupStatus) are as follows, to execute the motion FB of another instance is called "multiple start".
  [Axes Status (AxisName.Md.AxisStatus) that can be multiple started]
  · 3: During homing (Homing) (Only MC_Stop (Forced Stop))
  · 5: During positioning operation (DiscreteMotion)
  · 6: During continuous operation (ContinuousMotion)
  · 7: During synchronous operation (SynchronizedMotion)
  [Axes Group Status (AxesGroupName.Md.GroupStatus) that can be multiple started]
  · 5: In Operation (GroupMoving)
- Multiple start of the single axis control FB cannot be executed to an axis operated in the axes group. A stop caused by multiple start will result in Motion FB issue error to the axis during axes group operating (error code: 1AE2H). In other cases, Start not possible (error code: 1AFCH) will occur.

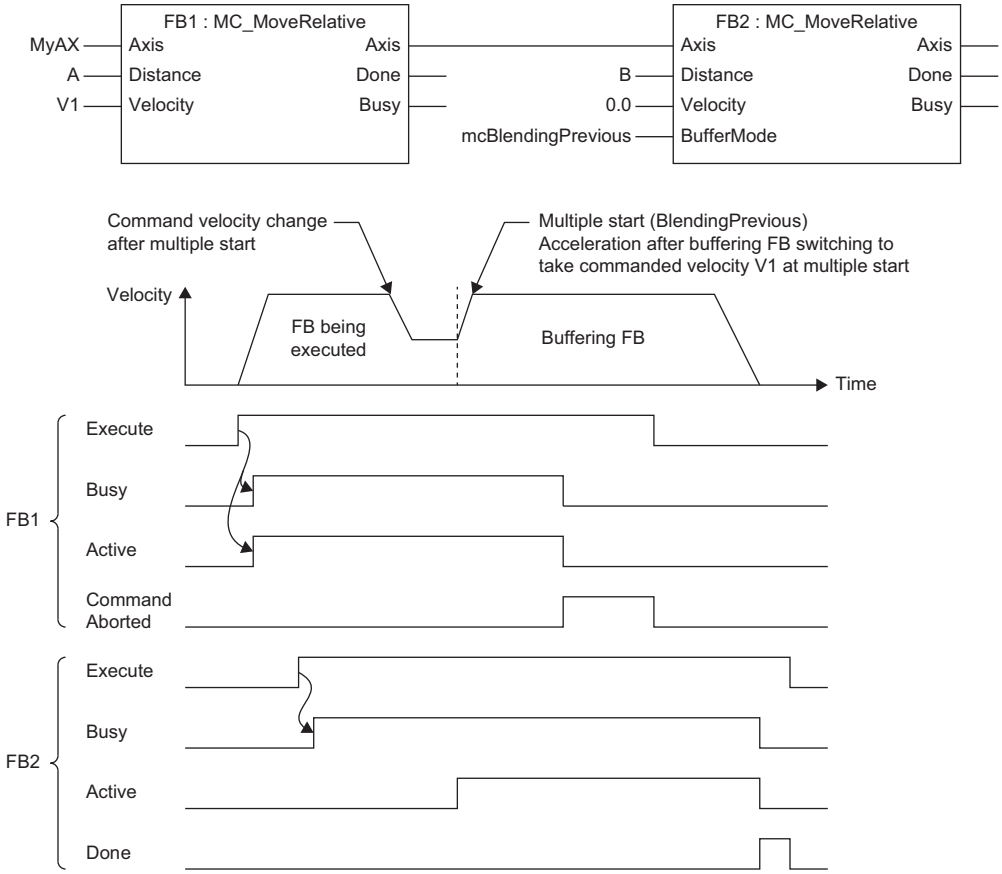
Buffer mode type

The following types can be specified to the buffer mode, and the type that can be specified differs depending on the FB.

Setting value	Buffer mode type	Description	Reference	
			During single axis operation	During multiple axes operation
0: mcAborting	Aborting	Aborts (cancels) the under-control FB and executes the next FB immediately.	Page 556 Aborting during single axis operation	Page 564 Aborting during multiple axes operation
1: mcBuffered	Buffered	Buffers the next FB on the under-control FB. If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.) Buffering FBs are executed in order after completion of the under-control FB.	Page 557 Buffered during single axis operation	Page 565 Buffered during multiple axes operation
2: mcBlendingLow	BlendingLow	Buffers the next FB on the under-control FB.*1 If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.) Buffering FBs are executed in order after the under-control FB reaches the target position. The lower target velocity between the under-control FB and the buffering FB is used as the switching speed.	Page 560 BlendingLow	Page 568 BlendingLow
3: mcBlendingPrevious	BlendingPrevious	Buffers the next FB on the under-control FB.*1 If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.) Buffering FBs are executed in order after the under-control FB reaches the target position. The target velocity of the under-control FB is used as the switching speed.	Page 558 BlendingPrevious	Page 566 BlendingPrevious
4: mcBlendingNext	BlendingNext	Buffers the next FB on the under-control FB.*1 If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.) Buffering FBs are executed in order after the under-control FB reaches the target position. The target velocity of the buffering FB is used as the switching speed.	Page 559 BlendingNext	Page 567 BlendingNext
5: mcBlendingHigh	BlendingHigh	Buffers the next FB on the under-control FB.*1 If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.) Buffering FBs are executed in order after the under-control FB reaches the target position. The higher target velocity value between the under-control FB and the buffering FB is used as the switching speed.	Page 560 BlendingHigh	Page 568 BlendingHigh

*1 Stops are not performed between the under-control FB and the buffering FB.

Point



- Up to two motion FBs can be buffered after multiple start in one axis and an axes group. If multiple start is executed when two FBs have already been multiple started, Warning Starting over Number of Buffering FBs (event code: 00D22H) occurs and the buffering FB waits for its analysis until under-control FB is completed. Even though the warning occurs each multiple start, filter setting can be set not to detect the warning. For details on filter setting, refer to the following.
  ☞ Page 1756 Filter setting
  When an error or a stop cause occurred in the under-control FB, FBs which are waiting for the analysis are interrupted.
- When Warning starting over number of buffering FBs (event code: 00D22H) occurs, note that multiple starts should not be executed until the under-control FB is completed. If the multiple FBs are waiting for the analysis by the multiple start, the next buffering FB may not be in order.
- Since multiple started FBs are executed immediately when Aborting has been specified, the FBs are not buffered. When the under-control FBs include a buffering FB, all buffering FBs are interrupted. However, as the FBs which are awaiting analysis are not interrupted, those FBs start after the multiple started FBs are completed by specifying Aborting.
- Do not multiple start FBs for which Aborting is specified three times or more in the same operation cycle. Buffering FB analysis disabled (error code: 1B03H) may occur.
- When an error or a stop cause occurs in the under-control FB, all buffering FBs are interrupted (the output of Abortion of execution (CommandAborted) becomes TRUE).

Command omission at multiple start

When omitting the commanded velocity, the acceleration specification, and the deceleration specification in an FB that executes multiple start, commanded velocity of "the previous FB of buffering FB" at multiple start is taken over. If the commanded velocity input does not exist in "the previous FB of buffering FB", buffering is executed with speed 0.0.

Point

When buffering with velocity 0.0 using Blending buffer mode type, the target position may not be reached when the velocity of the previous FB becomes 0.0 (switching speed), and the FB may not switch. When buffering with velocity 0.0, use Buffered buffer mode type.

- When FB switching is executed by multiple start, velocity change is executed to the target velocity of next FB. For the velocity waveform operation when the jerk is not specified with "0.0", refer to the following.
  ☞ Page 1078 Acceleration/deceleration method
- When multiple FBs are multiple started at the same execution cycle, the order of FBs to be buffered is uncertain. To determine the buffering order, execute multiple start after checking that the previous FB is started (Executing (Busy) is TRUE).

Relevant variables

Axis parameter (AxisName.Pr.)

Variable/structure name	Name	Details
OverrunOperation	Operation Setting at Overrun	Sets operation when an overrun occurs during operation. • 1: Immediate Stop (ImmediateStop) • 2: Keep Current Acceleration/Deceleration (KeepCurrentAcc)

Axis monitor data (AxisName.Md.)

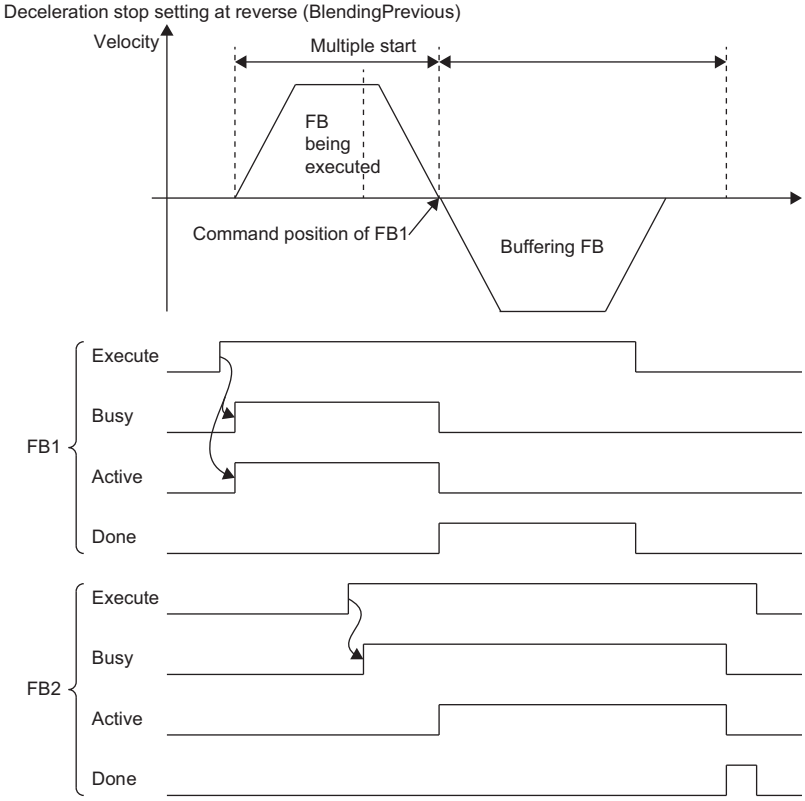
Variable/structure name	Name	Details
BufferingFBs	Number of Buffering FBs	Displays the number of buffering FBs (0 to 2).

Axes group parameter (AxesGroupName.Pr.)

Variable/structure name	Name	Details
OverrunOperation	Operation Setting at Overrun	Sets operation when an overrun occurs during operation. • 1: Immediate Stop (ImmediateStop)

Axes group monitor data (AxesGroupName.Md.)

Variable/structure name	Name	Details
BufferingFBs	Number of Buffering FBs	Displays the number of buffering FBs (0 to 2).

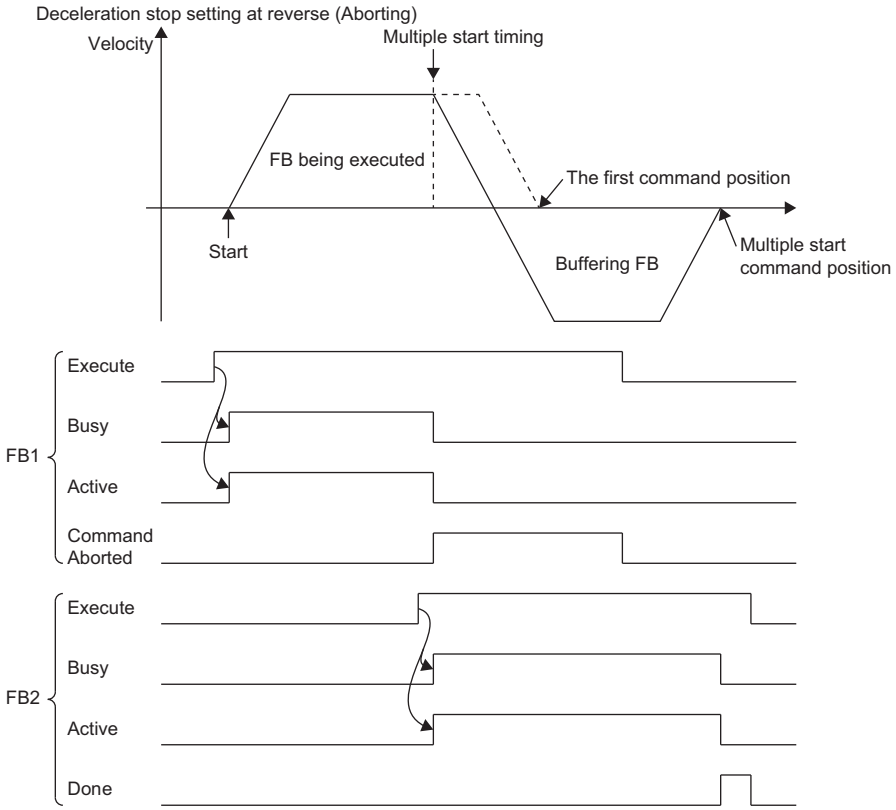


Multiple start during single axis operation

- When axis operation state is as follows, multiple start is enabled by starting a motion FB of another instance. (If the axis operation is in the "4: Standby (Standstill)" status, it is regarded as "start".)

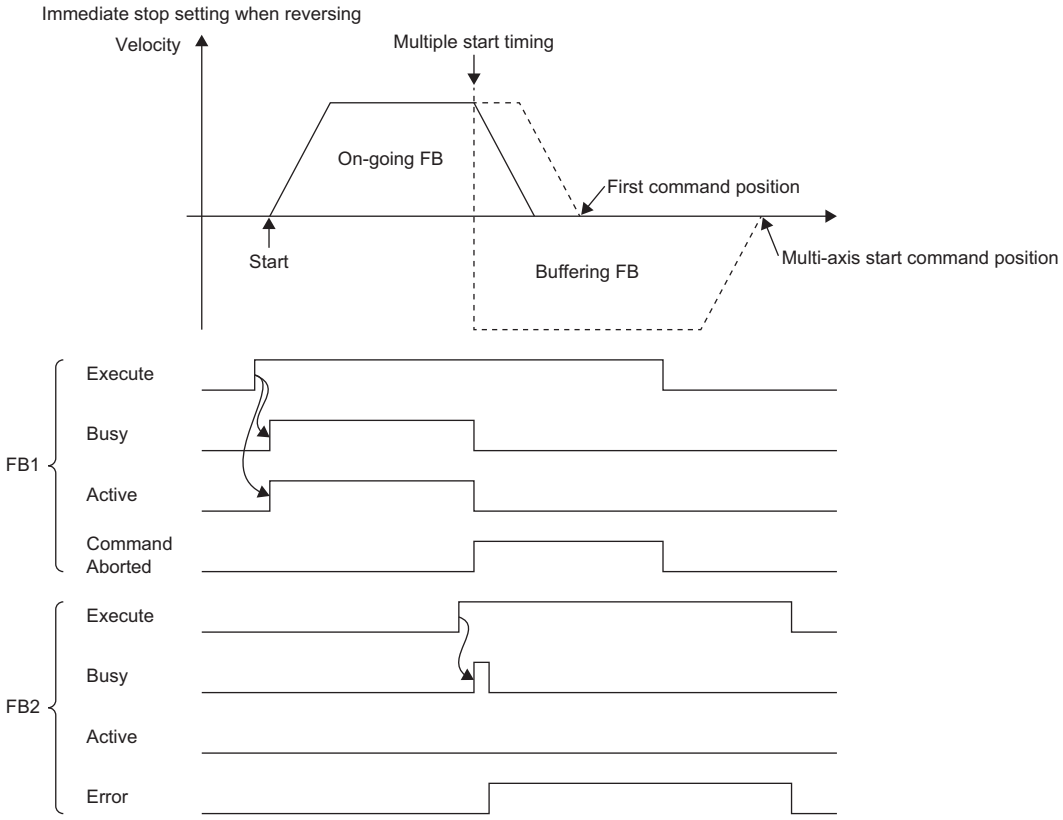
■Axis Status (AxisName.Md.AxisStatus) that can be multiple started
- 3: During homing (Homing) (Only MC_Stop (Forced Stop) is possible.)
- 5: During positioning operation (DiscreteMotion)
- 6: During continuous operation (ContinuousMotion)
- 7: During synchronous operation (SynchronizedMotion)

- When the buffering FB input includes Direction selection (Direction) and "4: Current Direction (mcCurrentDirection)" is selected, the previous FB operation direction is taken over.
- When the directions are different between the under-control FB and next FB in the single axis motion FB, the operation differs depending on the selection in the case of having Reverse rotation permission selection (Options (Options): bit 5). The operation is the same as the operation at reverse rotation permission in the case of not having Reverse rotation permission selection (Options (Options): bit5).
- When the direction is reversed while Blending is specified, a deceleration stop is executed at the target position of the under-control FB, and velocity change is executed to the target velocity of the buffering FB after the under-control FB is switched to the buffering FB. (It is the same operation as Buffered is specified.)



Deceleration stop setting at reverse (BlendingPrevious)

Operations with reverse rotation permission selection (Options (Options): bit5)



■When reverse is enabled

When reverse rotation permission (0: Allow) is set in Reverse rotation permission selection (Options (Options): bit5), a deceleration stop is executed once. After the deceleration stop is completed, operation is started to the changed direction.

■When reverse is disabled

When reverse rotation no permission (1: Do not allow) is set in Reverse rotation permission selection (Options (Options): bit5), Overrun error (error code: 1AE3H) occurs at switching and the axis decelerates to a stop.

Buffer mode that can be set

The following shows buffer modes that can be specified in the single axis control FB. For operation details on each FB, refer to the specifications of each FB.

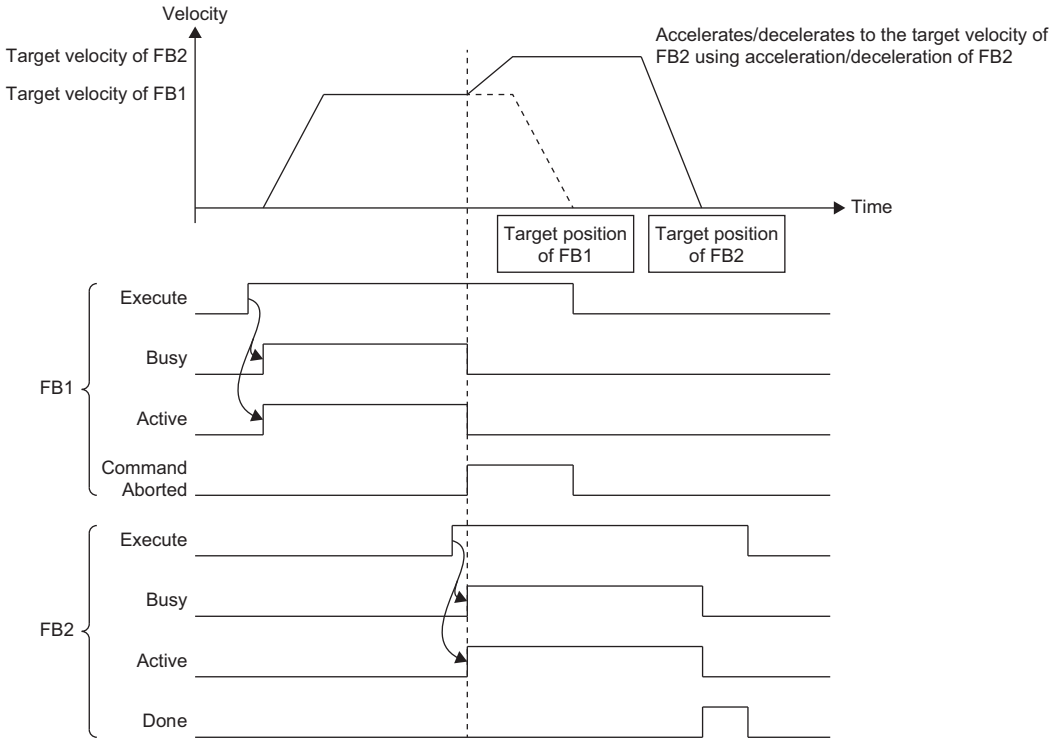
○: Buffer mode setting possible, —: Buffer mode setting not possible (axis error)

FB	Setting possible in FB			Completion output	Setting possible in the later motion FB		
	Aborting	Buffered	Blending		Aborting	Buffered	Blending
MC_Home (Homing)	—*1	—	—	Execution Completed (Done)	○*2	—	—
MC_Stop (Forced Stop)	○	—	—	Execution Completed (Done)	○*2	—	—
MC_MoveAbsolute (Absolute Value Positioning)	○	○	○	Execution Completed (Done)	○	○	○
MC_MoveRelative (Relative Value Positioning)	○	○	○	Execution Completed (Done)	○	○	○
MCv_Jog (JOG Operation)	—*1	—	—	Execution Completed (Done)	○	○	—
MCv_SpeedControl (Speed Control (Including Position Loop))	○	○	○	Target Velocity Reached (InVelocity)	○	○	—
MCv_PositionControl (Absolute Position Follow-up Control)	○	○	○	Target Position Reached (InAddress)	○	○	—
MC_MoveVelocity (Speed Control)	○	○	—	Target Velocity Reached (InVelocity)	○	○	—
MC_TorqueControl (Torque Control)	○	○	—	Target torque reached (InTorque)	○	○	—
MCv_PressureControl (Pressure Control)	○	○	—	Pressure Reached (InPressure)	○*3	○*3	—
MCv_CyclicPosition (Motion Cyclic Position Control)	○	—	—	Target Position Reached (InAddress)	○	○	—
MCv_CyclicVelocity (Motion Cyclic Speed Control)	○	—	—	Target Velocity Reached (InVelocity)	○	○	—
MCv_CyclicTorque (Motion Cyclic Torque Control)	○	—	—	Target torque reached (InTorque)	○	○	—
MC_CamIn (Cam Operation Start)	○	○	—	Cam cycle completion (EndOfProfile)	○	○	—
MC_GearIn (Gear Operation Start)	○	○	—	Gear ratio reached (InGear)	○	○	—
MC_CombineAxes (Addition/Subtraction Positioning)	○	○	—	In synchronization (InSync)	○	○	—
MCv_SmoothingFilter (Smoothing Filter)	—*1	—	—	—	○*2	—	—
MCv_DirectionFilter (Moving Direction Restriction Filter)	—*1	—	—	—	○*2	—	—
MCv_SpeedLimitFilter (Speed Limit Filter)	—*1	—	—	—	○*2	—	—
MCv_BacklashCompensationFilter (Backlash Compensation Filter)	—*1	—	—	—	○*2	—	—
MCv_AdvancedSync (Advanced Synchronous Control)	—*1	—	—	Cam cycle completion (CycleZeroPoint)	○	○	—
MCv_MoveWait (Axis Control Start Wait)	—*1	—	—	Execution Completed (Done)	○	○	—

*1 Multiple start cannot be executed because this FB can be started only when Axis Status (AxisName.Md.AxisStatus) is "4: Standby (Standstill)".

*2 Only MC_Stop (Forced Stop) is possible.

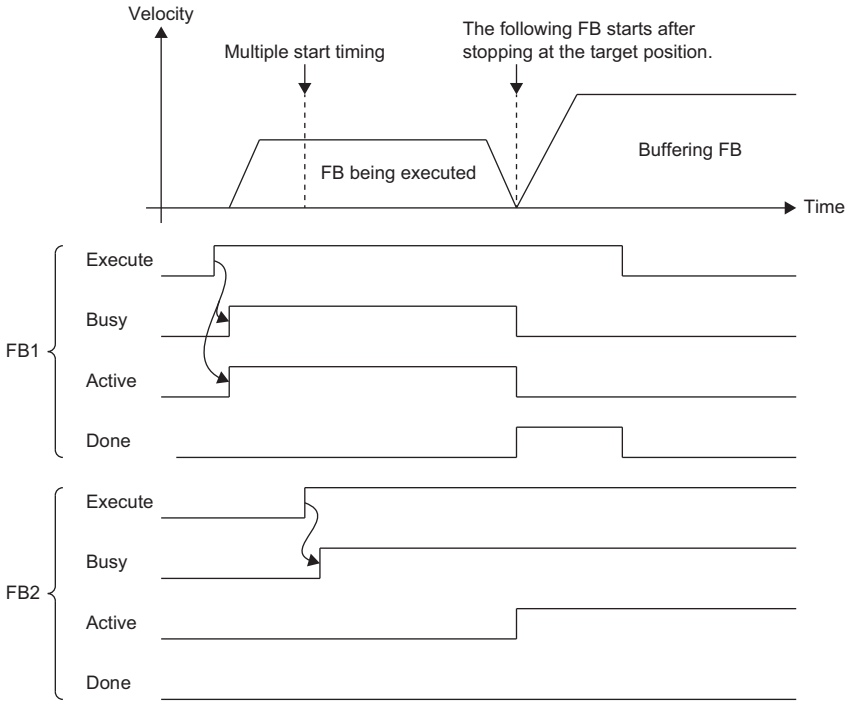
*3 MCv_PressureControl (Pressure Control) cannot be specified.



Aborting during single axis operation

The under-control FB is interrupted and the next FB is executed.

Since a buffer is not used, an error does not occur even if two of under-control FBs have already been in buffering, and the FB is executed. (All FBs during buffering are interrupted.)

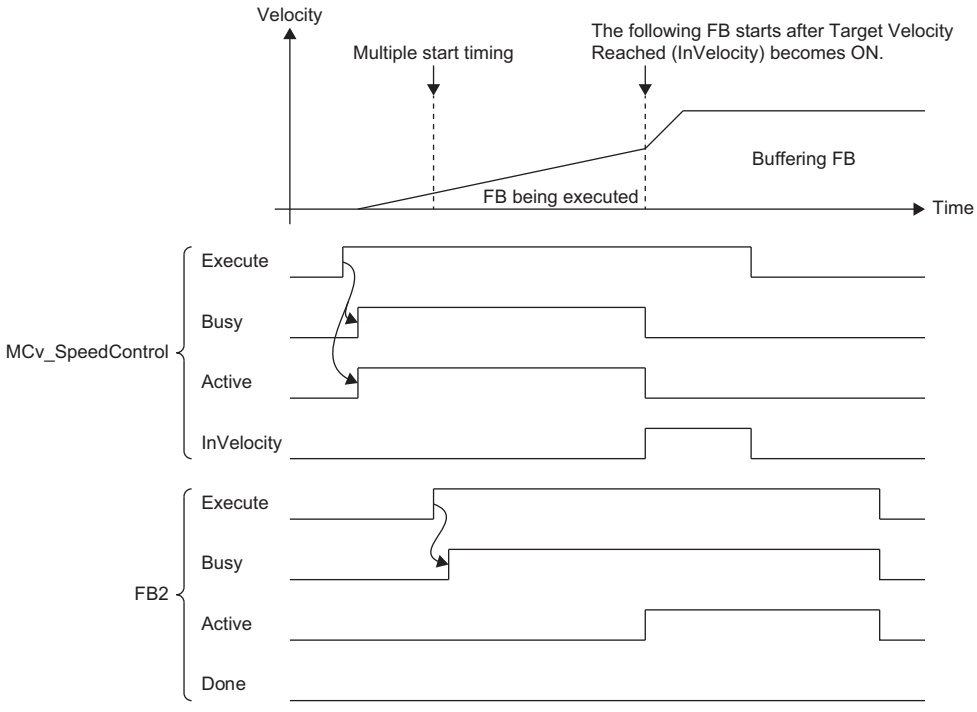


When omitting to specify the buffer mode, this operation is performed.

An operation example when Aborting is executed to the under-control FB1 with the linked start FB2 is shown below.

Buffered during single axis operation

Multiple started FBs are buffered and wait (Executing (Busy) is TRUE) until the under-control FB is completed. After the under-control FB is normally completed, multiple started FBs are performed in the order of being buffered.



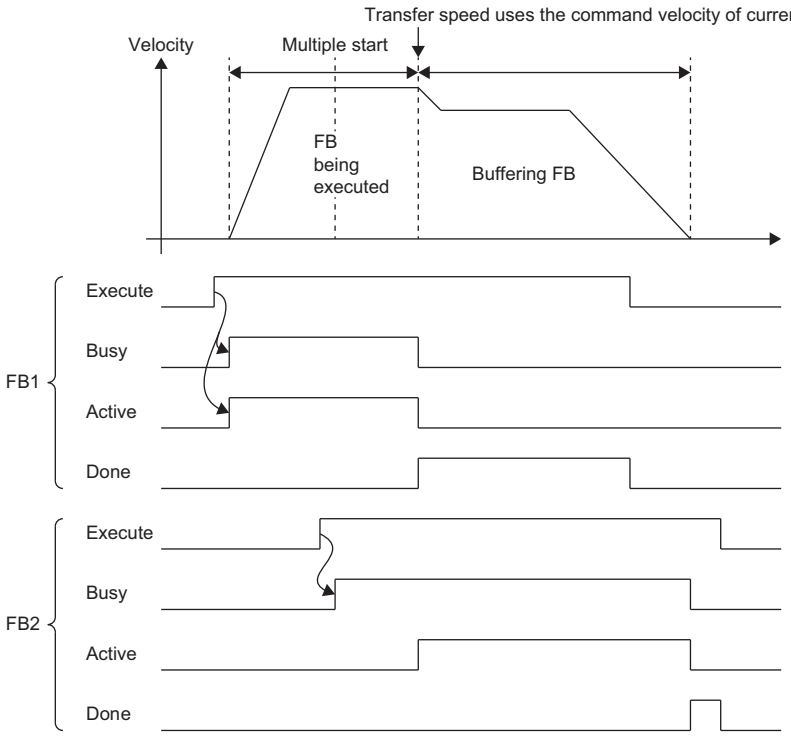
Conditions to determine completion are different depending on the motion control FB, and the FB may not be in the stop status with speed 0 at completion. For details, refer to the following.

☞ Page 552 Multiple start during single axis operation

Ex.

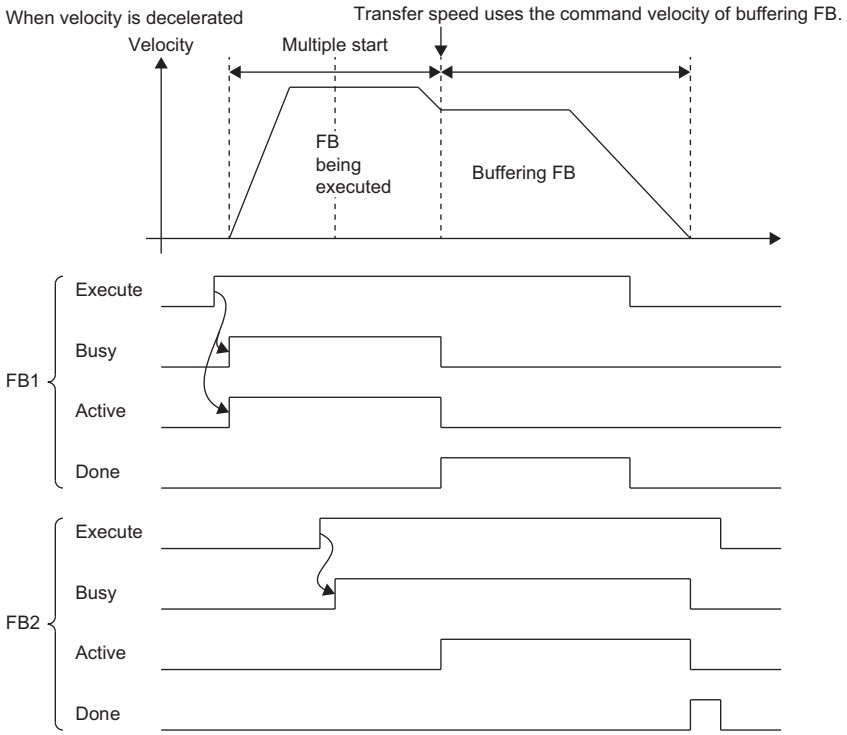
When an FB is multiple started with Buffered in MCv_SpeedControl (Speed Control (Including Position Loop))

In MCv_SpeedControl (Speed Control (Including Position Loop)), the FB is determined that it is completed when Target velocity reached (InVelocity) becomes TRUE, and the following buffering FB is executed. (The current speed at this time is used as the switching speed.)



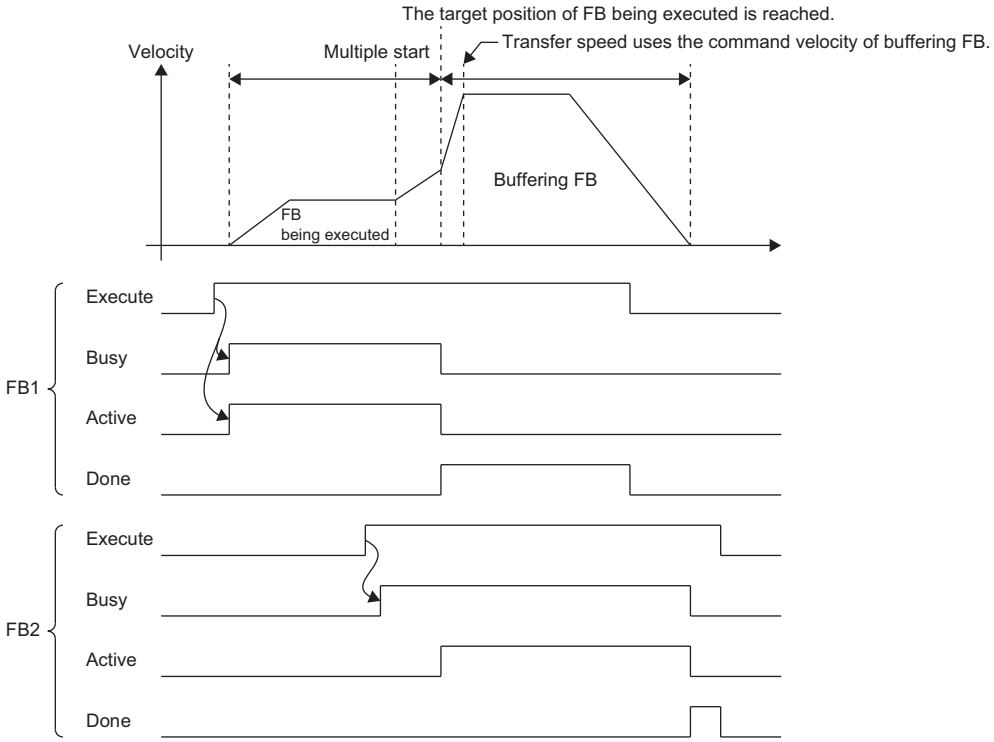
Blending during single axis operation

Multiple started FBs are buffered and wait until the under-control FB is completed. After the under-control FB reached the target position, buffering FBs are performed in order. In this case, the switching speed differs depending on the mode specified in the buffer mode.



■BlendingPrevious

The FB is operated at the speed of the current under-control FB to the target position of the under-control FB. After switching to the FB that is during buffering, velocity change is executed to the target velocity of the buffering FB.



■BlendingNext

The FB is operated so that the velocity becomes the target velocity of the FB in buffering at the target position of the under-control FB.

Depending on the multiple start timing, the movement amount to change the speed to the target velocity of the FB in buffering may be insufficient at the target position of the under-control FB. In this case, velocity change is executed immediately, but the velocity cannot reach the target velocity of the FB that is during buffering at the target position of the under-control FB. If the target position of an under-control FB is reached during acceleration/deceleration, control is changed by the acceleration/deceleration of the buffering FB at that time.

When the acceleration/deceleration method specified in the under-control FB is jerk acceleration/deceleration, if the next FB is multiple started during acceleration/deceleration of the under-control FB, the target speed of the buffering FB may not be reached at the target position of the under-control FB.

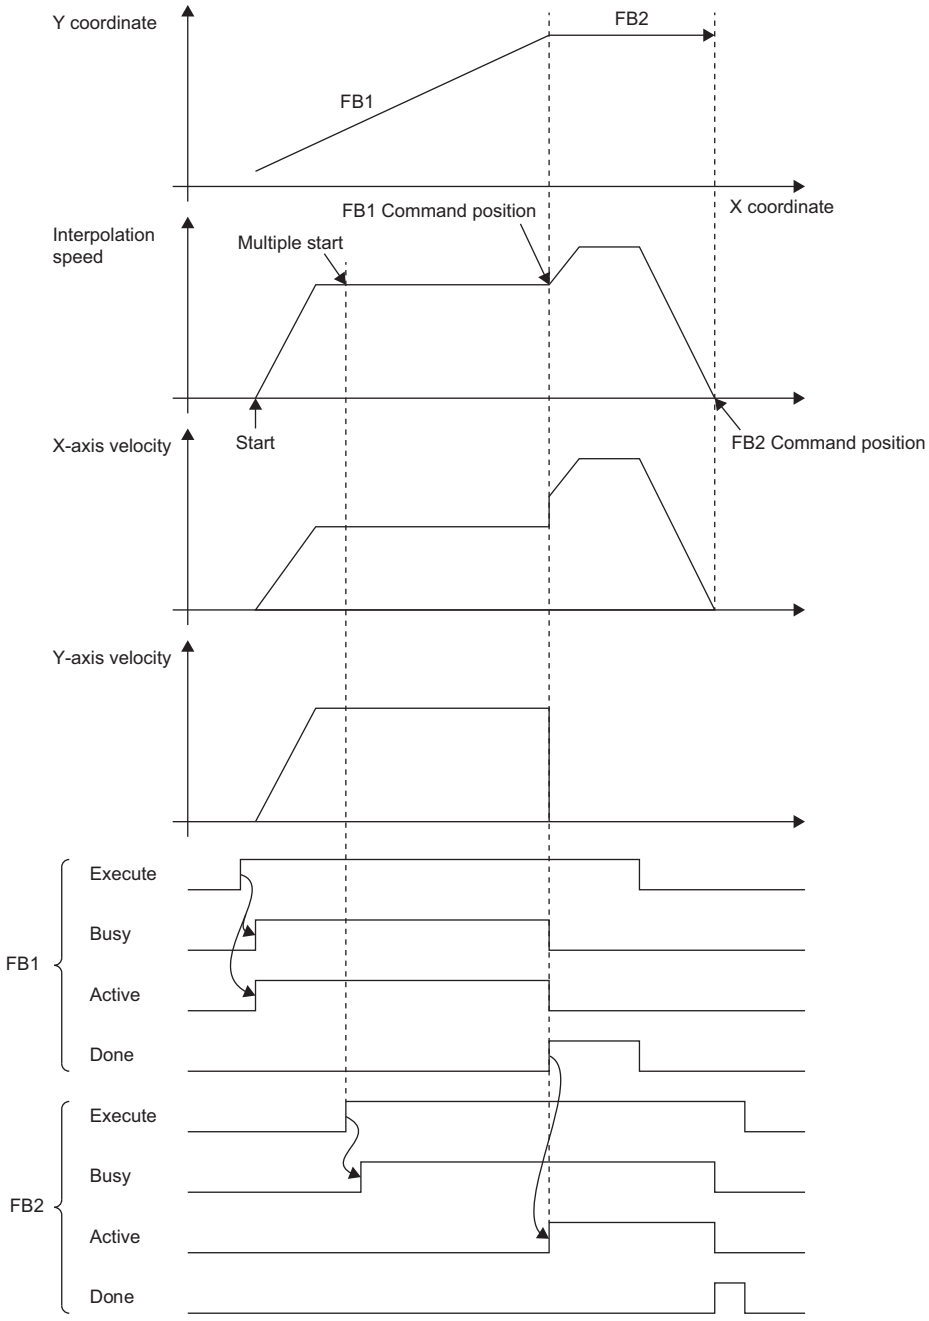
■BlendingLow

The slower target velocity between the under-control FB and the buffering FB is used as the switching speed.
The operation is same as BlendingPrevious when the under-control FB target velocity is slower, and it is same as BlendingNext when the buffering FB target velocity is slower.

■BlendingHigh

The higher target velocity between the under-control FB and the buffering FB is used as the switching speed.
The operation is same as BlendingPrevious when the under-control FB target velocity is higher, and it is same as BlendingNext when the buffering FB target velocity is higher.

Multiple start during multiple axes operation

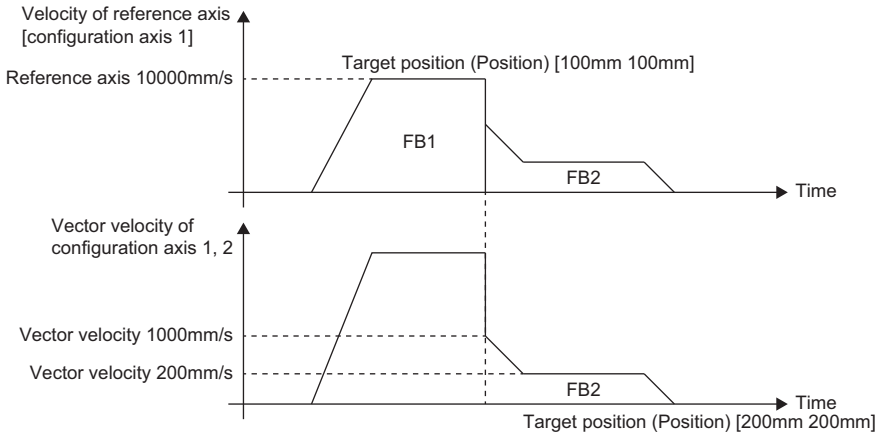


- When the axes group operation state is as follows, multiple start is enabled by executing the motion FB of another instance. (If the axis operation is in the "4: Standby (GroupStandby)" status, it is regarded as "start".)

■Axes Group Status (AxesGroupName.Md.GroupStatus) that can be multiple started

- 5: Operating (GroupMoving)

- In multiple start during multiple axes operation, the current interpolation speed of the under-control FB is used as the switching speed. Therefore, acceleration/deceleration may not be executed and a rapid velocity change may occur depending on the movement amount and direction of each axis in the buffering FB.



Example of speed pattern for each axis at switching FB (BlendingPrevious)

- When multiple start is performed by specifying Aborting or Blending, if the under-control FB (FB1) or next FB (FB2) has Velocity mode (VelocityMode) input and the velocity mode settings are different between FBs, Multiple Start Velocity Mode Specified Mismatch Warning (event code: 00D11H) is output because the velocity may change suddenly. In such a case, FB1 Velocity mode (VelocityMode) is used in FB1 and FB2 Velocity mode (VelocityMode) is used in FB2 to control. In this case, the switching speed is controlled using only values. (Unit/speed conversion by Velocity mode (VelocityMode) is not executed.)

Ex.

When multiple start by specifying BlendingPrevious from FB1 with the reference axis velocity to FB2 with the vector velocity.

The operation is carried out so that the reference axis velocity of FB1 becomes the velocity set in Velocity (Velocity) (reference axis velocity 1000 [mm/s]). The reference axis velocity at the target position of FB1 is regarded as the switching speed and the current vector velocity value of FB2 without conversion, and it accelerates and decelerates the vector velocity (200 [mm/s]) set in Velocity (Velocity) of FB2.

- Multiple start of the single axis control FB cannot be executed to the axis that is during operation in the axes group. If it is executed, Motion FB issue error to the axis during axes group operating (error code: 1AE2H) will occur in the target axis, and the axes group FB under execution will stop.

Buffer mode that can be set

The following shows buffer modes that can be specified in the multiple axes control FB. For operation details on each FB, refer to the specifications of each FB.

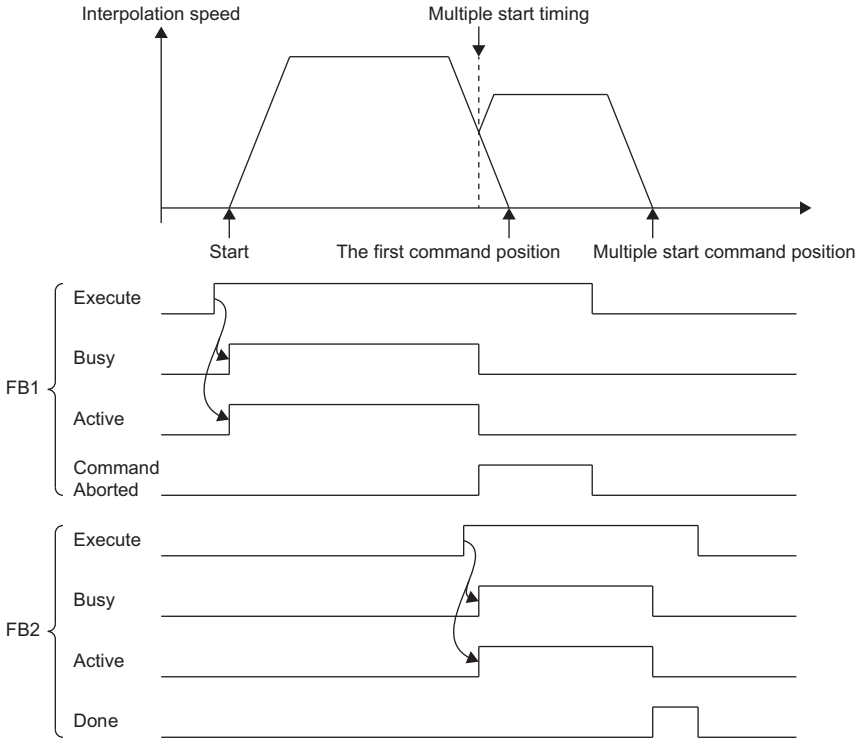
○: Buffer mode setting possible, —: Buffer mode setting not possible (axes group error)

FB	Setting possible in FB			Completion output	Setting possible in the later motion FB		
	Aborting	Buffered	Blending		Aborting	Buffered	Blending
MC_GroupStop (Group Forced Stop)	—*1	—	—	Execution Completed (Done)	○*2	—	—
MCv_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control)	○	○	○	Execution Completed (Done)	○	○	○
MCv_MoveLinearInterpolateRelative (Relative Value Linear Interpolation Control)	○	○	○	Execution Completed (Done)	○	○	○
MCv_MoveCircularInterpolateAbsolute (Absolute Value Circular Interpolation Control)	○	○	○	Execution Completed (Done)	○	○	○
MCv_MoveCircularInterpolateRelative (Relative Value Circular Interpolation Control)	○	○	○	Execution Completed (Done)	○	○	○
MCv_MovePositioningData (Multiple Axes Positioning Data Operation)	○	○	—	Execution Completed (Done)	○	—	—
MCv_GroupMoveWait (Axis Group Control Start Wait)	—*3	—	—	Execution Completed (Done)	○	○	—

*1 When it is started during axis operation, the operation will be same as Aborting.

*2 Only MC_GroupStop (Group Forced Stop) is possible.

*3 Multiple start cannot be executed because this FB can be started only when Axes Group Status (AxesGroupName.Md.GroupStatus) is "4: Standby (GroupStandby)".



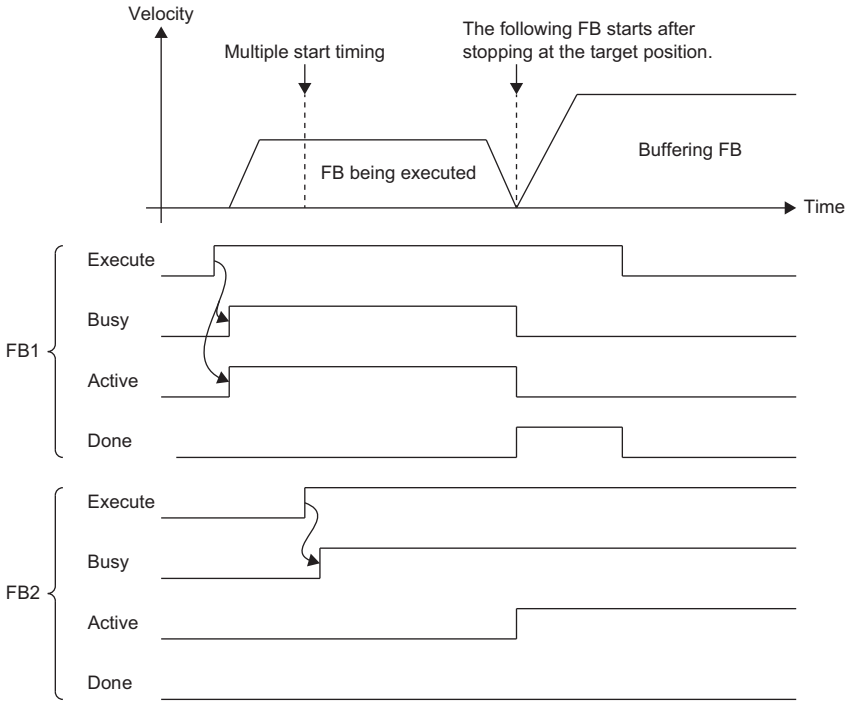
Aborting during multiple axes operation

The under-control FB is interrupted and the multiple started FB is executed.

Since a buffer is not used, an error does not occur even if two of under-control FBs have already been in buffering, and the FB is executed. (All FBs during buffering are interrupted.)

When omitting to specify the buffer mode, this operation is performed.

An operation example when Aborting is executed to the under-control FB1 with the linked start FB2 is shown below.

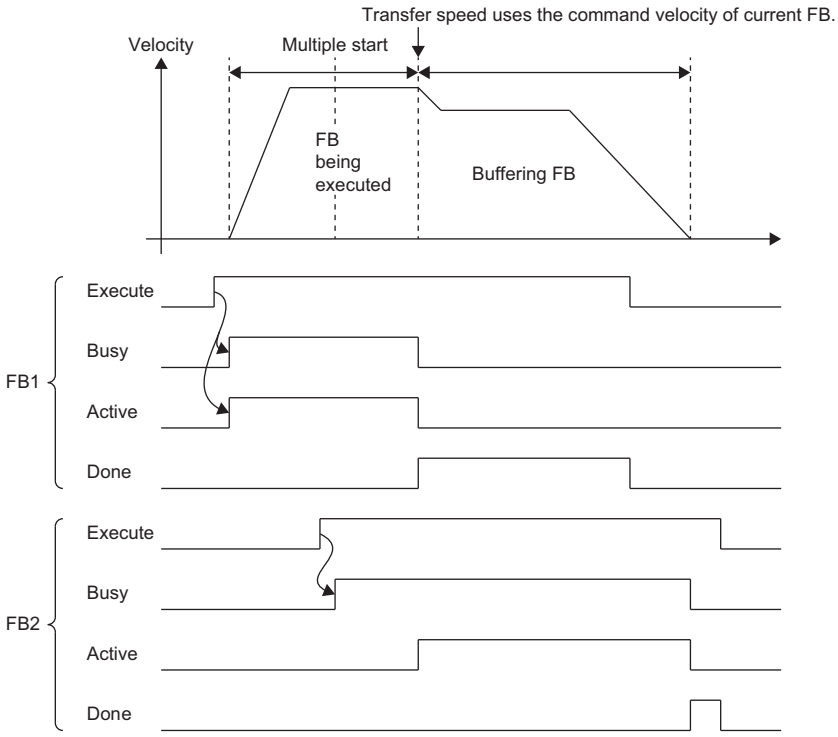


Point

At multiple start during multiple axes operation, if Software stroke limit over (target position) (error code: 1A80H) or any other axes group errors are detected at the same time as when the FB is being switched, the operation may stop immediately regardless of the setting in Stop Selection at Stop Cause Occurrence (AxisName.Pr.StopMode_General) of the axes group.

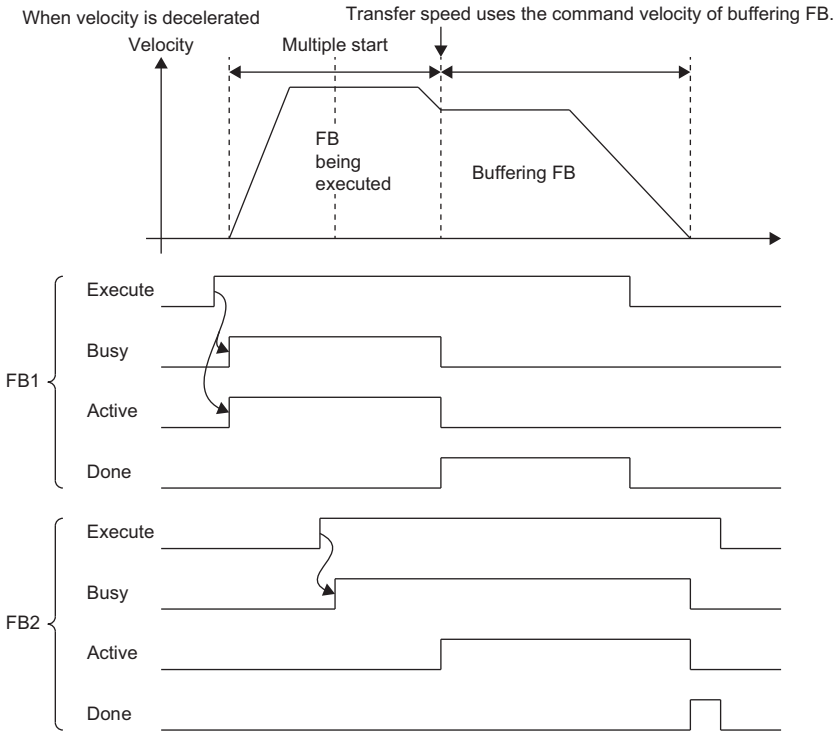
Buffered during multiple axes operation

Multiple started FBs are buffered and wait until the under-control FB is completed. After the under-control FB is normally completed, multiple started FBs are performed in the order of being buffered.



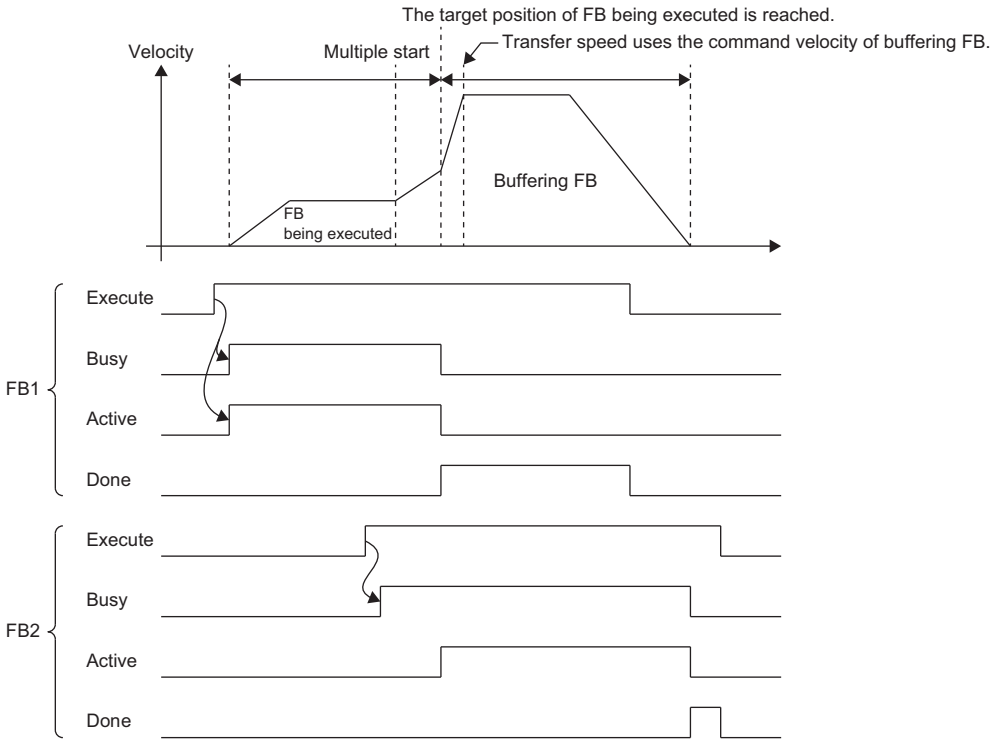
Blending during multiple axes operation

Multiple started FBs are buffered and wait until the under-control FB is completed. After the under-control FB reached the target position, buffering FBs are performed in order. In this case, the switching speed differs depending on the mode specified in the buffer mode.



■BlendingPrevious

The FB is operated with the interpolation velocity of current under-control FB to the target position of the under-control FB. After switching to the FB that is during buffering, velocity change is executed to the target velocity of the buffering FB.



■BlendingNext

The FB is operated so that the interpolation velocity becomes the target velocity of FB that is during buffering at the target position of the under-control FB.

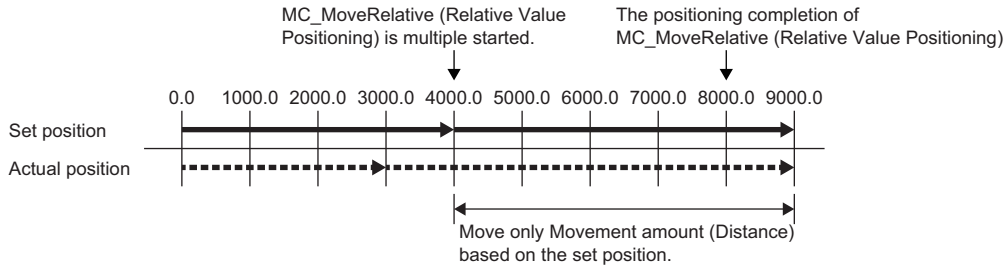
Depending on the multiple start timing, the movement amount to change the speed to the target velocity of the FB in buffering may be insufficient at the target position of the under-control FB. In this case, velocity change is executed immediately, but the velocity cannot reach the target velocity of the FB that is during buffering at the target position of the under-control FB. If the target velocity of an under-control FB is reached during acceleration/deceleration, control is changed by the acceleration/deceleration of the buffering FB at that time.

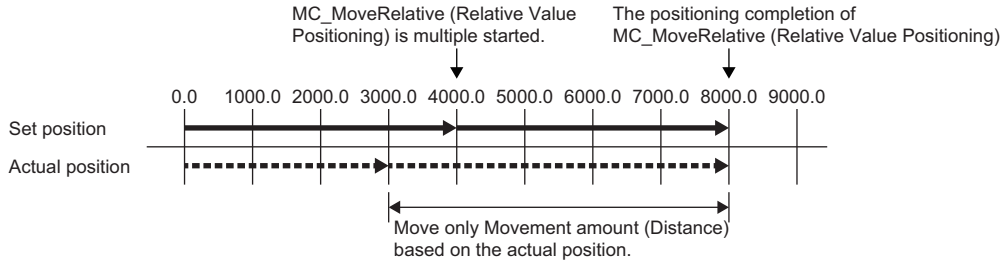
When the acceleration/deceleration method specified in the under-control FB is jerk acceleration/deceleration, if the next FB is multiple started during acceleration/deceleration of the under-control FB, the target speed of the buffering FB may not be reached at the target position of the under-control FB.

■BlendingLow

The smaller target velocity between the under-control FB and the buffering FB is used as the switching velocity.
When the smaller switching velocity is the under-control FB, the control is the same as BlendingPrevious, and when the smaller switching velocity is the buffering FB, the control is the same as BlendingNext.

■BlendingHigh





The larger target velocity between the under-control FB and the buffering FB is used as the switching velocity.
When the larger switching velocity is the under-control FB, the control is the same as BlendingPrevious, and when the larger switching velocity is the buffering FB, the control is the same as BlendingNext.

Options of buffering FB

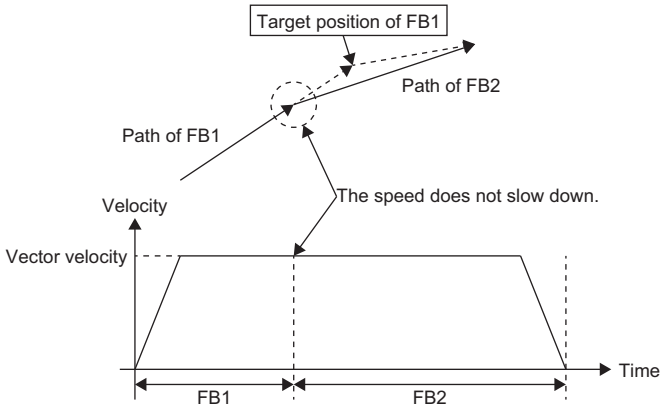
Set the option of the function used for the buffering FB by Options (Options) of the buffering FB. For the positioning control FB which can be specified, refer to operation details on each positioning control FB.
The option to be used by the multiple start is shown below.

Positioning selection in the buffer mode (Options (Options): bit3)

When the relative value positioning control is multiple started, the relative value positioning control from set position or actual position is carried out by Position selection at the multiple start of FB (Options (Options): bit 3).
The axis type which does not have the actual position ignores this setting.

Setting value	Description
0: Set position	The relative position control from set position (Example) When multiple start is performed with Movement amount (Distance) set to "5000.0" and Options (Options) set to "00000000H (bit 3 is 0: Set position)" 
1: Actual position	The relative position control from actual position (Example) When multiple start is performed with Movement amount (Distance) set to "5000.0" and Options (Options) set to "00000008H (bit 3 is 1: Actual position)" 

Reverse rotation permission selection (Options (Options): bit 5)



In the single axis motion FB, reverse rotation is allowed when the operation direction differs between the under-control FB and the buffering FB. For details, refer to the following.
☞ Page 552 Multiple start during single axis operation

Setting value	Description
0: Allow	Reverse rotation is allowed. Performs a deceleration stop once, and starts operation in the changed direction after deceleration stop is completed.
1: Not allowed	Reverse rotation is not allowed. When switched, Overrun error (error code: 1AE3H) occurs and a deceleration stop is performed.

Near pass

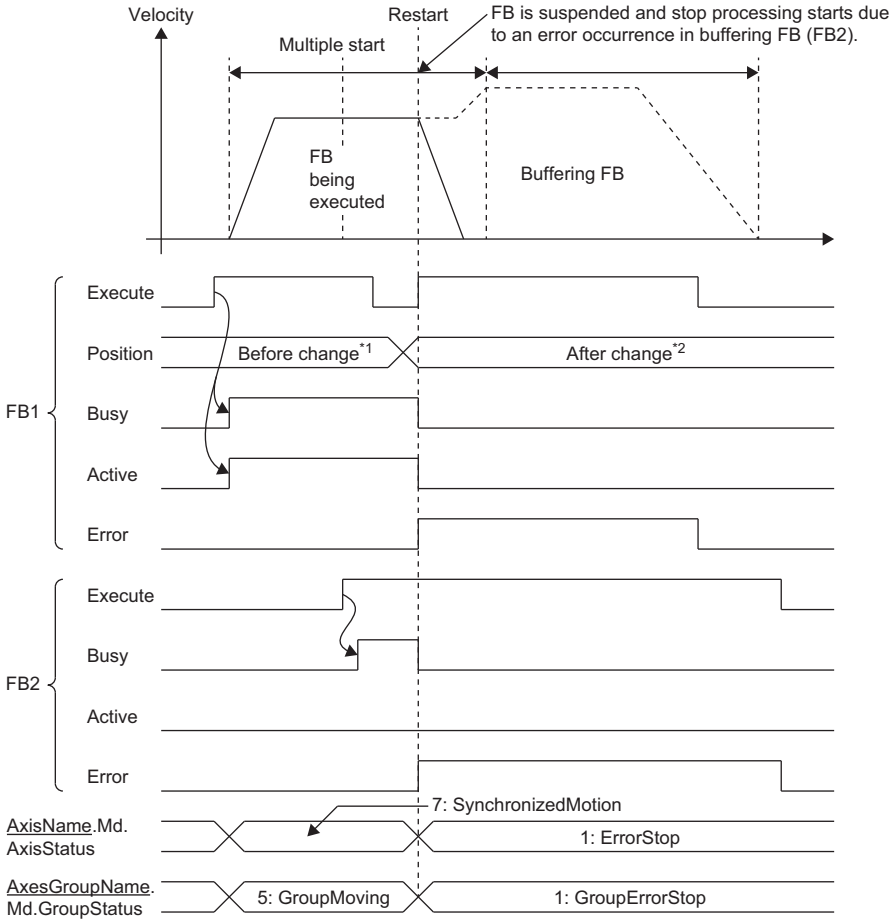
At multiple start by Blending, near pass is performed to suppress machine vibration which occurs at switching of the positioning control FB.
The remainder of the movement amount which occurs at the end of the positioning control FB is used for the next one.
Command velocity does not decrease and machine vibration which occurs by the velocity change can be suppressed as the positioning is not carried out for each positioning control FB.
Since the alignment is not performed every positioning control FB, the operation is controlled in a path that passes near the position set in the FB.

Ex.
For multiple starting the 2-axes linear interpolation control with Blending (multiple start of FB2 during control of FB1)

Precautions

At multiple start by Blending, the command velocity may not reach the target velocity if the movement amount of the previous FB is small.

Combination with retrigger/continuous update



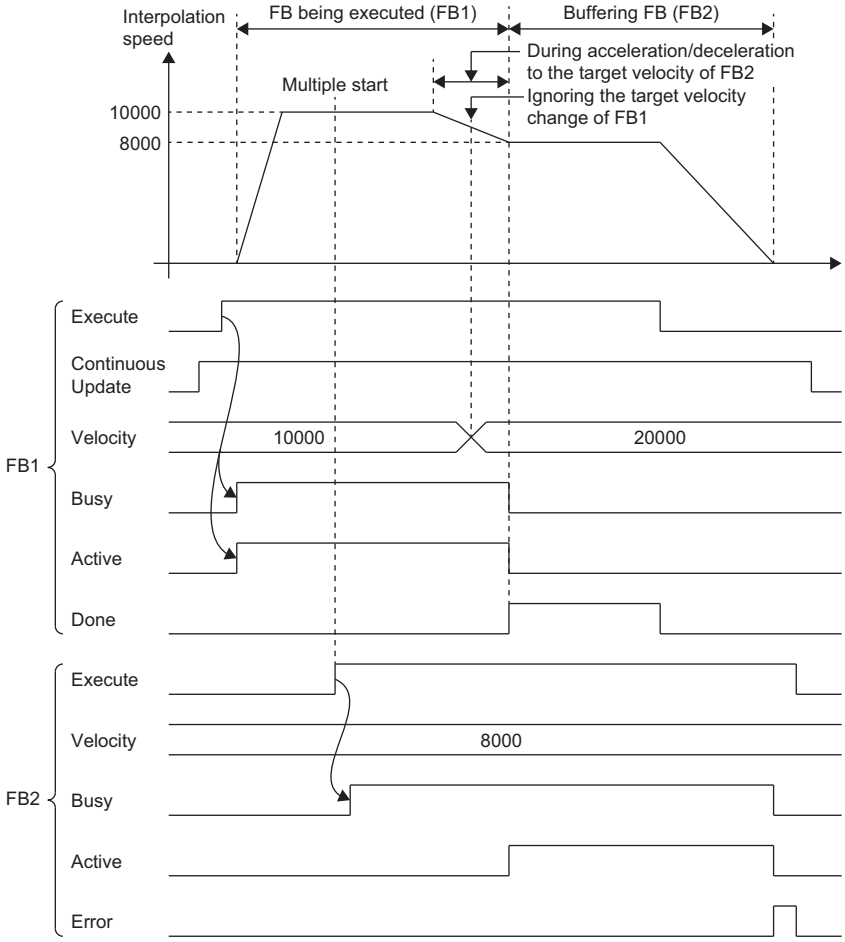
Reanalysis of the buffering FB by retrigger/continuous update

When the target position or the target velocity is changed by retrigger/continuous update for the under-control FB, the reanalysis of the buffering FB may be needed.

As a result of reanalysis, when an error occurs in any of the FBs, Axis Status (AxisName.Md.AxisStatus) becomes "1: Stopping on error (ErrorStop)" or Axes Group Status (AxesGroupName.Md.GroupStatus) becomes "1: Stopping on error (GroupErrorStop)" and the under-control FB is interrupted and stopped. (The buffering FB is canceled.)

Ex.

The changed target position is out of the software stroke limit range by retriggering the under-control FB.



*1 The target position is within the software stroke limit range.

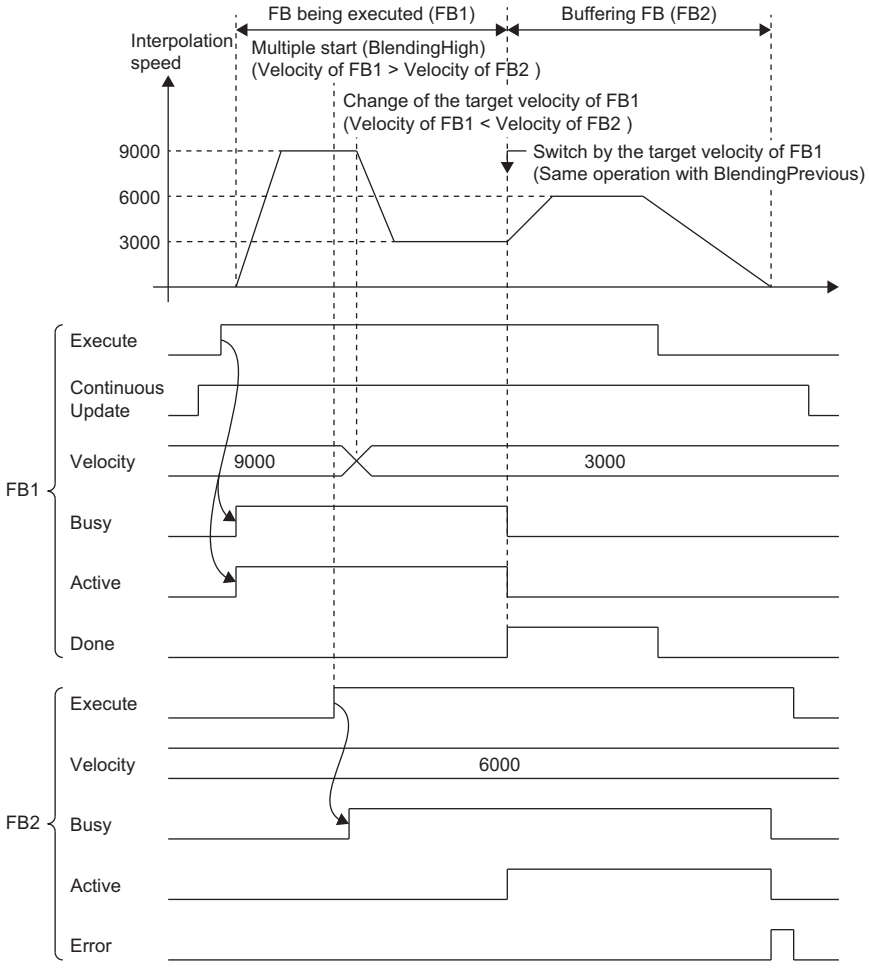
*2 The target position is out of the software stroke limit range.

BlendingNext changes target velocity at accelerating/decelerating

As BlendingNext is specified and the multiple start is executed, while the buffering FB is accelerating/decelerating to its target velocity (transfer speed), the target velocity change of under-control FB is not allowed.
The target velocity change is allowed if it is changed by Velocity Override Factor (AxisName(AxesGroupName).Cd.VelocityOverride).

After the target velocity of the buffering FB is reached by acceleration/deceleration by BlendingNext, the velocity change by the input variable of under-control FB is allowed. However, the velocity change value during acceleration/deceleration by BlendingNext is ignored even if a retrigger/continuous update is performed after the target velocity of the buffering FB is reached.
Also, if the target velocity is changed with the under-control FB, acceleration/deceleration is performed toward the target velocity of the buffering FB after the FB is switched.

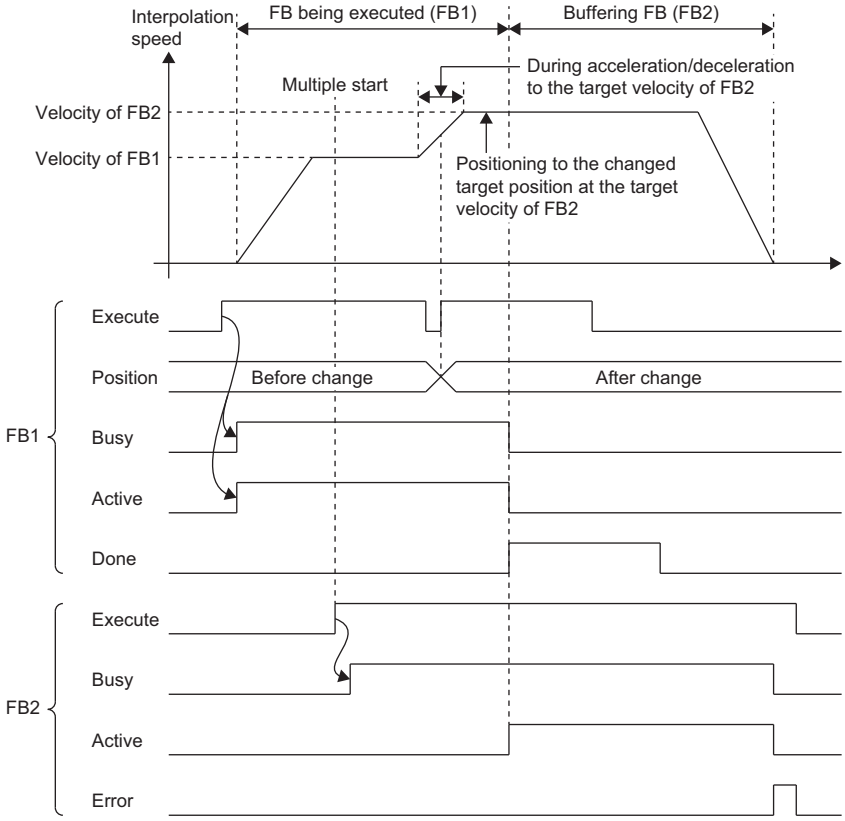
BlendingLow/BlendingHigh changes target velocity after multiple start



Multiple start by BlendingLow/BlendingHigh determines whether to switch with the velocity of the under-control FB or the buffering FB.

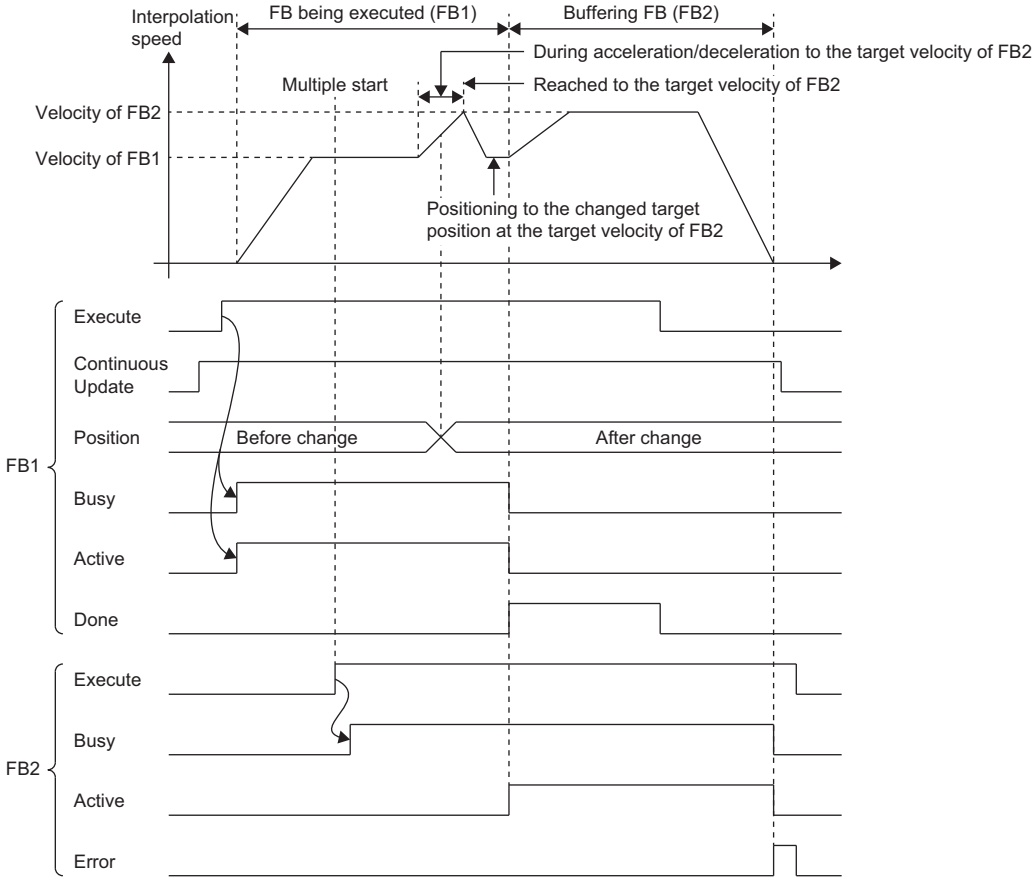
Therefore, if the size related to the target velocity between the under-control FB and the buffering FB is changed by target velocity change after multiple start, the switching velocity is still determined as the target velocity that was determined at multiple start.

When the velocity for the under-control FB and buffering FB is the same at multiple start, the velocity of the under-control FB is used for switching for both BlendingLow and BlendingHigh. Therefore, if the target velocity is changed after multiple start, the under-control FB velocity after the change is used for switching.



Ex.

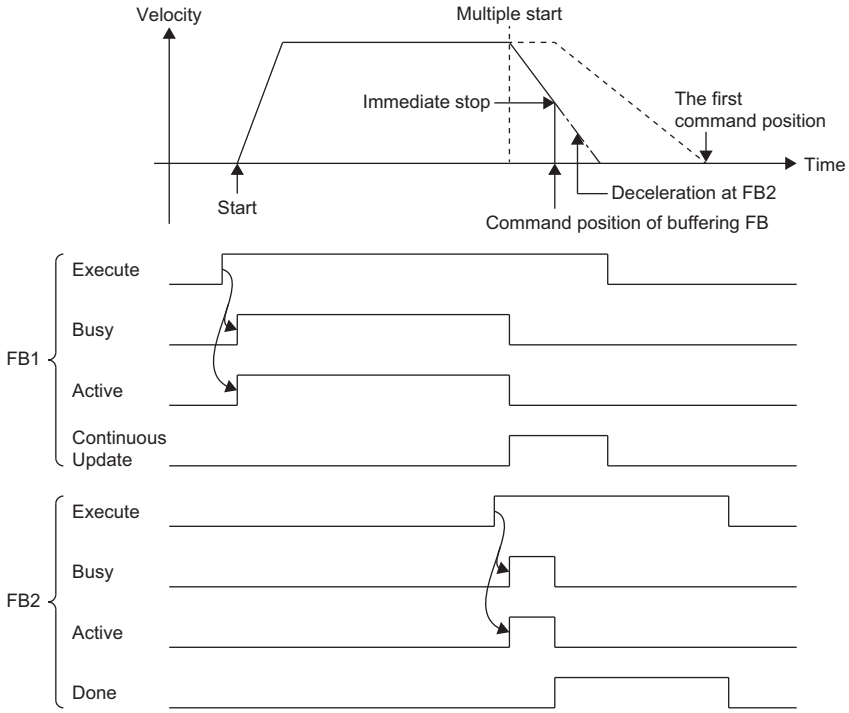
When the target velocity is changed after multiple start by BlendingHigh



BlendingNext changes target position/movement distance at accelerating/decelerating

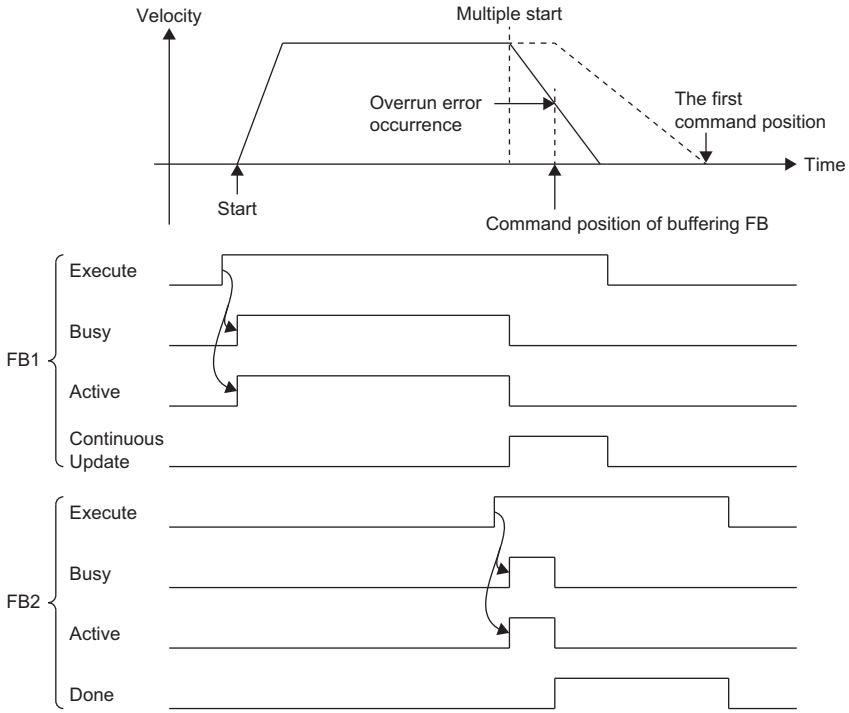
The following figure shows the operation in which the target position/movement distance is changed during acceleration/deceleration to the target velocity (transfer speed) of the buffering FB at multiple start by specifying BlendingNext.
When the movement amount is increased by the target position/movement distance change, positioning is executed to the target position/movement distance changed with the target velocity (transfer speed) of the buffering FB.

When the movement amount is reduced by the target position/movement distance change, the FB is switched during acceleration/deceleration to the target velocity (transfer speed) of the buffering FB. Also, the operation direction is reversed when the target position/movement distance is changed to a position before the current position.
For operations in the reversed direction, refer to the following.
☞ Page 552 Multiple start during single axis operation



Precautions

- When deceleration distance of a buffering FB cannot be secured with the switching speed and the target position is overrun at switching to the buffering FB, automatic deceleration operation is performed according to the setting of Operation Setting at Overrun (AxisName(AxesGroupName).Pr.OverrunOperation).



■When "1: Immediate Stop (ImmediateStop)" is set

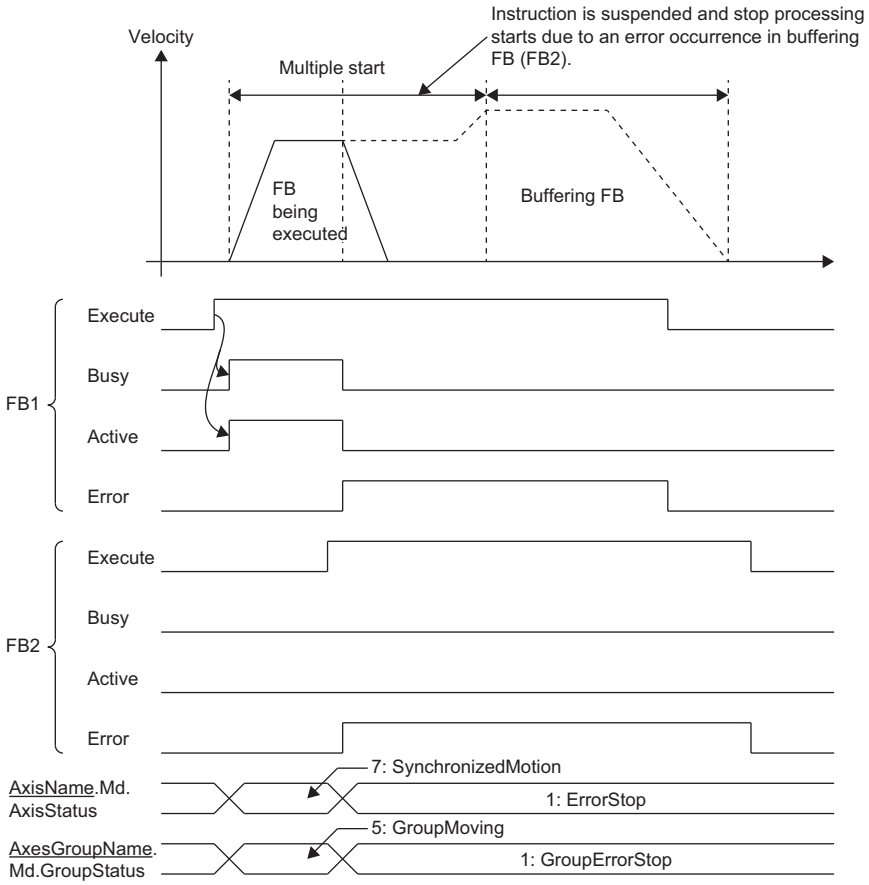
The axis starts deceleration immediately, and it stops immediately at reaching the target position after outputting Overrun Warning (event code: 00D10H).

■When "2: Keep Current Acceleration/Deceleration (KeepCurrentAcc)" is set (Only for single axis)

The axis starts deceleration immediately, and it stops after exceeding the target position. When the stop address is exceeded, Overrun error (error code: 1AE3H) is output. However, when the error occurs, the operation stops according to the setting of Stop Selection at Stop Cause Occurrence (AxisName.Pr.StopMode_General). To stop the axis after it exceeds the target position, set "2: Keep Current Acceleration/Deceleration (KeepCurrentAcc)" in Stop Selection at Stop Cause Occurrence (AxisName.Pr.StopMode_General).

Point

When a new FB is multiple started during deceleration due to movement amount shortage, the operation becomes as follows.



[When the Operation Setting at Overrun (AxisName.Pr.OverrunOperation) setting is "2: Keep Current Acceleration/Deceleration (KeepCurrentAcc)"]

- If the target position has already been reached when the multiple start happens (when Overrun error (error code: 1AE3H) occurs), the buffering FB will be disabled.
- If the target position has not been reached when the multiple start happens and if Aborting and Blending are set, deceleration will be canceled. If Buffered is set, the multiple start will be executed but canceled with Overrun error (error code: 1AE3H) occurrence.

[When the Operation Setting at Overrun (AxisName.Pr.OverrunOperation) setting is other than "2: Keep Current Acceleration/Deceleration (KeepCurrentAcc)"]

- If a new FB is multiple started when Aborting and Blending are set, deceleration stop will be canceled.
- If a new FB is multiple started when Buffered is set, automatic deceleration will be continued. The multiple started FBs will be executed after the axis stops.

- If an error occurs in the following FB analysis processing at multiple start, Axis Status (AxisName.Md.AxisStatus) and Axes Group Status (AxesGroupName.Md.GroupStatus) will be "1: Stopping on error (GroupErrorStop)" and the under-control FBs will stop.

- If the acceleration/deceleration method settings are different between the under-control FB and the next FB, Acceleration/Deceleration method mismatched (error code: 1A8AH) will occur and the FBs will stop. Set the same acceleration/deceleration method in the FBs to be carried out multiple start.
- Changes are reflected at the switching of FB when a retrigger/continuous update is performed on the buffering FB after multiple start. If the warning occurs at the switching of FB, it operates with the value at multiple start without accepting the changes.

26.4 Stop

This function stops motion control.

This section describes how to stop an axis of the motion system.

Each control is stopped in the following cases.

This section describes stop processing other than when each control in the following cases is completed normally.

For operation details when a stop cause occurs in another function (such as stop processing of homing), refer to each function.

Axis operation stop

- When each control is completed normally
- When the "forced stop input" is turned off
- When the drive unit power supply is turned off
- When the drive unit network disconnection is detected
- When the drive unit error occurs
- When the forced stop is input to the drive unit
- When "Enable (Enable)" of MC_Power (Operation Available) is FALSE
- When "Servo ON request (ServoON)" of MC_Power (Operation Available) is FALSE
- When the hardware stroke limit upper/lower limit error occurs
- When a moderate or major error of the controller occurs
- When PLC READY (MotionSystem.Cd.SequenceReady) is turned off
- When the cycle over error occurs
- When a moderate error or a major error of the motion system occurs
- When the software stroke limit upper/lower limit error occurs
- When an axis error is detected
- When "Execution command (Execute)" of MC_Stop (Forced Stop) is TRUE
- When "Stop Signal (STOP)" of external input signal is TRUE

Hardware stroke limit upper/lower limit error	Software stroke limit upper/lower limit error
• FLS signal detection (at start) (error code: 1A9EH) • RLS signal detection (at start) (error code: 1A9FH) • FLS signal detection (controlling) (error code: 1AA0H) • RLS signal detection (controlling) (error code: 1AA1H)	• Software stroke limit over (forward direction) (error code: 1A83H) • Software stroke limit over (reverse direction) (error code: 1A84H)

Axes group operation stop

- When each control is completed normally
- When a stop cause occurs in the configuration axis
- When an axes group error is detected
- When "Execution command (Execute)" of MC_GroupStop (Group Forced Stop) is TRUE
- When "Stop Signal (STOP)" of external input signal is TRUE

Operation of this function for each system status

○: Available

System status	Operation availability
STOP	○
RUN	○
Moderate error	○
Major error	○

Relevant variables

Axis parameter (AxisName.Pr.)

Variable/structure name	Name	Details
StopMode_HwStrokeLimit	Stop Selection at Hardware Stroke Limit Error Occurrence	Selects operation when the hardware stroke limit upper/lower limit error occurs. • 1: Immediate Stop (ImmediateStop) (Initial value) • 2: Keep Current Acceleration/Deceleration (KeepCurrentAcc) • 3: Alternative Acceleration/Deceleration (AlternativeAcc) * Immediate stop will be executed when executing an instruction without deceleration specification.
StopMode_SwStrokeLimit	Stop Selection at Software Stroke Limit Error Occurrence	Selects operation when the software stroke limit upper/lower limit error occurs. • 1: Immediate Stop (ImmediateStop) (Initial value) • 2: Keep Current Acceleration/Deceleration (KeepCurrentAcc) • 3: Alternative Acceleration/Deceleration (AlternativeAcc) * Immediate stop will be executed when executing an instruction without deceleration specification.
StopMode_General	Stop Selection at Stop Cause Occurrence	Selects operation when a stop cause for each axis other than the stop cause 1 and 2 occurs. • 1: Immediate Stop (ImmediateStop) • 2: Keep Current Acceleration/Deceleration (KeepCurrentAcc) • 3: Alternative Acceleration/Deceleration (AlternativeAcc) (Initial value) * Immediate stop will be executed when executing an instruction without deceleration specification.
StopMode_Deceleration	Deceleration at Stop	Specifies the deceleration/deceleration time at deceleration stop by stop cause occurrence. ■When acceleration/deceleration method to specify the acceleration/deceleration • Unit: Specify with U/s^2. • Range: 0.0000, a positive number from 0.0001 to 2147483647 [U/s^2]*1 ■When acceleration/deceleration method to specify the acceleration/deceleration time • Unit: Specify with s. • Range: 0.000000, a positive number from 0.000001 to 8400.0 [s]*1 * If "0" is set, immediate stop will be executed regardless of the operation selection at start acceleration/deceleration 0 (AccelerationZeroBehavior) setting.
StopMode_DecelerationCurve	Stop Selection at Deceleration to Stop	Selects operation when a stop cause occurs during deceleration (including a stop cause and automatic deceleration). • 1: Recreate Deceleration Curve (OverrideCurve) (Initial value)
StopMode_ServoOff	Process Selection at Servo OFF Command During Operation	Selects operation when Servo ON request (ServoON) of MC_Power (Operation Available) becomes FALSE during operation. • 0: Ignore (Ignore) (Initial value) • 4: Servo OFF After Immediate Stop (ServoOffAfterImmediateStop) • 5: Servo OFF After Deceleration to Stop (ServoOffAfterDecelStop)
OverrunOperation	Operation Setting at Overrun	Selects operation when stop position is reached during deceleration stop processing by a stop cause. • 1: Immediate Stop (ImmediateStop) (Initial value) • 2: Keep Current Acceleration/Deceleration (KeepCurrentAcc)

Variable/structure name	Name	Details
StopSignal	Stop Signal	Sets a signal that uses the stop signal (STOP) of the external input signal. Stop signal (StopSignal) is a structure of SIGNAL_SELECT type. The fetch timing of the label is at Ready ON, and the detection timing of the signal is the axis operation cycle. For details on SIGNAL_SELECT type, refer to the following. ☞ Page 1156 SIGNAL_SELECT Structure It may be regarded as signal detection, depending on the variable used as an external signal and the status of devices controlled by the controller. For details, refer to the following. ☞ Page 1154 EXTERNAL SIGNAL SELECTION The specific setting and the operation of this signal are shown below. ■I/O Number (StartIO) Ignores the input value. ■Target (Target) When the specification is not set, signal disabled is determined and the signal not detecting status is always set. Only [VAR], [DEV], and [CONST] can be specified for the data type. * If an unavailable value is set, Out of parameter range (axis) (error code: 1A60H) occurs. The error cause can be checked with the following detail codes. • An incorrect string was set (detail code: 0001H) • An unavailable data type was set (detail code: 0002H) • An unavailable type was specified (detail code: 0003H) • A type other than the numerical value type was specified at label specification (detail code: 0004H) • A signal that does not exist was set (detail code: 0005H) • A global label where access from an external device is disabled was set (detail code: 0005H) • The number of characters exceeded the upper limit (detail code: 0007H). • "Asynchronous" was set in the network synchronous communication setting of the device station being referred to (detail code: 8002H) • An unsupported device was set (detail code: 8002H) • A device number out of range was set (detail code: 8002H) ■Signal Detection Method (Detection) The specification is allowed at the following level detection only. • 0: Detection at TRUE (HighLevel) • 1: Detection at FALSE (LowLevel) * When edge detection specification is set, Out of parameter range (axis) (error code: 1A60H) (detail code: 8003H) occurs. ■Compensation Time (CompensationTime) Ignores the input value. ■Filter Time (FilterTime) Setting range of the filter time is 0.0 to +5.0. * When a value outside the range is set, Out of Filter Time Setting Range of Each Axis Signal Warning (event code: 00D24H) occurs and the axis operates with 0.0 of the filter time.
StopOption_DriverTargetIgnored	Driver Command Discard Detection Setting	Select whether to detect the command discard status of the drive unit and stop with error during operation of the axis or not. • 0: FALSE Detection Disabled • 1: TRUE Detection Enabled (Initial value)

*1 Clamp by the upper limit value when the upper limit value is out of the range at stop by factors, and handle as 0 (Immediate stop) when lower limit value is out of the range.

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
StopSignal	Stop Signal	Displays the input status of the stop signal (STOP) among external input signals. Stop signal (StopSignal) is a structure of SIGNAL_SELECT type. For details on SIGNAL_SELECT type, refer to the following. ☞ Page 1156 SIGNAL_SELECT Structure The specific output of this signal is shown below. ■I/O Number (StartIO) "0" is always displayed. ■Target (Target) The fetch result of the parameter is displayed. ■Signal Detection Method (Detection) The fetch result of the parameter is displayed. ■Compensation Time (CompensationTime) "0.0" is always displayed. ■Filter Time (FilterTime) The fetch result of the parameter is displayed.
StopStatus	Stop Status	Displays the input status of the stop signal (STOP) among external input signals. • FALSE: Stop processing released • TRUE: During stop processing
StopMode_DecelerationCurve	Stop Selection at Deceleration to Stop	Displays input status of the stop processing selection at deceleration stop.
StopMode_Deceleration	Deceleration at Stop	Displays input status of the deceleration at stop.
StopMode_General	Stop Selection at Stop Cause Occurrence	Displays input status of the stop selection at stop cause occurrence.
StopMode_HwStrokeLimit	Stop Selection at Hardware Stroke Limit Error Occurrence	Displays input status of the stop selection at the hardware stroke limit error occurrence.
StopMode_ServoOff	Process Selection at Servo OFF Command During Operation	Displays input status of the processing selection at servo OFF command during operation.
StopMode_SwStrokeLimit	Stop Selection at Software Stroke Limit Error Occurrence	Displays input status of the stop selection at the software stroke limit error occurrence.
OverrunOperation	Operation Setting at Overrun	Displays the input status of the overrun operation setting.
StopOption_DriverTargetIgnored	Driver Command Discard Detection Setting	Displays driver command discard detection setting status.

Axes group parameter (AxesGroupName.Pr.)

Variable/structure name	Name	Details
StopMode_General	Stop Selection at Stop Cause Occurrence	Selects operation when a stop cause of the axes group occurs. • 1: Immediate Stop (ImmediateStop) • 2: Keep Current Acceleration/Deceleration (KeepCurrentAcc) • 3: Alternative Acceleration/Deceleration (AlternativeAcc) (Initial value) * Immediate stop will be executed when executing an instruction without deceleration specification.
StopMode_DecelerationCurve	Stop Selection at Deceleration to Stop	Selects operation when a stop cause occurs during deceleration (including a stop cause and automatic deceleration). • 1: Recreate Deceleration Curve (OverrideCurve) (Initial value)
OverrunOperation	Operation Setting at Overrun	Selects operation when stop position is reached during deceleration stop processing by a stop cause. If other than "1: Immediate Stop (ImmediateStop)" (Initial value) is set, an error will occur. • 1: Immediate Stop (ImmediateStop)
StopMode_ErrorInGroup	Configuration Axes Operation Selection at Axis Stop Cause Occurrence	During operation in the axes group, when the drive unit servo is turned off on the configuration axis and an immediate stop axis error occurs, it sets the operation of the axes on which the axis error has not occurred. • 1: Immediate Stop (ImmediateStop)
StopMode_Deceleration	Deceleration at Stop	Specifies the deceleration/deceleration time at deceleration stop by axes group stop cause occurrence. ■When acceleration/deceleration method to specify the acceleration/deceleration • Unit: Specify with U/s^2. • Range: 0.0000, a positive number from 0.0001 to 2147483647.0 [U/s^2][*1] ■When acceleration/deceleration method to specify the acceleration/deceleration time • Unit: Specify with s. • Range: 0.000000, a positive number from 0.000001 to 8400.0 [s][*1] * If "0" is set, immediate stop will be executed regardless of the operation selection at start acceleration/deceleration 0 (AccelerationZeroBehavior) setting.

*1 Clamp by the upper limit value when the upper limit value is out of the range at stop by factors, and handle as 0 (Immediate stop) when lower limit value is out of the range.

Axes group monitor data (AxesGroupName.Md.)

Variable/structure name	Name	Details
StopMode_Deceleration	Deceleration at Stop	Displays input status of the deceleration at stop.
StopMode_DecelerationCurve	Stop Selection at Deceleration to Stop	Displays input status of the stop processing selection at deceleration stop.
StopMode_ErrorInGroup	Configuration Axes Operation Selection at Axis Stop Cause Occurrence	Displays input status of the configuration axes operation selection at axis stop cause occurrence.
StopMode_General	Stop Selection at Stop Cause Occurrence	Displays input status of the stop selection at stop cause occurrence.
OverrunOperation	Operation Setting at Overrun	Displays the input status of the overrun operation setting.

System parameter (MotionSystem.Pr.)

Variable/structure name	Name	Details
StopMode_All	Stop Selection at All Axes Stop Cause Occurrence	Selects whether to stop immediately or decelerate to stop when an all axes stop cause occurs. • 1: Immediate Stop (ImmediateStop) • 2: Keep Current Acceleration/Deceleration (KeepCurrentAcc) • 3: Alternative Acceleration/Deceleration (AlternativeAcc) (Initial value) * Immediate stop will be executed when executing an instruction without deceleration specification.
StopMode_AllDeceleration	Deceleration at All Axes Stop	Specifies the deceleration/deceleration time at deceleration stop when an all axes stop cause occurred. ■When acceleration/deceleration method to specify the acceleration/deceleration • Unit: Specify with U/s^2. • Range: 0.0000, a positive number from 0.0001 to 2147483647.0 [U/s^2][*1] ■When acceleration/deceleration method to specify the acceleration/deceleration time • Unit: Specify with s. • Range: 0.000000, a positive number from 0.000001 to 8400.0 [s][*1] * If "0" is set, immediate stop will be executed regardless of the operation selection at start acceleration/deceleration 0 (AccelerationZeroBehavior) setting.

*1 Clamp by the upper limit value when the upper limit value is out of the range at stop by factors, and handle as 0 (Immediate stop) when lower limit value is out of the range.

Relevant FBs

For details on motion control FBs, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

Motion control FB	Name	Description
MC_Stop	Forced stop	Decelerates specified axis to stop.
MC_GroupStop	Group forced stop	Decelerates specified axes group to stop.

Stop cause lists

Stop causes during axis operation

The following shows stop causes during axis operation and the process when each cause occurs.

Cause No.	Stop cause	Stop axis	Axis Status (AxisName.Md.AxisStatus)		Stop process[*1]
			During deceleration stop	After stop	
1	"Forced stop input" is FALSE	Each axis/All axes	—	1: Stopping on error (ErrorStop)	Immediate Stop[*2]
2	Drive unit power supply is off	Each axis	—	1: Stopping on error (ErrorStop)	Immediate Stop[*2]
	Drive unit network disconnection detection				
	Drive unit error				
	Forced stop input to the drive unit				
	Enable (Enable) of MC_Power (Operation Available) is FALSE				
	Servo ON request (ServoON) of MC_Power (Operation Available) is FALSE (When Process Selection at Servo OFF Command During Operation (AxisName.Pr.StopMode_ServoOff) is "4: Servo OFF After Immediate Stop (ServoOffAfterImmediateStop)")[*3]				
	Drive unit control mode has switched to the control mode which the motion system axis control is not supported.				Immediate Stop[*6]
3	Hardware stroke limit upper/lower limit error occurrence	Each axis	1: Stopping on error (ErrorStop)	1: Stopping on error (ErrorStop)	Deceleration stop/immediate stop (Follows Stop Selection at Hardware Stroke Limit Error Occurrence (AxisName.Pr.StopMode_HwStrokeLimit))
4	Occurrence of a moderate or major error of the controller	All axes	1: Stopping on error (ErrorStop)	1: Stopping on error (ErrorStop)	Deceleration stop/immediate stop (Follows Stop Selection at All Axes Stop Cause Occurrence (MotionSystem.Pr.StopMode_All))[*7]
	PLC READY (MotionSystem.Cd.SequenceReady) was turned off.				
	Cycle over error occurrence[*8]				
	Moderate error or major error of the motion system occurs				
5	Software stroke limit upper/lower limit error occurrence	Each axis	1: Stopping on error (ErrorStop)	1: Stopping on error (ErrorStop)	Deceleration stop/immediate stop (Follows Stop Selection at Software Stroke Limit Error Occurrence (AxisName.Pr.StopMode_SwStrokeLimit))
6	Axis error detection[*4]	Each axis	1: Stopping on error (ErrorStop)	1: Stopping on error (ErrorStop)	Deceleration stop/immediate stop (Follows Stop Selection at Stop Cause Occurrence (AxisName.Pr.StopMode_General))
7	Execution command (Execute) of MC_Stop (Forced Stop) is TRUE	Each axis	2: Decelerating to stop (Stopping)	2: Decelerating to stop (Stopping)[*5]	Deceleration stop/immediate stop (Follows the deceleration (Deceleration) set in the FB)
8	"Stop Signal (STOP)" of external input signal is TRUE	Each axis	No change	4: Standby (Standstill)	Deceleration stop/immediate stop (Follows Stop Selection at Stop Cause Occurrence (AxisName.Pr.StopMode_General))

*1 For each operation of the stop process, refer to the following.
☞ Page 586 Stop processes for single axis

*2 The servo turns off on the drive unit side and immediate stop is performed, and also the motion system side command is stopped.

*3 Operation differs depending on the setting value selected in Process Selection at Servo OFF Command During Operation (AxisName.Pr.StopMode_ServoOff). For details, refer to the following.
☞ Page 592 Stop causes by Servo ON request (ServoON) input of MC_Power (Operation Available)

*4 If an axis error (the error that transits the status into the "1: Stopping on error (ErrorStop)" status) occurs in the buffering FB, deceleration stop will be performed from the error occurrence.

*5 When Execution command (Execute) of MC_Stop (Forced Stop) is FALSE at stop completion, Axis Status (AxisName.Md.AxisStatus) after stop will be "4: Standby (Standstill)".
*6 Immediately stops the motion system side command, and follow up on the current position.
*7 Deceleration stop may be independently performed on the drive unit side depending on the drive unit specifications. For details, check the drive unit specifications.
*8 When Cycle over (error code: 1A00H, 3402H) occurs while different operation cycles coexist, only the axis operating in the cycle over operation cycle stops.

Precautions

Provide the emergency stop circuits outside the servo system to prevent cases where danger may result from abnormal operation of the entire system in the event of an external power supply fault or servo system failure.

Stop causes during axes group operation

The following shows stop causes during axes group operation and the process when each cause occurs.

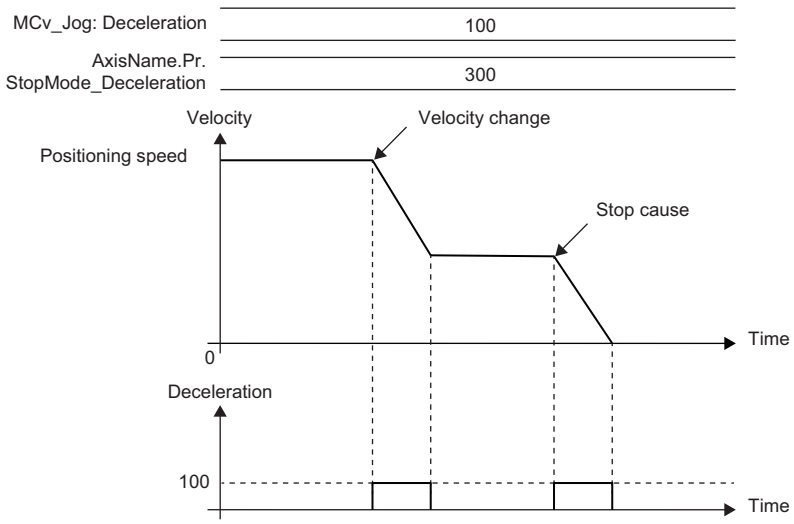
Cause No.	Stop cause		Stop axis	Axes Group Status (AxesGroupName.Md.GroupStatus)		Stop process*1	
				During deceleration stop	After stop		
1	Stop cause occurrence in the configuration axis	Axis error detection	Axes group	1: Stopping on error (GroupErrorStop)	1: Stopping on error (GroupErrorStop)	Stop cause occurrence axis	Axes group deceleration stop/immediate stop*2 (For axes group deceleration stop, it follows Stop Selection at Stop Cause Occurrence (AxesGroupName.Pr.StopMode_General).)
						Other configuration axes	Axes group deceleration stop/immediate stop (For axes group deceleration stop, it follows Stop Selection at Stop Cause Occurrence (AxesGroupName.Pr.StopMode_General).)*3
2		External input signal "Stop Signal (STOP)" is TRUE	Axes group	No change	4: Standby (GroupStandby)	Axes group deceleration stop/immediate stop (Follows Stop Selection at Stop Cause Occurrence (AxesGroupName.Pr.StopMode_General))	
3	Axes group error detection*4		Axes group	1: Stopping on error (GroupErrorStop)	1: Stopping on error (GroupErrorStop)	Axes group deceleration stop/immediate stop (Follows Stop Selection at Stop Cause Occurrence (AxesGroupName.Pr.StopMode_General))	
4	Execution command (Execute) of MC_GroupStop (Group Forced Stop) is TRUE		Axes group	2: Decelerating to stop (GroupStopping)	2: Decelerating to stop (GroupStopping)*5	Axes group deceleration stop/immediate stop (Follows the deceleration (Deceleration) set in the FB)	

*1 For each operation of the stop process, refer to the following.
☞ Page 588 Stop processes for axes group
*2 The servo turns off on the drive unit side and an immediate stop is performed, and also the motion side command is stopped.
*3 When the stop cause occurrence axis is immediately stopped by servo OFF, operation differs depending on the setting selected in Configuration Axes Operation Selection at Axis Stop Cause Occurrence (AxesGroupName.Pr.StopMode_ErrorInGroup). For details, refer to the following.
☞ Page 600 Stop cause occurrence in the configuration axis
*4 If an axes group error (the error that transits the status into the "1: Stopping on error (GroupErrorStop)" status) occurs in the FB which can be linked by the buffer mode, automatic deceleration will be performed from the axes group error occurrence.
*5 When Execution command (Execute) of MC_GroupStop (Group Forced Stop) is FALSE at stop completion, Axes Group Status (AxesGroupName.Md.GroupStatus) after stop will be "4: Standby (GroupStandby)".

Types of stop processes

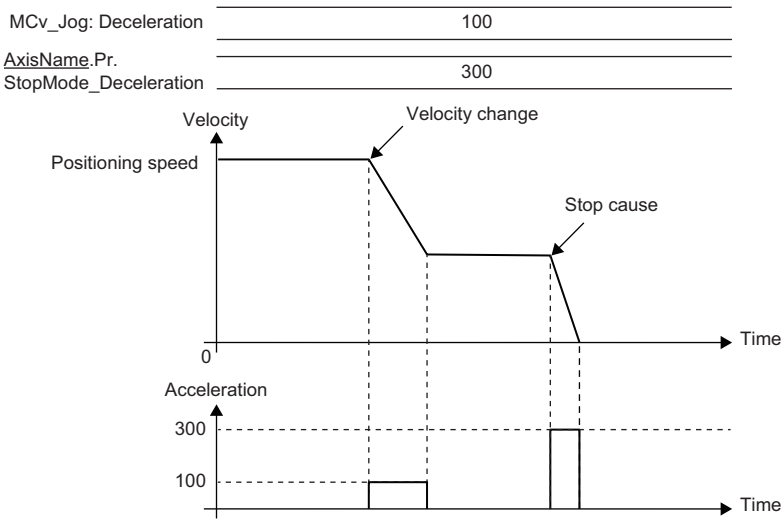
This section describes types of stop processes for a single axis and an axes group.
Stop operation by Stop Selection at Stop Cause Occurrence (AxisName(AxesGroupName).Pr.StopMode_General) and Deceleration at Stop (AxisName(AxesGroupName).Pr. StopMode_Deceleration) is explained in this section.
For the stop operation by MC_Stop (Forced Stop) or MC_GroupStop (Group Forced Stop), refer to the following.
☞ Page 596 MC_Stop (Forced Stop)
☞ Page 606 MC_GroupStop (Group Forced Stop)

Stop processes for single axis



■Deceleration stop

The operation decelerates from the speed during operation to speed 0. The deceleration differs depending on Stop Selection at Stop Cause Occurrence (AxisName.Pr.StopMode_General).

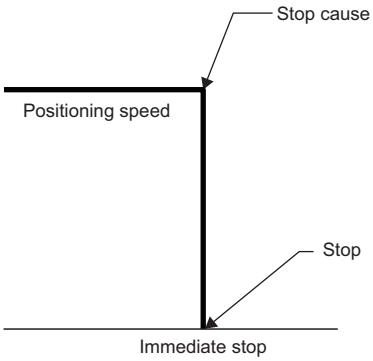


Stop Selection at Stop Cause Occurrence (AxisName.Pr.StopMode_General) setting value	Deceleration at Stop
2: Keep Current Acceleration/Deceleration (KeepCurrentAcc)	Deceleration at instruction during operation
3: Alternative Acceleration/Deceleration (AlternativeAcc)	Deceleration at Stop (AxisName.Pr. StopMode_Deceleration)

The acceleration/deceleration method and the jerk setting of deceleration stop take over the setting value of the FB which was being executed when stop cause occurred. FBs whose acceleration/deceleration method cannot be set decelerates using trapezoidal acceleration/deceleration.
For details on each stop method, refer to the following.
☞ Page 1078 Acceleration/Deceleration Processing Function

- When "2: Keep Current Acceleration/Deceleration (KeepCurrentAcc)" is set to Stop Selection at Stop Cause Occurrence (AxisName.Pr.StopMode_General) (When the instruction in operation is MCv_Jog (JOG Operation))

- When "3: Alternative Acceleration/Deceleration (AlternativeAcc)" is set to Stop Selection at Stop Cause Occurrence (AxisName.Pr.StopMode_General) (When the instruction in operation is MCv_Jog (JOG Operation))



■Immediate Stop

The operation does not decelerate and immediately stops the command.

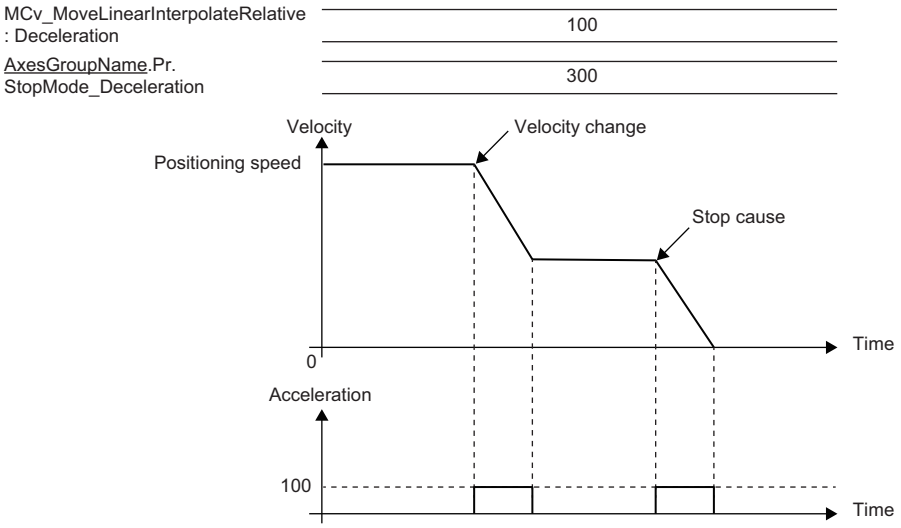
For the stop method of the drive unit, refer to each drive unit manual.

For MR-J5(W)-G: 📖MR-J5 User's Manual (Function)

Stop processes for axes group

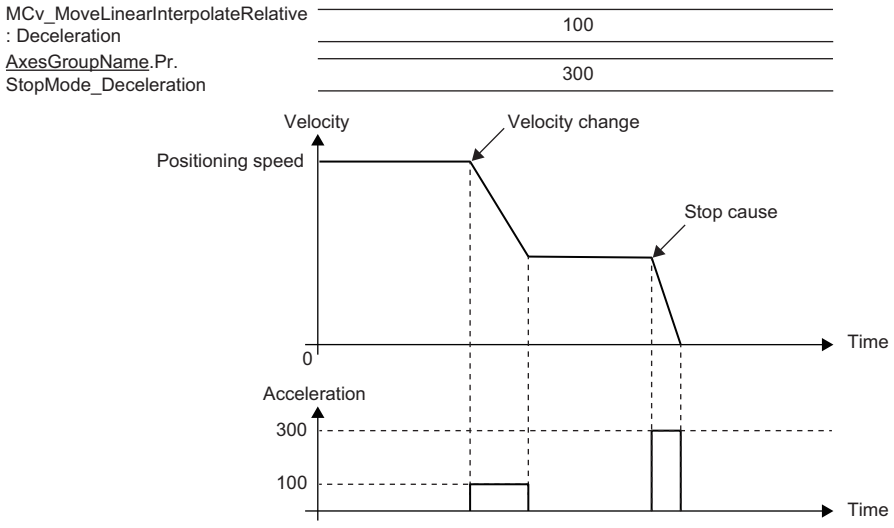
■Deceleration stop

The operation decelerates from the interpolation speed during operation to the interpolation speed 0. The deceleration differs depending on Stop Selection at Stop Cause Occurrence (AxesGroupName.Pr.StopMode_General).



Stop Selection at Stop Cause Occurrence (AxesGroupName.Pr.StopMode_General) setting value	Deceleration at Stop
2: Keep Current Acceleration/Deceleration (KeepCurrentAcc)	Deceleration at instruction during operation
3: Alternative Acceleration/Deceleration (AlternativeAcc)	Deceleration at Stop (AxesGroupName.Pr. StopMode_Deceleration)

The acceleration/deceleration method and the jerk setting of deceleration stop take over the setting value of the FB which was being executed when stop cause occurred.

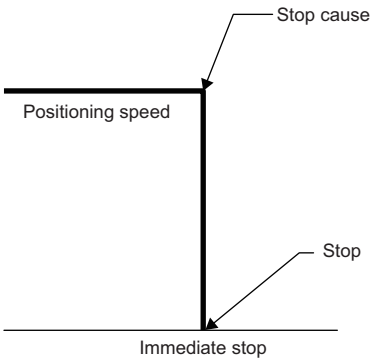


For specifications of each stop method, refer to the following.

☞ Page 1078 Acceleration/Deceleration Processing Function

- When "2: Keep Current Acceleration/Deceleration (KeepCurrentAcc)" is set to Stop Selection at Stop Cause Occurrence (AxesGroupName.Pr.StopMode_General) (When the instruction in operation is MCv_MoveLinearInterpolateRelative (Relative Value Linear Interpolation Control))

- When "3: Alternative Acceleration/Deceleration (AlternativeAcc)" is set to Stop Selection at Stop Cause Occurrence (AxesGroupName.Pr.StopMode_General) (When the instruction in operation is MCv_MoveLinearInterpolateRelative (Relative Value Linear Interpolation Control))



■Immediate Stop

The operation does not decelerate and immediately stops the command of the configuration axis.

For the stop method of the drive unit, refer to each drive unit manual.

For MR-J5(W)-G: MR-J5 User's Manual (Function)

Order of priority for stop process

This section describes the processes when multiple stop causes occur.

The order of priority is as shown below based on the stop process of occurred stop cause.

Priority	Stop method
1	Immediate stop
2	Deceleration stop

When a deceleration stop cause occurs again during deceleration stop (including a stop cause and automatic deceleration), the deceleration process differs depending on the following parameter settings for a single axis or an axes group.

Item	Parameter	Setting value
Single axis	Stop Selection at Deceleration to Stop (AxisName.Pr.StopMode_DecelerationCurve)	1: Recreate Deceleration Curve (OverrideCurve)
Axes group	Stop Selection at Deceleration to Stop (AxesGroupName.Pr.StopMode_DecelerationCurve)	

Deceleration curve re-processing

■1: Recreate Deceleration Curve (OverrideCurve)

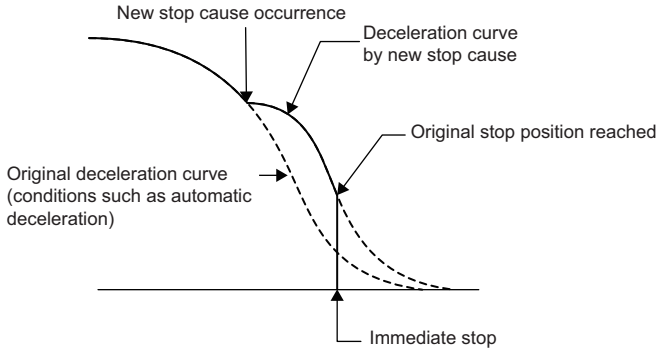
A deceleration curve is re-processed from the deceleration of the new stop cause.

During single axis operation, the stop position can be overrun depending on the deceleration and the jerk setting. To avoid overrun, set "1: Immediate Stop (ImmediateStop)" in Operation Setting at Overrun (AxisName.Pr.OverrunOperation).

For operation details, refer to the following.

☞ Page 591 Overrun at stop cause occurrence

Overrun at stop cause occurrence

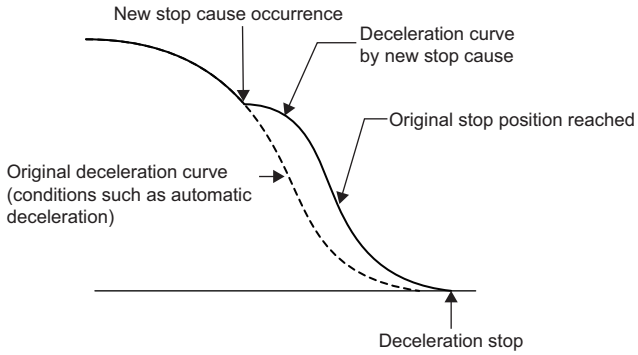


This function selects operation for the case that the positioning address of an instruction which was executed before a stop cause occurs is reached during deceleration stop and immediate stop process.
This function is enabled only when the target position exists at stop cause occurrence.
The following parameters for a single axis or an axes group need to be set in this function.

Item	Parameter	Setting value
Single axis	Operation Setting at Overrun (AxisName.Pr.OverrunOperation)	1: Immediate Stop (ImmediateStop) 2: Keep Current Acceleration/Deceleration (KeepCurrentAcc)
Axes group	Operation Setting at Overrun (AxesGroupName.Pr.OverrunOperation)	1: Immediate Stop (ImmediateStop)

Immediate Stop

■1: Immediate Stop (ImmediateStop)



The operation is immediately stopped when reaching the original positioning address during deceleration by a stop cause. In this case, the operation does not exceed the positioning address set in the under-control FB.

Keep current acceleration/deceleration (Only for a single axis)

■2: Keep Current Acceleration/Deceleration (KeepCurrentAcc)

Deceleration continues even though the operation reached the original deceleration stop position during deceleration by a stop cause. In this case, there is no guarantee that it stops before the positioning address set in the under-control FB.

Stop during single axis operation

This section describes each stop cause.

Stop causes of immediate stop with no condition

When the following stop causes occur, the servo OFF is executed in the drive unit and the axis stops immediately.
For how to stop the drive unit, refer to each drive unit manual.
For MR-J5(W)-G: 📖MR-J5 User's Manual (Function)

- "Forced stop input" is turned off from an external device.*1
- Drive unit power supply OFF
- Drive unit network disconnection detection
- Drive unit error
- Forced stop input to the drive unit
- "Enable (Enable)" of MC_Power (Operation Available) is FALSE

*1 The forced stop input is set in Forced Stop Signal (AxisName.Pr.ForcedStop_Signal). For operation details, refer to the following.
☞ Page 609 Forced Stop

Stop causes by Servo ON request (ServoON) input of MC_Power (Operation Available)

■Process selection at servo OFF command during operation

When Servo ON request (ServoON) of MC_Power (Operation Available) is set to FALSE, the stop operation differs depending on the setting of Process Selection at Servo OFF Command During Operation (AxisName.Pr.StopMode_ServoOff). Process Selection at Servo OFF Command During Operation (AxisName.Pr.StopMode_ServoOff) has the following three functions.

Process Selection at Servo OFF Command During Operation (AxisName.Pr.StopMode_ServoOff)*1	Description
0: Ignore (Ignore)	During operation, this function ignores the servo OFF command even though it is input and continues on-going operation. If Servo ON request (ServoON) of MC_Power (Operation Available) is set to FALSE when Axis Status (AxisName.Md.AxisStatus) of the operation completion axis turns to "4: Standby (Standstill)", servo OFF will be executed. (The axis will not stop.)
4: Servo OFF After Immediate Stop (ServoOffAfterImmediateStop)	During operation, the command is immediately stopped by Immediate stop by servo OFF (error code: 1AAAH), and a servo OFF is issued to the drive unit.
5: Servo OFF After Deceleration to Stop (ServoOffAfterDecelStop)	During operation, when receiving the servo OFF command input, Deceleration stop by servo OFF during operation (error code: 1AA9H) occurs and deceleration stop is executed. If Servo ON request (ServoON) of MC_Power (Operation Available) is FALSE when the operation has reached speed 0, servo OFF will be executed.

*1 The axis type which does not have Process Selection at Servo OFF Command During Operation (AxisName.Pr.StopMode_ServoOff) operates "4: Servo OFF After Immediate Stop (ServoOffAfterImmediateStop)".

■Axis state transition

The axis state changes based on the input combination of Enable (Enable) and Servo ON request (ServoON) of MC_Power (Operation Available).

Axis status before input operation (AxisName.Md.AxisStatus)	Input		Process Selection at Servo OFF Command During Operation (AxisName.Pr.StopMode_ServoOff)	Axis Status (AxisName.Md.AxisStatus) after input operation
	Enable (Enable)	Servo ON request (ServoON)		
4: Standby (Standstill) 0: Axis disabled (Disabled)	TRUE	TRUE	Independent of the setting	4: Standby (Standstill)
		FALSE		0: Axis disabled (Disabled)
	FALSE	TRUE		
		FALSE		
1: Stopping on error (ErrorStop)	TRUE	TRUE		1: Stopping on error (ErrorStop)
		FALSE		
	FALSE	TRUE		
		FALSE		
Others	TRUE	TRUE		No transition
		FALSE	0: Ignore (Ignore)	No transition*1*2
			4: Servo OFF After Immediate Stop (ServoOffAfterImmediateStop)	1: Stopping on error (ErrorStop)*4
			5: Servo OFF After Deceleration to Stop (ServoOffAfterDecelStop)	1: Stopping on error (ErrorStop)*3
	FALSE	TRUE	Independent of the setting	1: Stopping on error (ErrorStop)*4
		FALSE		

*1 It is "0: Axis disabled (Disabled)" when Axis Status (AxisName.Md.AxisStatus) is "4: Standby (Standstill)" or "2: Decelerating to stop (Stopping)" after deceleration stop.

*2 Axis Status (AxisName.Md.AxisStatus) will not transit if Axis Status (AxisName.Md.AxisStatus) is "1: Stopping on error (ErrorStop)" after deceleration stop.

*3 If Servo ON request (ServoON) becomes FALSE during operation, Deceleration stop by servo OFF during operation (error code: 1AA9H) will occur.

*4 When Enable (Enable)/Servo ON request (ServoON) becomes FALSE, Immediate stop by servo OFF during operation (error code: 1AAAH) occurs. In this case, the under-control FB will be completed or stop immediately, and servo OFF will be executed.

Hardware stroke limit upper/lower limit error occurrence

When the hardware stroke limit upper/lower limit error occurs, the operation stops according to the process selected by Stop Selection at Hardware Stroke Limit Error Occurrence (AxisName.Pr.StopMode_HwStrokeLimit).

For details, refer to the following.

☞ Page 1069 Hardware Stroke Limit

Occurrence of a moderate or major error of the controller

When the stop error occurs in the control CPU module, PLC READY (MotionSystem.Cd.SequenceReady) holds on, and the motion side will be STOP status.

PLC Ready (MotionSystem.Cd.SequenceReady) off

When the PLC READY (MotionSystem.Cd.SequenceReady) is turned off, the operation stops according to the process selected by Stop Selection at All Axes Stop Cause Occurrence (MotionSystem.Pr.StopMode_All).

Cycle over error occurrence

When the cycle over error occurs in operation cycle processing, the operation stops according to the process selected by Stop Selection at All Axes Stop Cause Occurrence (MotionSystem.Pr.StopMode_All).

According to the set values of Cycle Setting (MotionSystem.PrConst.OperationCycle[].CycleOverErrorType), a different error code is output in every axis.

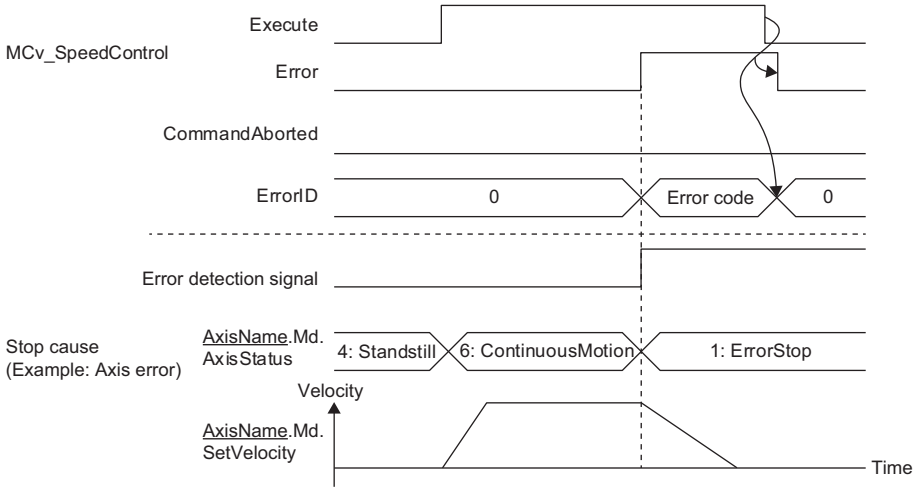
Cycle over error assignment selection	System error code to be output	Axis error code to be output
2: Minor Error (MinorError)	Cycle over (error code: 1A00H)	Cycle over (error code: 1A00H)
3: Moderate Error (ModerateError)	Cycle over (error code: 3402H)	Module error during operation (error code: 1B00H)*1

*1 It causes the operation stop as the stop cause at the motion system moderate error or major error occurrence.

Software stroke limit upper/lower limit error occurrence

When the software stroke limit upper/lower limit error occurs, the operation stops according to the process selected by Stop Selection at Software Stroke Limit Error Occurrence (AxisName.Pr.StopMode_SwStrokeLimit).

For details, refer to the following.



☞ Page 1061 Software Stroke Limit

Axis error detection

When an axis error other than the errors below is detected, the operation stops according to the process selected by Stop Selection at Stop Cause Occurrence (AxisName.Pr.StopMode_General). In this case, Axis Status (AxisName.Md.AxisStatus) transits to "1: Stopping on error (ErrorStop)".

- Hardware stroke limit upper/lower limit error
- Controller error
- PLC READY (MotionSystem.Cd.SequenceReady) OFF error
- Cycle over (error code: 1A00H, 3402H)
- Software stroke limit upper/lower limit error
- Drive unit error

- Operation of the FB that received a stop cause by axis error occurrence

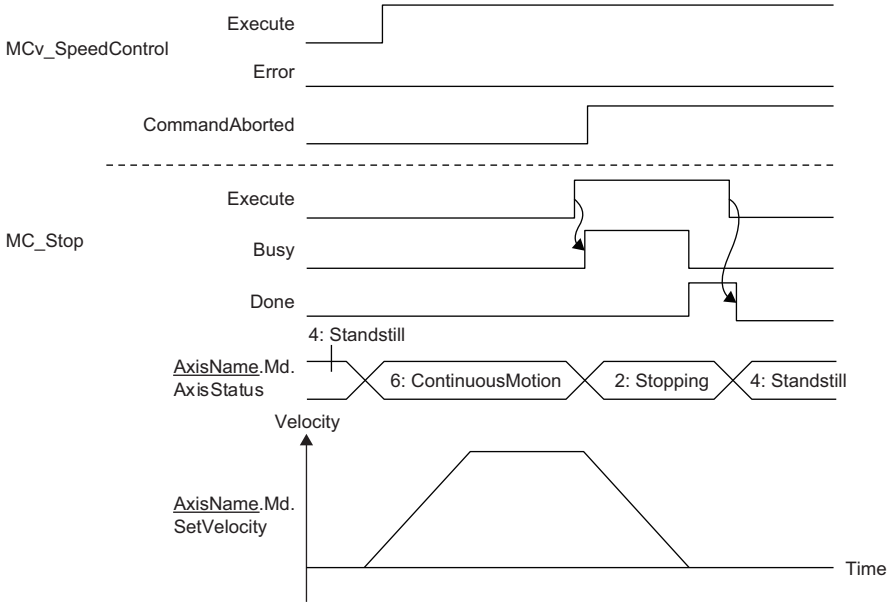
■Driver command discard detection

This function stops commands from the motion system in response to detection operations such as limit detection or forced stop of the drive unit.

In the drive unit, when a command received from the motion system is discarded and operation continues, such as when limit detection or a forced stop occurs, Statusword (Bit 12) changes from on to off. At this time, if the controller is operating a real drive axis, it will output Driver command discard detection (error code: 1B18H) and stop the command.

Point

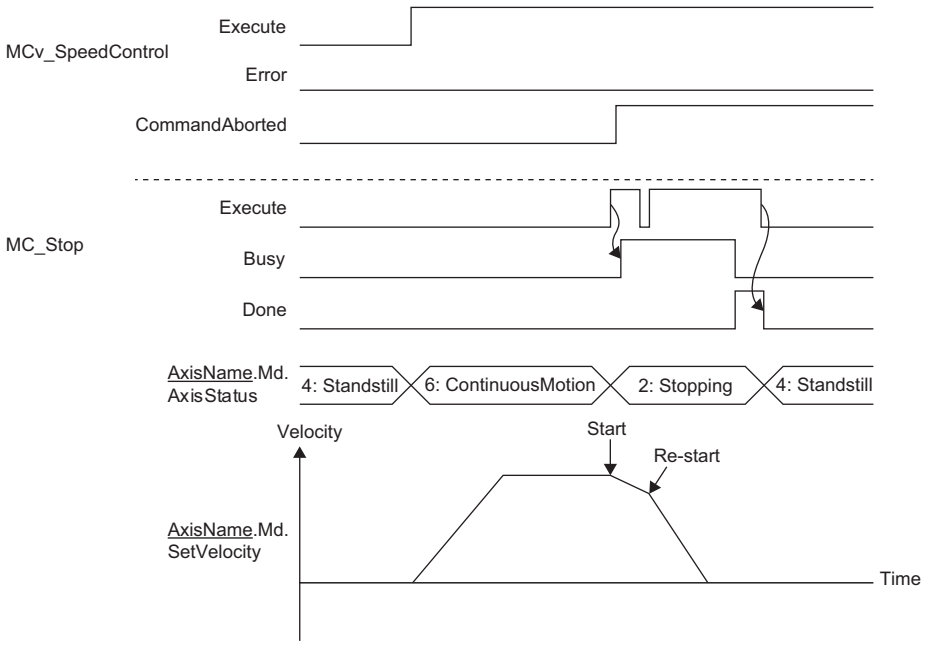
Before or after Driver command discard detection (error code: 1B18H) occurs, an alarm that caused the command to be discarded may occur in the drive unit. If a drive unit alarm occurs, perform troubleshooting according to the drive unit manual.



Driver command discard detection can be enabled or disabled for each axis by setting Driver Command Discard Detection Setting (AxisName.Pr.StopOption_DriverTargetIgnored). (Initial state: Enabled)

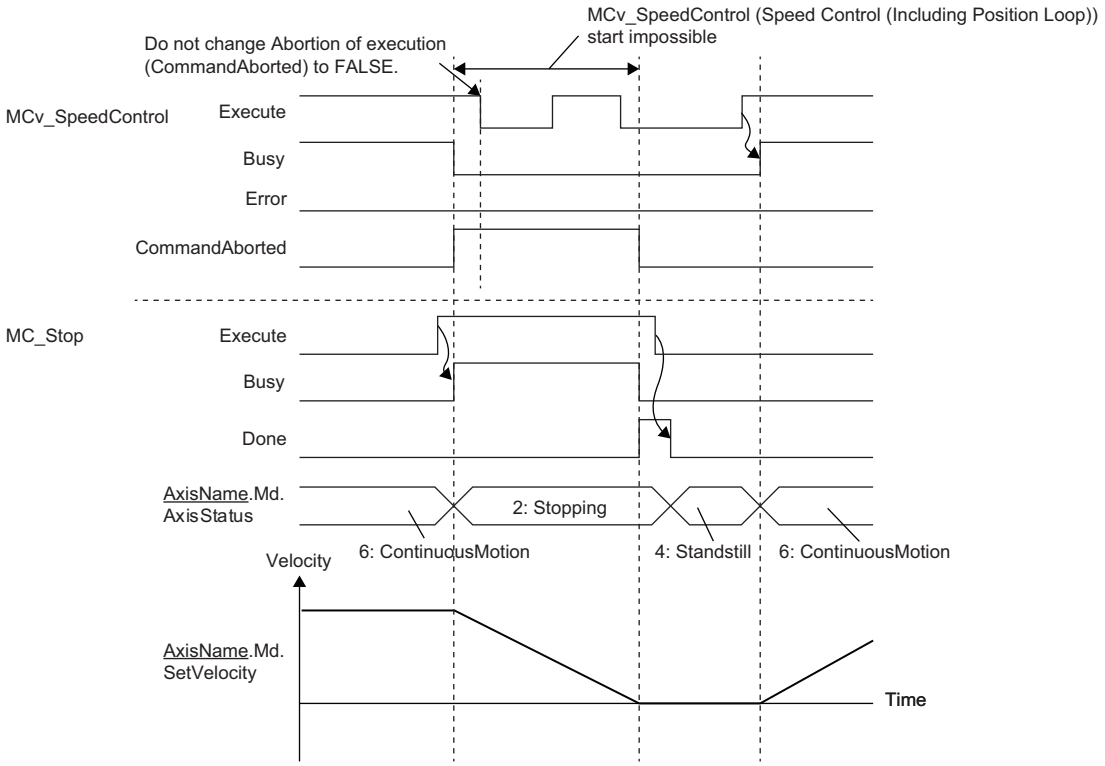
If Driver Command Discard Detection Setting is disabled, commands from the motion system will continue regardless of Statusword (Bit12). Also, Driver command discard detection (error code: 1B18H) is not detected.

MC_Stop (Forced Stop)



In MC_Stop (Forced Stop), Deceleration (Deceleration) is set and the under-control FB is decelerated to stop.
When MC_Stop (Forced Stop) is executed, Abortion of execution (CommandAborted) of the on-going FB becomes TRUE and Axis Status (AxisName.Md.AxisStatus) transits to the "2: Decelerating to stop (Stopping)" status. While Execution command (Execute) is TRUE or while the speed does not reach 0.0, the "2: Decelerating to stop (Stopping)" status is maintained. When Execution completion (Done) becomes TRUE and Execution command (Execute) becomes FALSE at stop completion, the axis status changes to the "4: Standby (Standstill)" status.

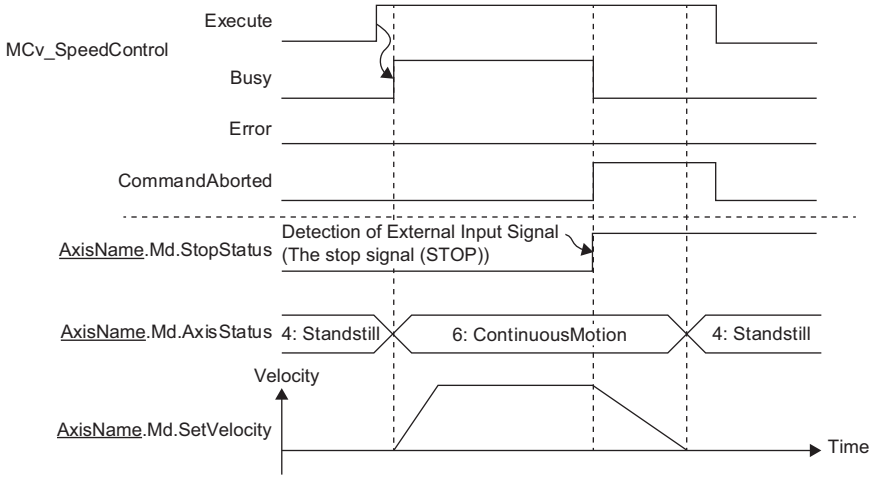
■MCv_Stop (Forced Stop) execution during MC_SpeedControl (Speed Control (Including Position Loop))



■Operation description

- During deceleration to stop by this FB and while Execution command (Execute) of the input variable is TRUE, any operation command other than MC_Stop (Forced Stop) is not accepted.
- If the deceleration is set to 0.0 or omitted, immediate stop will be executed.
- The acceleration/deceleration method and the jerk take over the method specified in the control being executed and deceleration is performed.
- If MC_GroupStop (Group Forced Stop) is executed during single axis synchronous control, synchronization to the master axis will be canceled.
- When the setting value of Deceleration (Deceleration) is changed and MC_Stop (Forced Stop) is restarted, deceleration stop is executed from the restart point based on Deceleration (Deceleration) set in MC_Stop (Forced Stop).

- When an FB that operates axes other than MC_Stop (Forced Stop) is executed while Axis Status (AxisName.Md.AxisStatus) is the "2: Decelerating to stop (Stopping)" status, Start not possible (error code: 1AFCH) occurs and Error of MC_Stop (Forced Stop) becomes TRUE, and then Axis Status (AxisName.Md.AxisStatus) changes to "1: Stopping on error (ErrorStop)".
- After the axis stops, the axis status can be transited to "4: Standby (Standstill)" by executing Axis Error Reset (AxisName.Cd.ErrorReset).
- Even if Execution command (Execute) of command aborted FB by MC_Stop (Forced Stop) set to FALSE, once the stop operation is started, TRUE of Abortion of execution (CommandAborted) will be continued until it is completed. After it stops completely, Abortion of execution (CommandAborted) is changed to FALSE if Execution command (Execute) of command aborted FB is FALSE.



"Stop Signal (STOP)" of external input signal is TRUE

The under-control FB is stopped by setting the stop signal (STOP) set by Stop Signal (AxisName.Pr.StopSignal) to TRUE.

- The operation stops by the operation set in Stop Selection at Stop Cause Occurrence (AxisName.Pr.StopMode_General).
- The under-control FB sets Abortion of execution (CommandAborted) to TRUE by changing the stop signal (STOP) to TRUE.

  When the speed reaches 0, Axis Status (AxisName.Md.AxisStatus) transits to "4: Standby (Standstill)".

Point

- When the process is stopped by TRUE of Stop Signal (AxisName.Pr.StopSignal), Axis Status (AxisName.Md.AxisStatus) after stop will not change.
- The deceleration can be changed by executing MC_Stop (Forced Stop) while the stop processing is executed by TRUE of Stop Signal (AxisName.Pr.StopSignal).
- The deceleration can be changed when Stop Signal (AxisName.Pr.StopSignal) is TRUE during MC_Stop (Forced Stop) execution. In this case, Axis Status (AxisName.Md.AxisStatus) after deceleration stop will not change.

- Even if Execution command (Execute) of command aborted FB is set to FALSE by changing the stop signal (STOP) to TRUE, once the stop operation is started, TRUE of Abortion of execution (CommandAborted) will be continued until it is completed. After it stops completely, Abortion of execution (CommandAborted) is changed to FALSE if Execution command (Execute) of command aborted FB is FALSE.

Stop during axes group operation

This section describes each stop cause.

Stop cause occurrence in the configuration axis

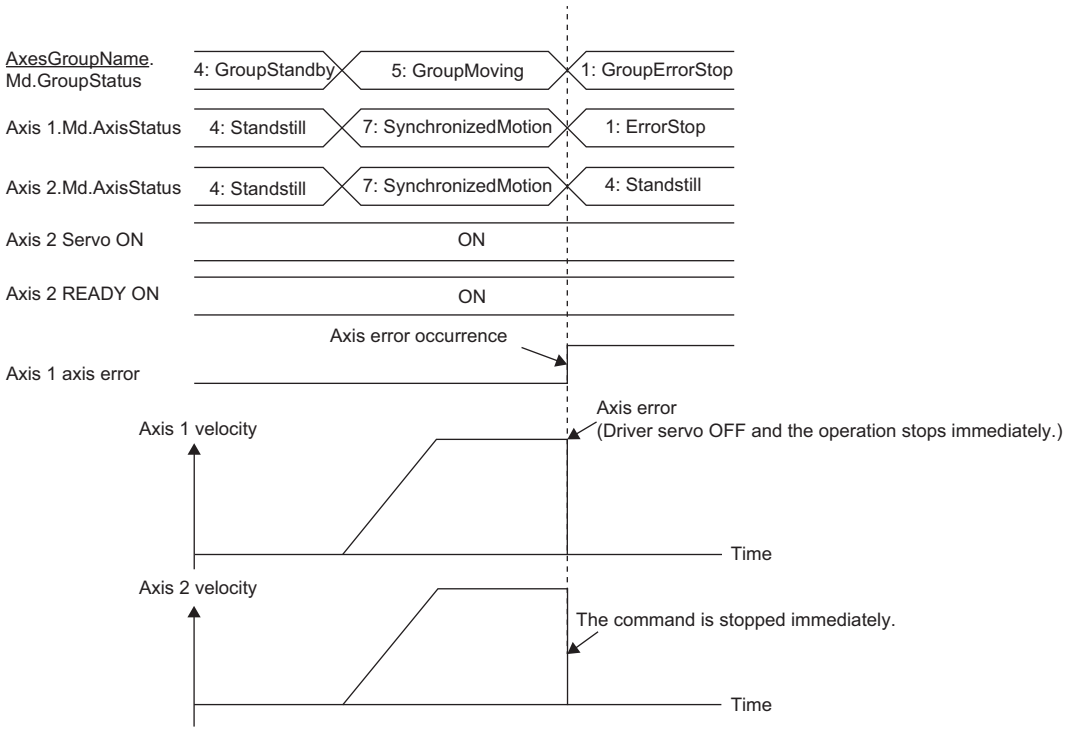
The following describes the axes group operation when a stop cause of the configuration axis occurs.

Stop cause occurrence axis				Axes group	
Cause No.	**Stop cause**	**Axis Status (AxisName.Md.AxisStatus) at stop cause occurrence**	**Stop process**	**Axes Group Status (AxesGroupName.Md.GroupStatus)**	**Stop process**
1	"Forced stop input" is off	1: Stopping on error (ErrorStop)	Immediate Stop*1	1: Stopping on error (GroupErrorStop)	■Stop cause occurrence axis Immediate stop ■Other configuration axes Axes group deceleration stop/immediate stop (Follows Configuration Axes Operation Selection at Axis Stop Cause Occurrence (AxesGroupName.Pr.StopMode_ErrorInGroup))
2	Drive unit power supply is off	1: Stopping on error (ErrorStop)			
	Drive unit network disconnection detection				
	Drive unit error				
	Forced stop input to the drive unit				
	Enable (Enable) of MC_Power (Operation Available) is FALSE				
	Servo ON request (ServoON) of MC_Power (Operation Available) is FALSE (When Process Selection at Servo OFF Command During Operation (AxisName.Pr.StopMode_ServoOff) is "4: Servo OFF After Immediate Stop (ServoOffAfterImmediateStop)")				

Stop cause occurrence axis				Axes group	
Cause No.	**Stop cause**	**Axis Status (AxisName.Md.AxisStatus) at stop cause occurrence**	**Stop process**	**Axes Group Status (AxesGroupName.Md.GroupStatus)**	**Stop process**
3	Hardware stroke limit upper/lower limit error occurrence in the configuration axis	1: Stopping on error (ErrorStop)	Based on the axes group stop process	1: Stopping on error (GroupErrorStop)	Operation differs depending on the setting value of Stop Selection at Hardware Stroke Limit Error Occurrence (AxisName.Pr.StopMode_HwStrokeLimit) of the configuration axis. ■When the configuration axis has an axis set to "1: Immediate Stop (ImmediateStop)": Immediate Stop ■When the configuration axis does not have an axis set to "1: Immediate Stop (ImmediateStop)" Axes group deceleration stop/immediate stop (Follows Stop Selection at Stop Cause Occurrence (AxesGroupName.Pr.StopMode_General))
4	Occurrence of a moderate or major error of the controller	1: Stopping on error (ErrorStop)			Axes group deceleration stop/immediate stop (Follows Stop Selection at Stop Cause Occurrence (AxesGroupName.Pr.StopMode_General))
	PLC READY (MotionSystem.Cd.SequenceReady) is off.				
	Cycle over error occurrence				
5	Software stroke limit upper/lower limit error occurrence in the configuration axis	1: Stopping on error (ErrorStop)			Operation differs depending on the setting value of Stop Selection at Software Stroke Limit Error Occurrence (AxisName.Pr.StopMode_SwStrokeLimit) of the configuration axis. ■When the configuration axis has an axis set to "1: Immediate Stop (ImmediateStop)": Immediate Stop ■When the configuration axis does not have an axis set to "1: Immediate Stop (ImmediateStop)" Axes group deceleration stop/immediate stop (Follows Stop Selection at Stop Cause Occurrence (AxesGroupName.Pr.StopMode_General))
6	Axis error detection	1: Stopping on error (ErrorStop)			Axes group deceleration stop/immediate stop (Follows Stop Selection at Stop Cause Occurrence (AxesGroupName.Pr.StopMode_General))
7	Execution command (Execute) of MC_Stop (Forced Stop) is TRUE	1: Stopping on error (ErrorStop)*2			
8	"Stop Signal (STOP)" of external input signal is TRUE	No change		No change	

*1 The servo turns off on the drive unit side and an immediate stop is performed, and also the motion side command is stopped.

*2 If a single axis FB is executed during axes group operation, an axis error will occur and the single axis FB will be disabled. For details, refer to the following.



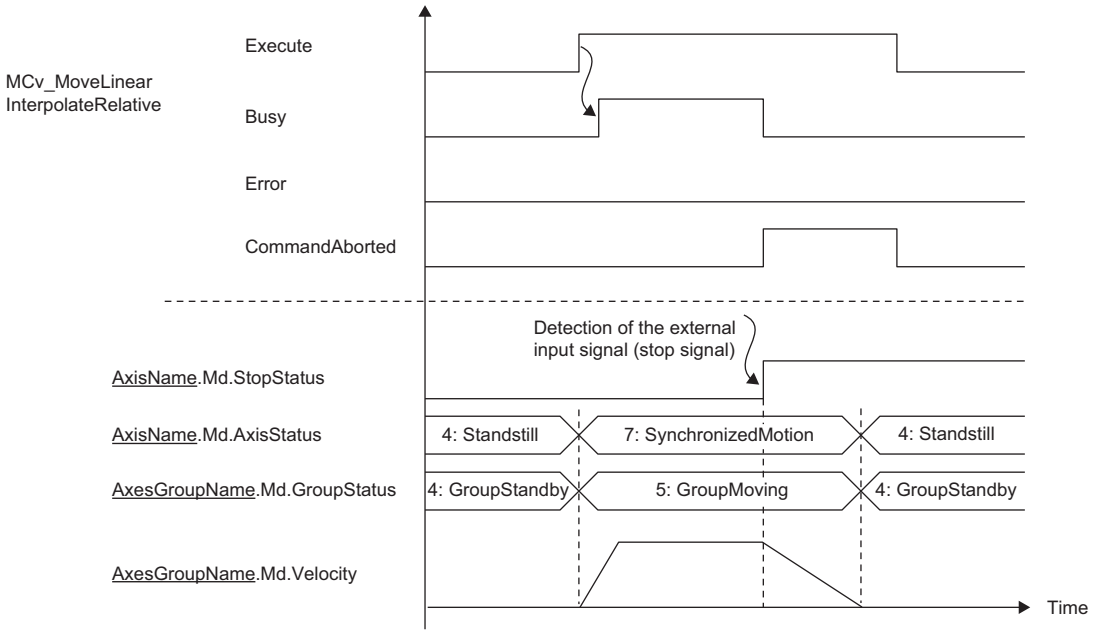
☞ Page 603 Axis error

When a stop cause has occurred in a configuration axis of the axes group, operation differs depending on the following four patterns.

■For an axis error (drive unit servo OFF and immediate stop)

Stop Cause of Axes group configuration axis (error code: 1AABH) occurs in the axes group.
Also, if the drive unit of the configuration axis on which the stop cause occurred turns the servo off and stops immediately, the other configuration axis will follow the stop process selected in Configuration Axes Operation Selection at Axis Stop Cause Occurrence (AxesGroupName.Pr.StopMode_ErrorInGroup).
When a stop cause has occurred in a configuration axis during the axes group operation, the following methods show how to stop the other configuration axes.

- Immediate Stop (ImmediateStop)
  In the axes group configuration axes other than the axis which an axis error has occurred in, a command to the drive unit is stopped.

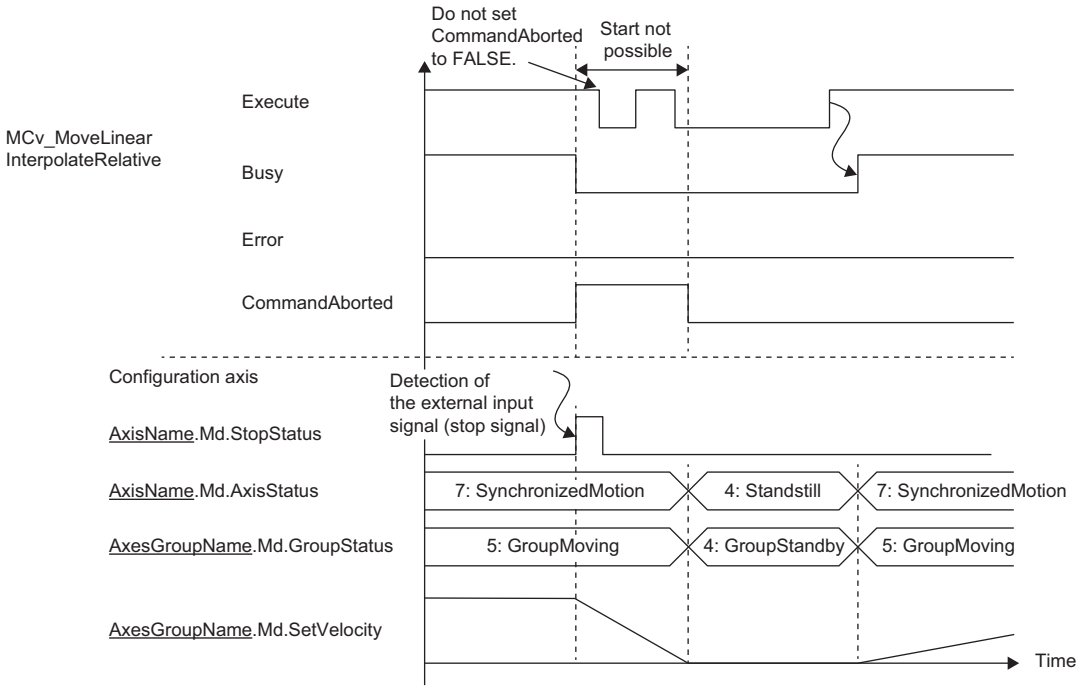


■Axis error

If an axis error has occurred in the configuration axis, Stop cause of axes group configuration axis (error code: 1AABH) will occur in the axes group. In this case, the axes group will pass through the path and stop according to the setting of Stop Selection at Stop Cause Occurrence (AxesGroupName.Pr.StopMode_General).
If a single axis control FB is executed to the configuration axis being operated in the axes group, an error will occur in the single axis control FB and Start not possible (error code: 1AFCH) or Motion FB issue error to the axis during axes group operating (error code: 1AE2H) will occur on the specified axis, resulting in the "1: Stopping on error (ErrorStop)" status.
By an error occurrence in the configuration axis, Stop cause of axes group configuration axis (error code: 1AABH) occurs in the axes group, and the axes group will stop according to the process selected in Stop Selection at Stop Cause Occurrence (AxesGroupName.Pr.StopMode_General).

■"Stop Signal (STOP)" of external input signal is TRUE

The under-control FB is stopped by setting Stop Signal (AxisName.Pr.StopSignal) to TRUE for any of the configuration axes.



- The operation stops by the operation set in Stop Selection at Stop Cause Occurrence (AxesGroupName.Pr.StopMode_General).
- The axes group will pass through the path and decelerate to a stop.
- The under-control FB sets Abortion of execution (CommandAborted) to TRUE by changing Stop Signal (AxisName.Pr.StopSignal) to TRUE.
- When the speed reaches 0, Axes Group Status (AxesGroupName.Md.GroupStatus) will transit to "4: Standby (GroupStandby)". The value set in Deceleration at Stop (AxesGroupName.Pr.StopMode_Deceleration) will be used for the deceleration at this time.

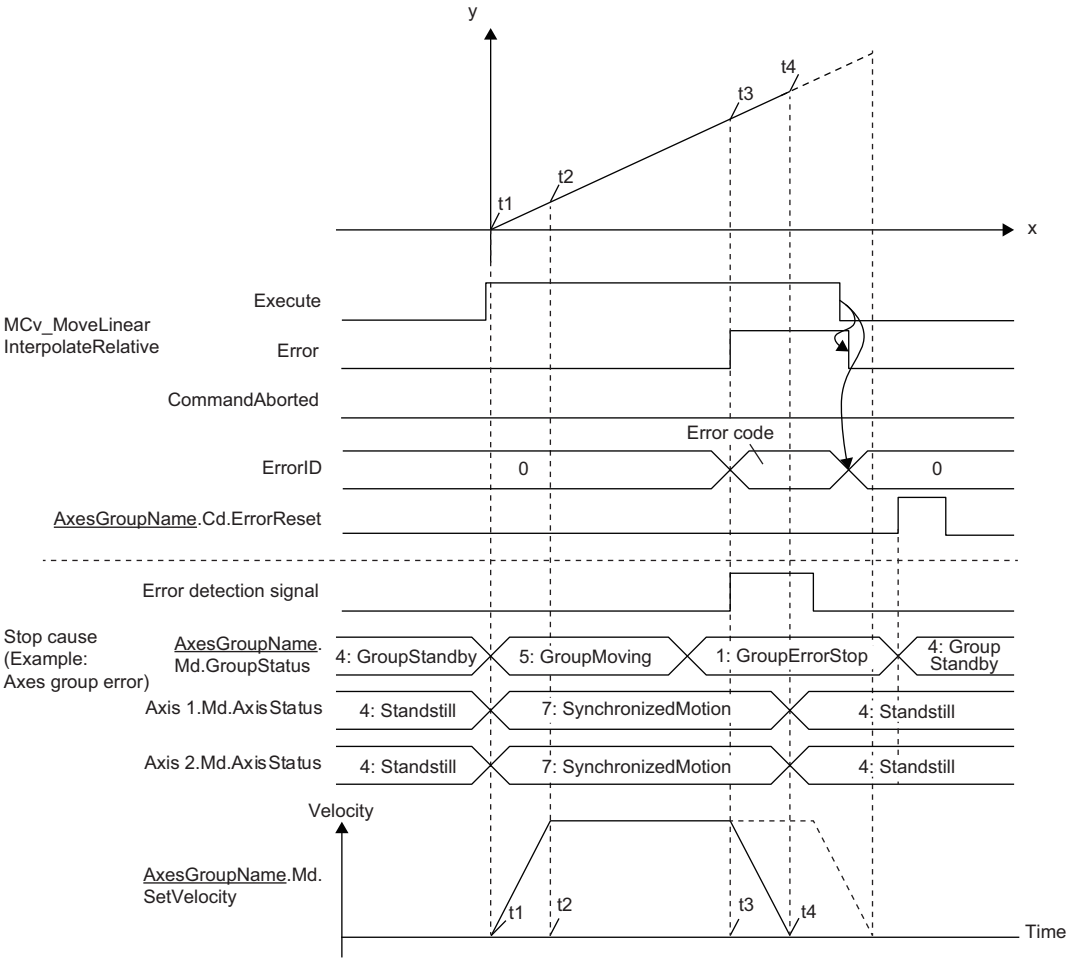
Point

- When stopping by setting Stop Signal (AxisName.Pr.StopSignal) to TRUE, Axes Group Status (AxesGroupName.Md.GroupStatus) after stop will not change.
- When the stop processing is being executed by setting Stop Signal (AxisName.Pr.StopSignal) to TRUE, the deceleration can be changed by executing MC_GroupStop (Group Forced Stop).
- The deceleration can be changed by setting Stop Signal (AxisName.Pr.StopSignal) to TRUE during MC_GroupStop (Group Forced Stop) execution. In this case, Axes Group Status (AxesGroupName.Md.GroupStatus) after the deceleration stop will not change.

- Even if Execution command (Execute) of command aborted FB is set to FALSE by changing Stop Signal (AxisName.Pr.StopSignal) to TRUE, once the stop operation is started, TRUE of Abortion of execution (CommandAborted) will be continued until it is completed. After it stops completely, Abortion of execution (CommandAborted) is changed to FALSE if Execution command (Execute) of command aborted FB is FALSE.

■Hardware stroke limit error/Software stroke limit error

When any of the following conditions is satisfied, the axes group will immediately stop regardless of the axes group setting. In this case, Stop cause of axes group configuration axis (error code: 1AABH) occurs in the axes group and its status changes to "1: Stopping on error (GroupErrorStop)".



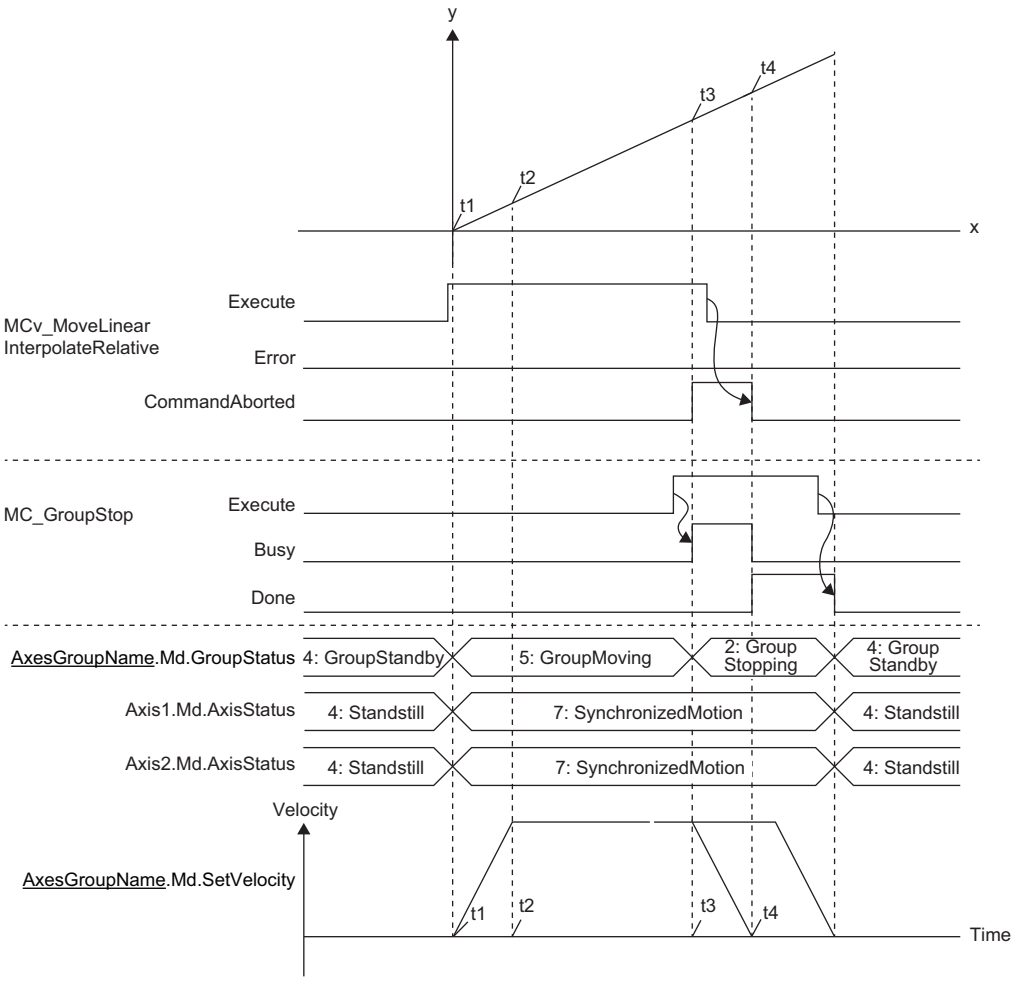
- When the stop cause "Hardware stroke limit error" is occurring in any axis of configuration axes, "1: Immediate Stop (ImmediateStop)" is set to Stop Selection at Hardware Stroke Limit Error Occurrence (AxisName.Pr.StopMode_HwStrokeLimit) in one or more axes.
- When the stop cause "Software stroke limit error" is occurring in any axis of configuration axes, "1: Immediate Stop (ImmediateStop)" is set to Stop Selection at Software Stroke Limit Error Occurrence (AxisName.Pr.StopMode_SwStrokeLimit) in one or more axes.

Hardware stroke limit error	Software stroke limit error
• FLS signal detection (at start) (error code: 1A9EH) • RLS signal detection (at start) (error code: 1A9FH) • FLS signal detection (controlling) (error code: 1AA0H) • RLS signal detection (controlling) (error code: 1AA1H)	• Software stroke limit over (target position) (error code: 1A80H) • Software stroke limit over (start position) (error code: 1A81H) • Software stroke limit over (forward direction) (error code: 1A83H) • Software stroke limit over (reverse direction) (error code: 1A84H)

Axes group error detection

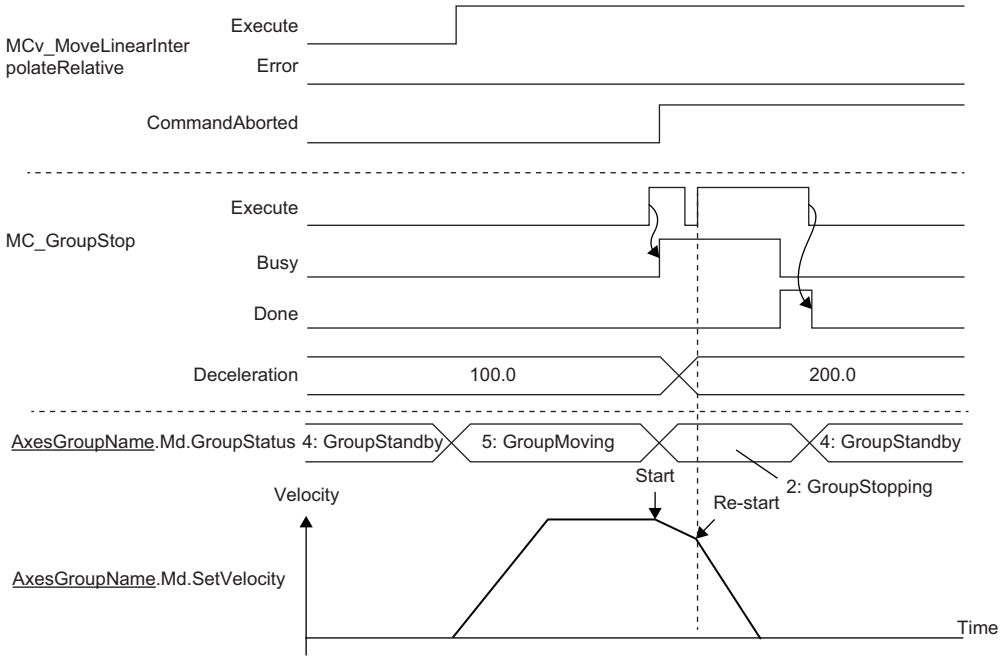
When an axes group error other than the "Stop cause occurrence in the configuration axis" is detected, the operation will be stopped according to the process selected by Stop Selection at Stop Cause Occurrence (AxesGroupName.Pr.StopMode_General). The value set in Deceleration at Stop (AxesGroupName.Pr.StopMode_Deceleration) will be used for the deceleration at this time.

• Operation of the FB that received a stop cause by axes group error occurrence



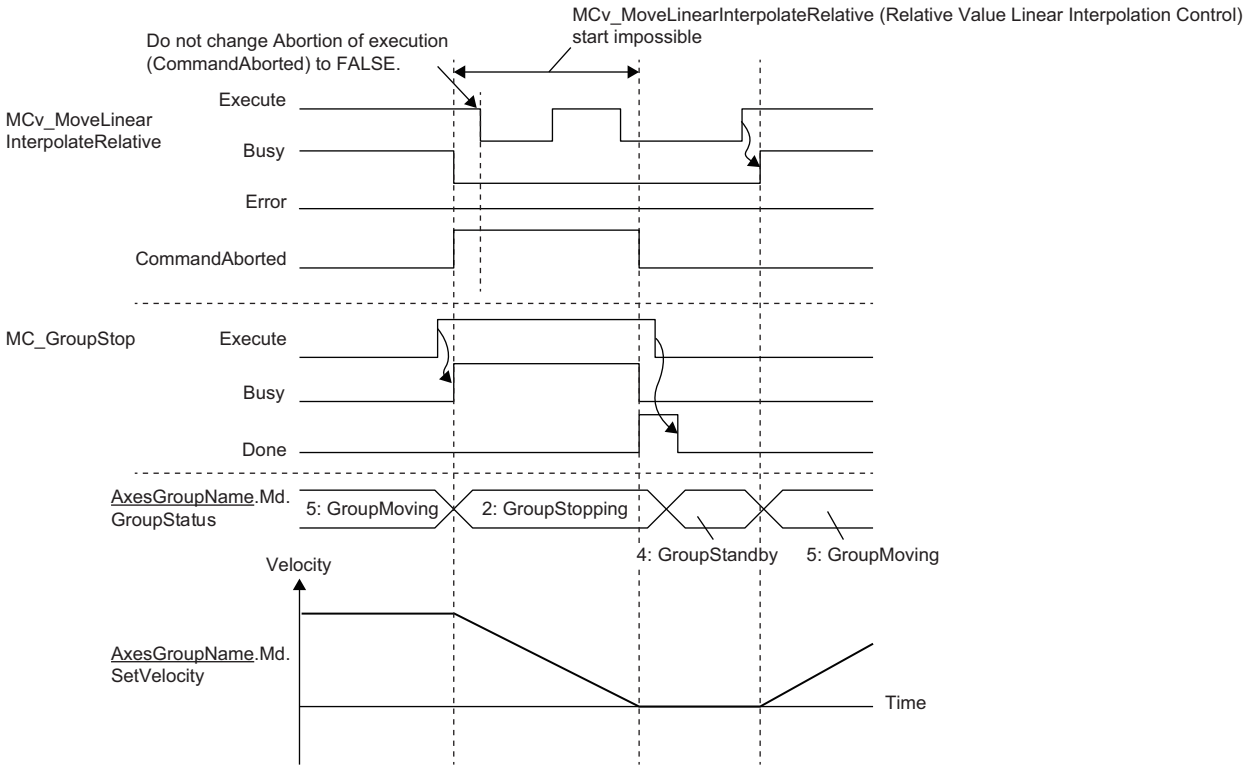
MC_GroupStop (Group Forced Stop)

In MC_GroupStop (Group Forced Stop), Deceleration (Deceleration) is set and the under-control FB is decelerated to stop. The axes group passes through the previous operation path and decelerates to a stop.



When MC_GroupStop (Group Forced Stop) is executed, Abortion of execution (CommandAborted) of the on-going FB becomes TRUE and Axes Group Status (AxesGroupName.Md.GroupStatus) transits to the "2: Decelerating to stop (GroupStopping)" status. While Execution command (Execute) is TRUE or while the speed does not reach 0, the "2: Decelerating to stop (GroupStopping)" status is maintained. When Execution completion (Done) becomes TRUE and Execution command (Execute) becomes FALSE at stop completion, the axes group status changes to the "4: Standby (GroupStandby)" status.

■MC_GroupStop (Group Forced Stop) execution during MCv_MoveLinearInterpolateRelative (Relative Value Linear Interpolation Control)



■Operation description

- During deceleration stop by this FB and while Execution command (Execute) of the input variable is TRUE, any operation command other than MC_GroupStop (Group Forced Stop) is not accepted.
- If Deceleration (Deceleration) is set with 0 or omitted, immediate stop will be executed.
- The acceleration/deceleration method and the jerk take over the method specified in the on-going control and deceleration is performed.
- When the setting value of Deceleration (Deceleration) is changed and MC_GroupStop (Group Forced Stop) is restarted, deceleration stop is executed from the restart point based on Deceleration (Deceleration) set in MC_GroupStop (Group Forced Stop) and Jerk (Jerk) used in the under-control FB.

- When an FB that operates axes other than MC_GroupStop (Group Forced Stop) is executed while Axes Group Status (AxesGroupName.Md.GroupStatus) is the "2: Decelerating to stop (GroupStopping)" status, Start Not Possible (error code: 1AFCH) occurs and Error of MC_GroupStop (Group Forced Stop) becomes TRUE, and then Axes Group Status (AxesGroupName.Md.GroupStatus) changes to "1: Stopping on error (GroupErrorStop)".

- Even if Execution command (Execute) of command aborted FB is set to FALSE by MC_GroupStop (Group Forced Stop), once the stop operation is started, Abortion of execution (CommandAborted) will remain TRUE until it is completed. After it stops completely, Abortion of execution (CommandAborted) is changed to FALSE if Execution command (Execute) of command aborted FB is FALSE.

Precautions

Relevant add-ons

The following add-ons are required to use this function.

- Axis
- MotionEngine
- ExternalSignal*1
- MotionControl_General*2
- ServoDriver_CANopen*3

*1 For using the stop signal, the forced stop signal, the all axes forced stop signal, and the upper/lower limit signal

*2 For using the following FBs

· MC_Stop (Forced Stop)

· MC_GroupStop (Group Forced Stop)

*3 For using the real drive axis or the real encoder axis

System memory usage

■Backup RAM usage

Backup RAM is not used.

26.5 Forced Stop

This function stops axes by the forced stop signal.

The axis types which the forced stop is valid are as follows

- The forced stop signal is valid for the following axis types which support Forced Stop Signal (AxisName.Pr.ForcedStop_Signal).
  - Real Drive Axis
  - Virtual Drive Axis
- All axes forced stop signal is effective for the following axis types, including the types which do not support Forced Stop Signal (AxisName.Pr.ForcedStop_Signal).
  - Real Drive Axis
  - Virtual Drive Axis
  - Virtual Linked Axis
- For details on the operation of the drive unit after the forced stop signal is sent, refer to each drive unit manual.

⚠WARNING

- When the forced stop is required to be wired, ensure to wire it in the negative logic, and normally closed contact is recommended.
- When using the forced stop function, check the wiring and the settings, and check whether the function works or not at startup.

Point

The forced stop function immediately stops the instruction. It issues "Quick Stop" to the device station whose axis assignment has been executed at the same time. For operation when "Quick Stop" is issued, refer to the manual of the device station.

Operation of this function for each system status

○: Available, ×: Not available

System status	Operation availability
STOP	○*1
RUN	○
Moderate error	○*2
Major error	○*2

*1 Forced Stop Signal (AxisName.Pr.ForcedStop_Signal) cannot be imported, so the operation cannot be performed if the status has never been set to RUN.

*2 "QuickStop" may not be issued depending on the error.
When a moderate or major error occurs, the motion system notifies the device station that an error has been detected in the CPU operating status.
For operation of the device station when an error is detected, refer to the manual for each device station.

Relevant variables

Axis parameter (AxisName.Pr.)

Variable/structure name	Name	Details
ForcedStop_Signal	Forced Stop Signal	Sets a signal using the each axis forced stop. Forced Stop Signal (ForcedStop_Signal) is the structure of SIGNAL_SELECT type. The fetch timing of the setting is at Ready ON, and the detection timing of the signal is the axis operation cycle. For details on SIGNAL_SELECT type, refer to the following. ☞ Page 1156 SIGNAL_SELECT Structure It may be regarded as signal detection, depending on the variable used as an external signal and the status of devices controlled by the controller. For details, refer to the following. ☞ Page 1154 EXTERNAL SIGNAL SELECTION The specific setting and the operation of this signal are shown below. ■I/O Number (StartIO) Ignores the input value. ■Target (Target) When the specification is not set, signal disabled is determined and the signal not detecting status is always set. Only [VAR], [DEV], and [CONST] can be specified for the data type. * If an unavailable value is set, Out of parameter range (axis) (error code: 1A60H) occurs. The error cause can be checked with the following detail codes. • An incorrect string was set (detail code: 0001H) • An unavailable data type was set (detail code: 0002H) • An unavailable type was specified (detail code: 0003H) • A type other than the numerical value type was specified at label specification (detail code: 0004H) • A signal that does not exist was set (detail code: 0005H) • A global label where access from an external device is disabled was set (detail code: 0005H) • The number of characters exceeded the upper limit (detail code: 0007H). • "Asynchronous" was set in the network synchronous communication setting of the device station being referred to (detail code: 8002H) • An unsupported device was set (detail code: 8002H) • A device number out of range was set (detail code: 8002H) ■Signal Detection Method (Detection) The specification is allowed at the following level detection only. • 0: Detection at TRUE (HighLevel) • 1: Detection at FALSE (LowLevel) * When edge detection specification is set, Out of parameter range (axis) (error code: 1A60H) (detail code: 8003H) occurs. ■Compensation Time (CompensationTime) Ignores the input value. ■Filter Time (FilterTime) Setting range of the filter time is 0.0 to +5.0. * When a value outside the range is set, Out of Filter Time Setting Range of Each Axis Signal Warning (event code: 00D24H) occurs and the axis operates with 0.0 of the filter time.

Axes group parameter (AxesGroupName.Pr.)

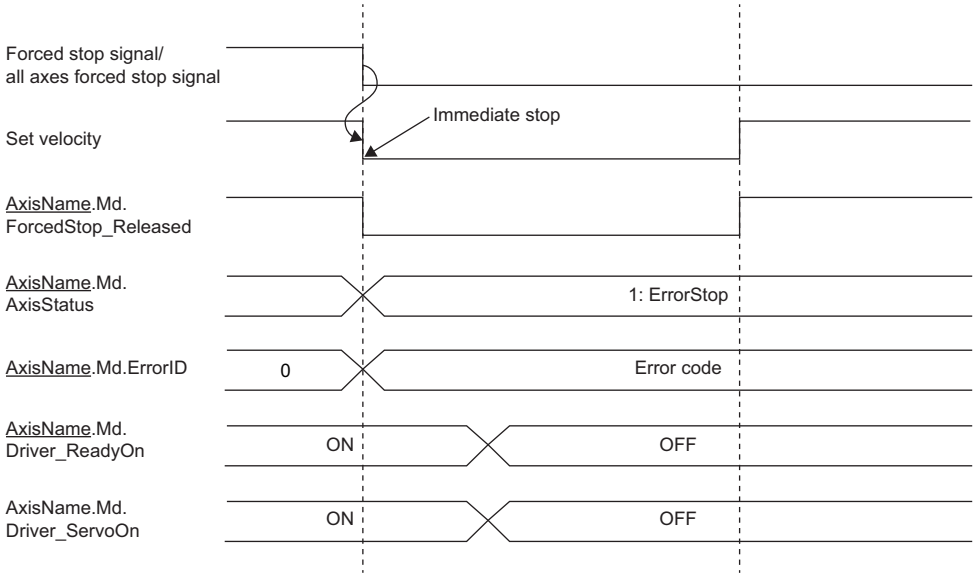
Variable/structure name	Name	Details
StopMode_ErrorInGroup	Configuration Axes Operation Selection at Axis Stop Cause Occurrence	During operation in the axes group, when the drive unit servo is turned off on the configuration axis and an immediate stop axis error occurs, it sets the operation of the axes on which the axis error has not occurred. 1: Immediate Stop (ImmediateStop) (Initial value)

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
ForcedStop_Released	Forced Stop Cancelling	Displays the forced stop cancel status. • FALSE: Forced stop input TRUE (Forced stop) • TRUE: Forced stop input FALSE (Forced stop release)
ForcedStop_Signal	Forced Stop Signal	Displays the input status of forced stop signal. Forced Stop Signal (ForcedStop_Signal) is the structure of SIGNAL_SELECT type. For details on SIGNAL_SELECT type, refer to the following. ☞ Page 1156 SIGNAL_SELECT Structure The specific output of this signal is shown below. ■I/O Number (StartIO) "0" is always displayed. ■Target (Target) The fetch result of the parameter is displayed. ■Signal Detection Method (Detection) The fetch result of the parameter is displayed. ■Compensation Time (CompensationTime) "0.0" is always displayed. ■Filter Time (FilterTime) The fetch result of the parameter is displayed.

System parameter (MotionSystem.Pr.)

Variable/structure name	Name	Details
ForcedStop_Signal	All Axes Forced Stop Signal	Sets a signal using the all axes forced stop. All Axes Forced Stop Signal (ForcedStop_Signal) is the structure of SIGNAL_SELECT type. The fetch timing of the setting is at Ready ON, the detection timing of the signal is the first operation cycle, and the timing to start the stop processing is the axis operation cycle. For details on SIGNAL_SELECT type, refer to the following. ☞ Page 1156 SIGNAL_SELECT Structure For precautions when multiple operation cycles coexist, refer to the following. ☞ Page 535 Operation Cycle Coexistence It may be regarded as signal detection, depending on the variable used as an external signal and the status of devices controlled by the controller. For details, refer to the following. ☞ Page 1154 EXTERNAL SIGNAL SELECTION The specific setting and the operation of this signal are shown below. ■I/O Number (StartIO) Ignores the input value. ■Target (Target) When the specification is not set, signal disabled is determined and the signal not detecting status is always set. Only [VAR], [DEV], and [CONST] can be specified for the data type. * When an unavailable data type is set, Out of parameter range (system) (error code: 1A62H) occurs. Out of parameter range (system) (error code: 1A62H) occurs if "Asynchronous" is set for the network synchronous communication setting of the device station being referred to when [VAR] or [DEV] is specified. ■Signal Detection Method (Detection) The specification is allowed at the following level detection only. When edge detection specification is set, Out of parameter range (system) (error code: 1A62H) is output. 0: Detection at TRUE (HighLevel) 1: Detection at FALSE (LowLevel) ■Compensation Time (CompensationTime) Ignores the input value. ■Filter Time (FilterTime) Setting range of the filter time is 0.0 to +5.0. * When a value outside the range is set, Out of Filter Time Setting Range of System Signal Warning (event code: 00F0FH) occurs and the axis operates with 0.0 of the filter time.



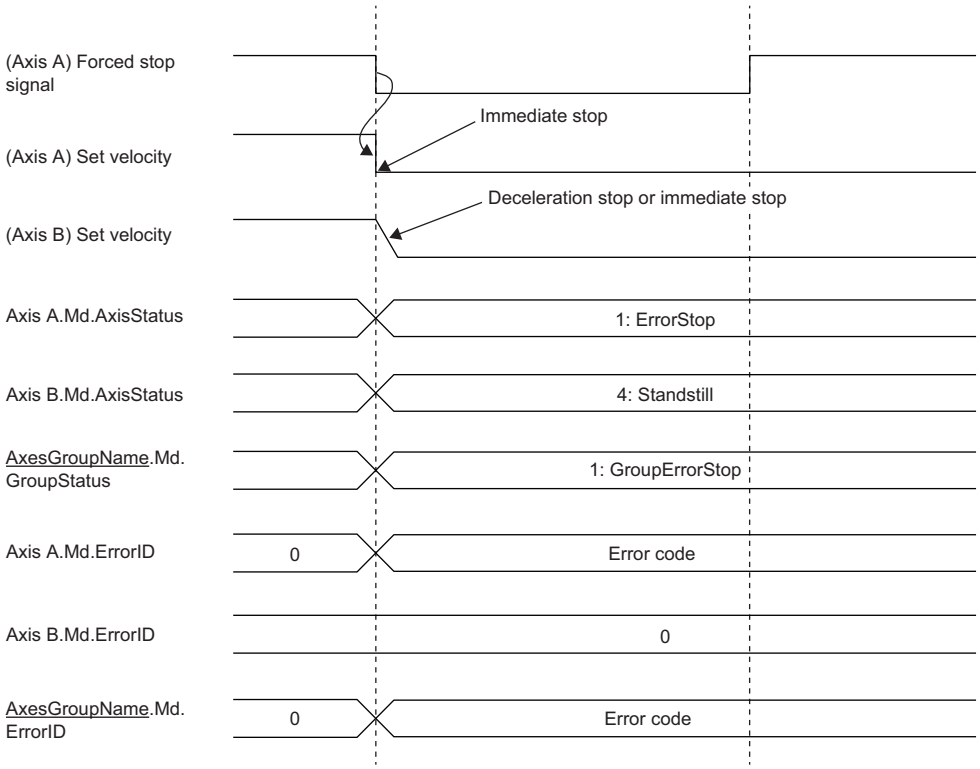
System Monitor Data (MotionSystem.Md.)

Variable/structure name	Name	Details
ForcedStop_Released	Forced Stop Cancelling	Displays the forced stop cancel status. • FALSE: All axes forced stop input TRUE (Forced stop) • TRUE: All axes forced stop input FALSE (Forced stop release)
ForcedStop_Signal	All Axes Forced Stop Signal	Displays the input status of all axes forced stop signal. All Axes Forced Stop Signal (ForcedStop_Signal) is the structure of SIGNAL_SELECT type. For details on SIGNAL_SELECT type, refer to the following. ☞ Page 1156 SIGNAL_SELECT Structure The specific output of this signal is shown below. ■I/O Number (StartIO) "0" is always displayed. ■Target (Target) The fetch result of the parameter is displayed. ■Signal Detection Method (Detection) The fetch result of the parameter is displayed. ■Compensation Time (CompensationTime) "0.0" is always displayed. ■Filter Time (FilterTime) The fetch result of the parameter is displayed.

Operation at the forced stop occurrence

This section describes the operation when a forced stop has occurred.
An example of a device station on which servo OFF is executed when "Quick Stop" is issued is connected as shown below.

During axis operation



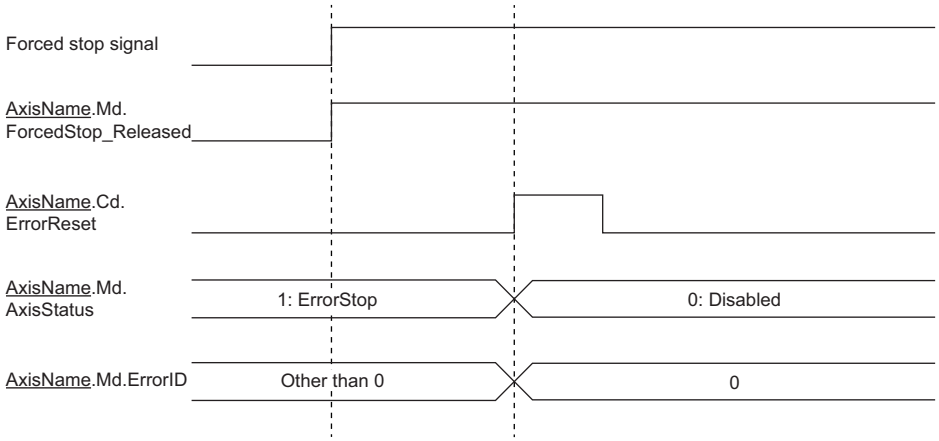
- In the axis on which a forced stop occurred, servo OFF is executed. The servo ON will not be executed until the forced stop is released. The error is not output when the axis is not operated.
- Regardless of whether during positioning or stop, "Forced stop detection" is registered in the event history. Forced stop status (error code: 1AC4H) is also registered in positioning.
- When the axis is in the forced stop status at start, the command will not be issued, and it will be in the same "1: Stopping on error (ErrorStop)" status as the forced stop that is in operation.

During stop

When the axis the forced stop occurred in is during stop, Forced stop status (error code: 1AC4H) will not occur. Axis Status (AxisName.Md.AxisStatus) transits according to the drive unit operation that received the forced stop signal of the controller.

During axes group operation

The following shows the operation when a forced stop has occurred to the axis A while an axes group configured with the axis A and B is being operated.



The stop method of the axis B can be set in Configuration Axes Operation Selection at Axis Stop Cause Occurrence (AxesGroupName.Pr.StopMode_ErrorInGroup). For the operation of each setting, refer to the following.

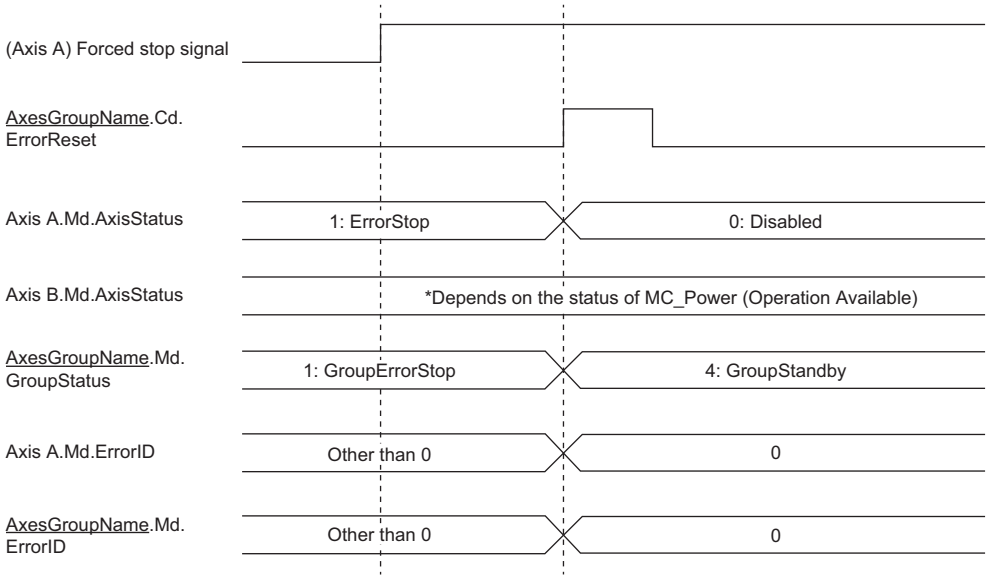
☞ Page 600 Stop cause occurrence in the configuration axis

Operation at the forced stop release

The operation the forced stop is released from the forced stop occurrence status is shown below.

Single axis

1. Release the forced stop.



- The forced stop input changes to "1".
- Axis Status (AxisName.Md.AxisStatus) is still "1: Stopping on error (ErrorStop)".

2. Execute the axis error reset.

- Axis Status (AxisName.Md.AxisStatus) changes to "0: Axis disabled (Disabled)".

Axes group

The following shows the release operation when a forced stop has occurred to the axis A while an axes group configured with the axis A and B is being operated.

1. Release the forced stop.

- The forced stop input changes to "1".
- Axes Group Status (AxesGroupName.Md.GroupStatus) is still "1: Stopping on error (GroupErrorStop)".

2. Execute the axes group error reset.

- Axes Group Status (AxesGroupName.Md.GroupStatus) changes to "4: Standby (GroupStandby)", and the error Nos. are cleared in both axis A and the axes group.

Point

When the forced stop is issued, the servo ON command of MC_Power (Operation Available) continues.

Check method

Whether the forced stop input is in the TRUE/FALSE status can be checked with Forced Stop Cancelling (AxisName.Md.ForcedStop_Released).

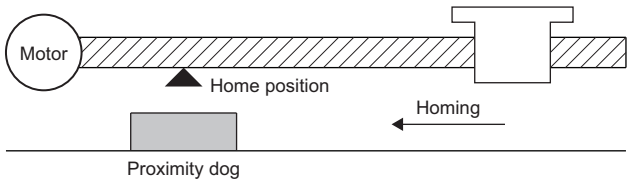
Precautions

Relevant add-ons

The following add-ons are required to use this function.

- Axis
- MotionEngine
- ExternalSignal

27 HOMING



In homing, a position is established as the starting (or "home position") when carrying out positioning control, and positioning is carried out toward that start point.
This control function is used to return a machine system at any position other than the home position to the home position when the motion system issues a homing request with the power turned on or others, or after a positioning stop.
The address information stored in the motion system cannot be guaranteed while the Homing Request (AxisName.Md.Homing_Request) is TRUE.
Homing Request (AxisName.Md.Homing_Request) is FALSE and Homing Completed (AxisName.Md.Homing_Complete) is TRUE if the homing is executed and is completed normally.

⚠WARNING

- When using an absolute position system, execute a homing always at the following cases: on starting up and when the controller or absolute position motor has been replaced. Check the homing request signal using the sequence program or others before performing the positioning control. Failure to observe this could lead to an accident such as a collision.

27.1 Overview

In homing, a machine home position is established.
None of the address information stored in the motion system or drive unit is used at this time.
The position mechanically established after the homing is regarded as the "home position" to be the start point for positioning control.

The following homing methods are available.

Item	Description	Reference
Driver homing method	Switches the drive unit to Homing mode, and executes homing based on the positioning pattern set on the drive unit side.	Page 620 Driver homing method
Data set homing method	Executes the homing to a virtual axis and a real axis that does not have the home position information in the device station side. It is completed in the motion system, and external signals or others are not used.	Page 623 Data set homing method

Homing method at homing starts is "driver homing method" when all of the following conditions are satisfied, or "data set homing method" when the following conditions are not satisfied.

- Axis type is real drive axis
- Drive unit supports Homing mode.
- "HomeOffset (607CH)" is set in object data.

Operation of this function for each system status

○: Available, ×: Not available

System status	Operation availability
STOP	×
RUN	○
Moderate error	×
Major error	×

Relevant variables

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
Homing_Status	Homing Operation Status	Stores the homing status of the drive unit.*1
Homing_Request	Homing Request	Becomes TRUE when homing is required and becomes FALSE when it is completed. For details, refer to the following. ☞ Page 619 Homing request
Homing_Complete	Homing Completed	Becomes TRUE when homing is normally completed, and it becomes FALSE when operation starts and homing is required.

*1 The following value of homing operation status is stored.

Stored value	Status	Statusword		
		Bit 13	Bit 12	Bit 10
FFFFH	Homing procedure is not in progress	—		
0000H	Homing procedure is in progress	0	0	0
0001H	Homing procedure is interrupted or not started	0	0	1
0002H	Homing is attained, but target is not reached	0	1	0
0003H	Homing procedure is completed successfully	0	1	1
0004H	Homing error occurred, velocity is not 0	1	0	0
0005H	Homing error occurred, velocity is 0	1	0	1

Relevant FB

For details on motion control FBs, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

Motion control FB	Name	Description
MC_Home	OPR	Executes homing of the specified axis.

Homing request

Homing request indicates that homing must be executed when Homing Request (AxisName.Md.Homing_Request) becomes TRUE.

Point

The reason why Homing Request (AxisName.Md.Homing_Request) became TRUE is recorded in event history.

For causes of which Homing Request (AxisName.Md.Homing_Request) becomes TRUE, refer to the following.

☞ Page 514 Homing request

Homing Request (AxisName.Md.Homing_Request) becomes FALSE at homing completion.

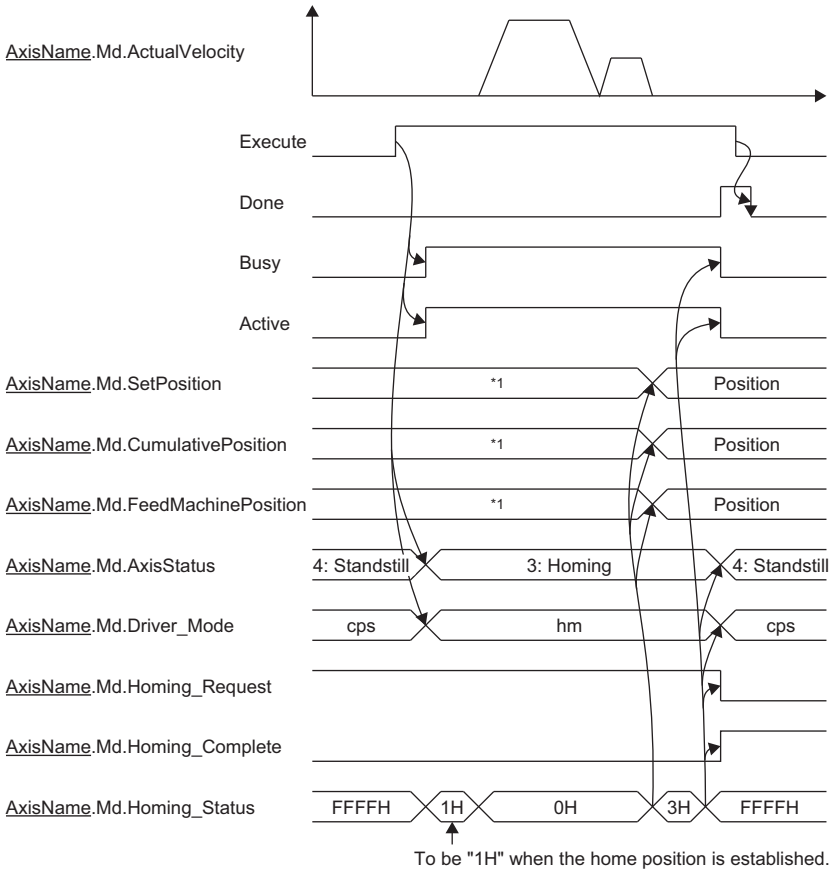
When homing is not required

Execute a homing request clear in systems that do not require homing. Homing Request (AxisName.Md.Homing_Request) becomes FALSE by performing Homing Request Clear. For details, refer to the following.

☞ Page 625 Operation Setting for Incompletion of Homing

Precautions

Directly rewriting Homing Request (AxisName.Md.Homing_Request) to FALSE with a program or others will not clear the homing request in the motion system. Be sure to use Homing Request Clear to set Homing Request (AxisName.Md.Homing_Request) to FALSE.



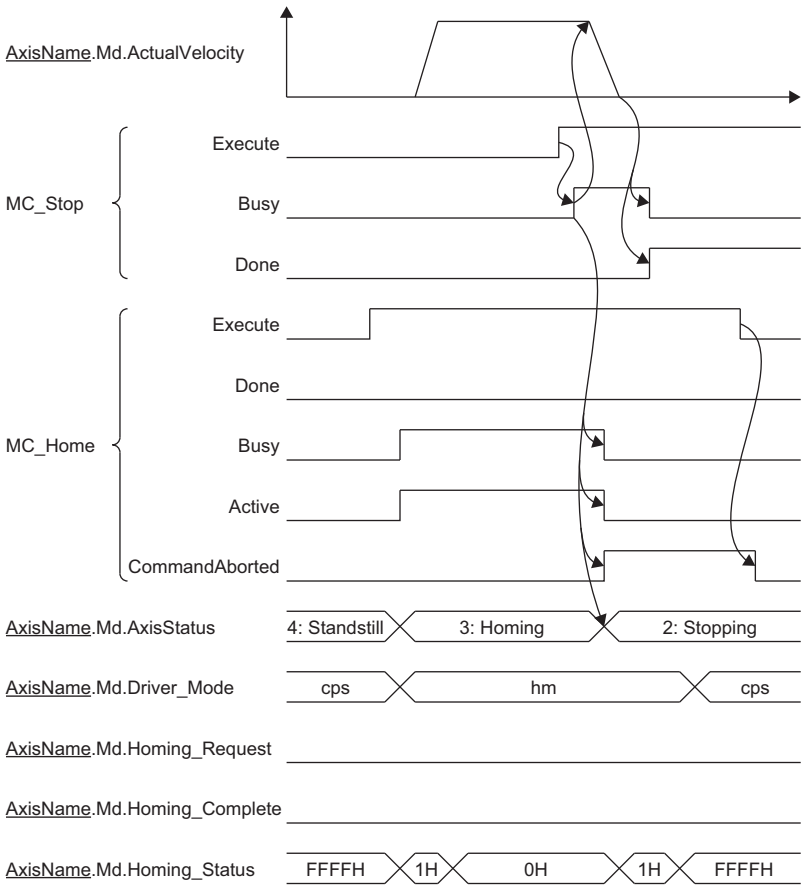
Driver homing method

The drive unit is switched to Homing mode, and homing is executed based on the positioning pattern set on the drive unit side. Change the homing data of the drive unit with MC_WriteParameter (Parameter Write) to change the homing method or each parameter.

Refer to the manual for the drive unit because the homing operation and settable parameters depend on the specifications of the drive unit.

Timing chart

■Normal operation



*1 When Follow-up enabled/disabled selection (Options (Options): bit 16) is set to "0: Follow-up disabled", it will not update during homing. When set to "1: Follow-up enabled", it will update with the current position changes during homing.

■When an error occurs

For details when an error occurs, refer to "Basic operation of Execution command (Execute) type Motion control FBs" in the following.

MELSEC MX Controller MX-R Model Programming Manual

■When MC_Stop (Forced Stop) is executed

- When MC_Stop (Forced Stop) is set to TRUE at homing, the "HALT" signal is sent to the drive unit. When using a drive unit that does not support HALT, use the forced stop because it does not stop with this signal.
- Stop processing at homing depends on the specifications of the drive unit. Therefore, Deceleration (Deceleration) and Jerk (Jerk) of MC_Stop (Forced Stop) are ignored.

Relevant object data

If no object data is set or no object exists in the device station, there will be errors and restrictions in the following function. For details on the object data settings, refer to the following.

☞ Page 466 Axis Assignment

○: Recommended

Instruction/function	Required object data (SDO)	Object required or not	Operation with no object
Driver homing method	Home offset	○	Operates with data set method. For details, refer to the following. ☞ Page 623 Data set homing method

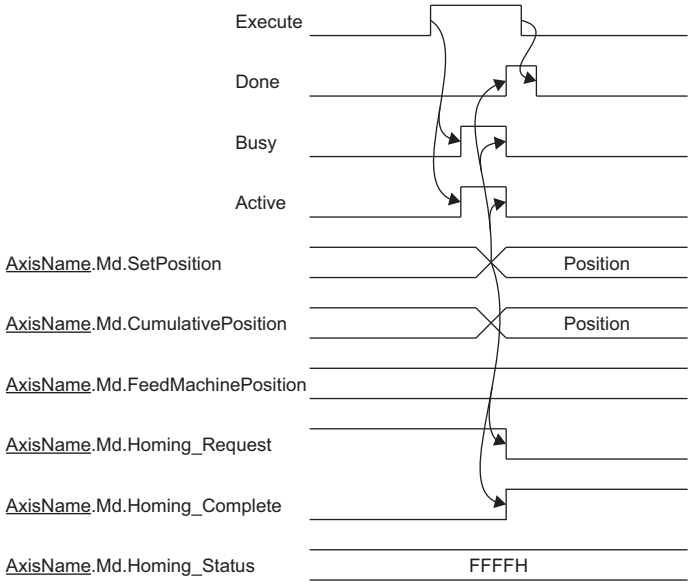
Precautions

- The homing cannot be started during servo-off. Thus, the drive unit homing method, Homing method 35 and 37 (Data set method), cannot be executed during servo OFF.
- When the external signals (the hardware stroke limit specified with axis variables and the proximity dog specified with Home position switch (AbsSwitch)) are assigned to the motion system, the external signals are transmitted to the drive unit. However, when the position accuracy is required in the proximity dog signal based (not Z-phase based) method, using the drive unit built-in DI is recommended.
- Immediately before homing is completed, monitor data such as feedback position (AxisName.Md.ActualPosition) may change rapidly regardless of the actual motor operation. Even if this phenomenon occurs, the monitor data after homing is not affected.
- When "0: Follow-up disabled" is selected in Follow-up enabled/disabled selection (Options (Options): bit 16), the follow up of set position is not performed during driver homing method. In this case, do not perform synchronous control with the axis during homing set as the master axis. Doing this may cause a Velocity range over during controlling (error code: 1B1AH) to occur in the slave axis.
- When "1: Follow-up enabled" is selected in Follow-up enabled/disabled selection (Options (Options): bit 16) and synchronous control is performed with the axis during homing set as the master axis, the slave axis operation is as follows depending on Master axis data source selection (MasterValueSource).

Master axis data source selection (MasterValueSource)	Slave axis operation during synchronous control
1: Set Value (mcSetValue) 101: Latest Set Value (mcLatestSetValue)	Continues synchronous control after homing completion.
2: Actual Value (mcActualValue) 102: Latest Actual Value (mcLatestActualValue)	Although the slave axis synchronizes to the master axis until homing is completed, the motor is suddenly accelerated or an excessive command is input without the synchronization control upon operation completion. This may cause an error or alarm on the drive unit side. For details, refer to the manuals for each drive unit. Example: For the MR-J5, the servo alarm [AL. 031.1_Servo motor speed error] or the servo alarm [AL. 035.1_Command frequency error] may occur.

- If the stop cause occurs when Homing Operation Status (AxisName.Md.Homing_Status) is set to "0002H: Homing completed (target is not reached to the target position)", the followed-up set position changes significantly. Therefore, an error, the servo alarm [AL. 031.1_Servo motor speed error], or the servo alarm [AL. 035.1_Command frequency error] may occur on the drive unit side even if "1: Set Value (mcSetValue)" or "101: Latest Set Value (mcLatestSetValue)" is selected in Master axis data source selection (MasterValueSource).
  For details, refer to the manuals for each drive unit.
- If the following items are not mapped, backup is not guaranteed.
  - Home cycle counter (2D3DH)
  - Home ABS counter (2D3EH)
- DOG signal inputted in the servo amplifier at MR-J5(W)-G connection can be specified as a home position switch signal. For details on the setting method, refer to the following.

☞ Page 2155 How to use



- The hardware stroke limit signal detection is performed during homing in the controller. When the signal is detected, the "HALT" signal is sent to the drive unit. To perform homing by using the hardware stroke limit signal, make the hardware stroke limit check of the controller side invalid temporarily by turning Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit_Override) to DISABLE (Check disabled).
- If ONLY_INSIDE (Check disabled for movement returning to the range) is set in Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit_Override) at homing start, Start not possible (error code: 1AFCH) occurs and the homing start is not carried out.
- When homing is performed with a drive unit other than the MELSERVO, set the parameters of the drive unit so that Home offset is 0. If a value other than 0 is set, an unintended operation may occur when the homing is completed.

Data set homing method

The data set homing method executes the homing to a virtual axis and a real axis that does not have the home position information in the device station side. It is completed in the motion system, and external signals or others are not used. Target position (Position) (home position address) at homing is registered in the motion system as the home position, and Set Position (AxisName.Md.SetPosition) and Cumulative Current Position (AxisName.Md.CumulativePosition) are rewritten to Target position (Position) (home position address).

Timing chart

■Normal operation

■When an error occurs

For details when an error occurs, refer to "Basic operation of Execution command (Execute) type Motion control FBs" in the following.

MELSEC MX Controller MX-R Model Programming Manual

Precautions

- FBs other than MC_Stop (Forced Stop) cannot start during homing.
- The software stroke limit check for Target position (Position) (home position address) at homing start is shown below.

Home position return method	Description
Driver homing method	The software stroke limit check is not performed.
Data set homing method	The software stroke limit check is performed.

- The software stroke limit check of the start position is not performed at homing start.
- The software stroke limit is not checked during homing.
- The movement direction at homing completion is in positive direction.
- Homing does not support the velocity bias function. Set the minimum motor speed of the driver homing method by the drive unit.

Error

Check that Axis Status (AxisName.Md.AxisStatus) is "4: Standby (Standstill)" at MC_Home (Homing) execution. If the status is other than "4: Standby (Standstill)", an error will occur and the control during operation will stop.

Relevant add-ons

The following add-ons are required to use this function.

- Axis
- MotionEngine
- MotionControl_General
- NetworkDriver_CCIETSN (When using the real axis)
- ServoDriver_CANopen (When using the real axis)
- SignalIO (When using AbsSwitch)

27.2 Operation Setting for Incompletion of Homing

The operation setting for incompletion of homing is provided to select whether the axis is started or not when Homing Request (AxisName.Md.Homing_Request) is TRUE.

When starting the axis at homing incompletion, whether the axis can start up or not is determined by the executed FB and Start Permission at Homing Uncompleted (AxisName.Pr.StartableAtUnhomed).

○: Axis start possible, ×: Axis start impossible

FB	Start Permission at Homing Uncompleted (AxisName.Pr.StartableAtUnhomed)	
	"TRUE: Allow" and the homing request (AxisName.Md.Homing_Request) is TRUE.	"FALSE: Not allowed" and the homing request (AxisName.Md.Homing_Request) is TRUE.
FBs that can be started if homing is incompletion	○*1	○*1
The motion FBs other than the above	○*1	×

*1 There may be restrictions in the operation for incompletion of homing depending on the setting or specifications of the drive unit. For details, refer to each drive unit manual.
For MR-J5(W)-G: MR-J5 User's Manual (Function)

Relevant variables

Axis parameter (AxisName.Pr.)

Variable/structure name	Name	Details
StartableAtUnhomed	Start Permission at Homing Uncompleted	Sets whether axis start is allowed or not when homing is incomplete. • FALSE: Not allowed • TRUE: Allowed

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
Homing_Request	Homing Request	Becomes TRUE when homing is required and becomes FALSE when it is completed. For details, refer to the following. ☞ Page 619 Homing request

Axis control data (AxisName.Cd.)

Variable/structure name	Name	Details
Homing_ClearRequest	Homing Request Clear	Sets the homing request to FALSE forcibly. After the homing request is set to FALSE, FALSE is set in this variable automatically. • FALSE: Not execute • TRUE: Executes Homing Request Clear

FBs that can be started when homing is incomplete

The following FBs can start the axis regardless of Start Permission at Homing Uncompleted (AxisName.Pr.StartableAtUnhomed) and Homing Request (AxisName.Md.Homing_Request) status.

FBs that can be started when homing is incomplete
MC_Home (Homing)
MCv_Jog (JOG operation)
MC_Stop (Forced stop)
MC_GroupStop (Group forced stop)
FBs other than the motion FBs

The axis start other than the above cannot start the axis when Start Permission at Homing Uncompleted (AxisName.Pr.StartableAtUnhomed) is FALSE and Homing Request (AxisName.Md.Homing_Request) is TRUE, and Start at homing incompletion (error code: 1A99H) occurs.

Homing request clear

When Homing Request (AxisName.Md.Homing_Request) is TRUE, Homing Request (AxisName.Md.Homing_Request) can be changed to FALSE forcibly by setting Homing Request Clear (AxisName.Cd.Homing_ClearRequest) to TRUE.

Precautions

- In Homing Request Clear (AxisName.Cd.Homing_ClearRequest), when turning Homing Request (AxisName.Md.Homing_Request) to FALSE and starting the axis, it is operated not based on the home position but based on the current coordinate system.
- Do not turn Homing Request Clear (AxisName.Cd.Homing_ClearRequest) to TRUE during homing.

28 AXIS CONTROL FUNCTIONS

The axis control function has the following items.

Item	Description	Reference
Single axis positioning control	Executes positioning to the specified position by using address information.	Page 627 Single Axis Positioning Control
Single axis speed control	Executes the speed control for the specified axis with the specified speed.	Page 629 Single Axis Speed Control
Single axis manual control	Executes any positioning operation by inputting a signal from the outside.	Page 631 Single Axis Manual Control
Multiple axes positioning control	Uses address information and executes positioning to the specified position using interpolation control.	Page 636 Multiple Axes Positioning Control
Multiple axes positioning data operation	Executes positioning for the axes group with the specified positioning method and speed to the preset passing point in one start.	Page 665 Multiple Axes Positioning Data Operation

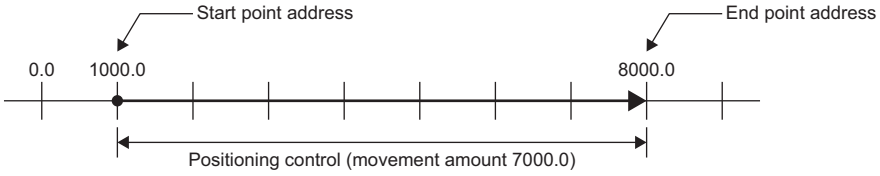
28.1 Single Axis Positioning Control

This function executes positioning to the specified position by using address information.

Relevant FBs

For details on motion control FBs, refer to the following.

📖MELSEC MX Controller MX-R Model Programming Manual



Motion control FB	Name	Description
MC_MoveAbsolute	Absolute value positioning	Executes positioning after specifying the target position of the absolute position.
MC_MoveRelative	Relative value positioning	Executes positioning after specifying the movement amount of the relative position.

Absolute value positioning control

In MC_MoveAbsolute (Absolute Value Positioning), Target position (Position), Velocity (Velocity), Acceleration (Acceleration), Deceleration (Deceleration), Jerk (Jerk), Direction selection (Direction), Buffer mode (BufferMode), and Options (Options) can be set, and positioning is executed from the current position at start (start point address) to the address (end point address) set in Target position (Position).

Ex.

When the start point address is 1000.0, and Target position (Position) is 8000.0, positioning is carried out in the positive direction for a movement amount of 7000.0 (8000.0 - 1000.0).

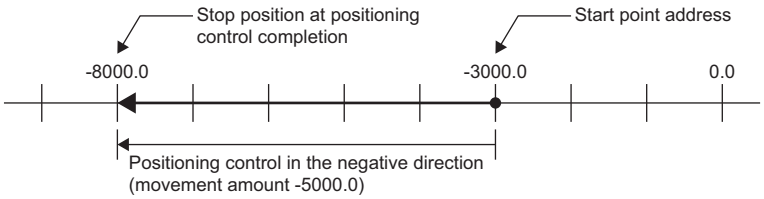
Required object data

When using MC_MoveAbsolute (Absolute Value Positioning), map the object assigned to the following object data to PDO.

- Target position (607AH)

If the above object is not mapped to PDO, Required object data unset (error code: 1AF7H) will occur and the operation will not start.

For details on the object data settings, refer to the following.



☞ Page 466 Axis Assignment

Relative value positioning control

In MC_MoveRelative (Relative Value Positioning), Movement amount (Distance), Velocity (Velocity), Acceleration (Acceleration), Deceleration (Deceleration), Jerk (Jerk), and Buffer mode (BufferMode) can be set, and positioning of movement amount set in Movement amount (Distance) is executed from the current position at start (start point address). The movement direction is determined by the sign of the movement amount. Axis Status (AxisName.Md.AxisStatus) becomes "5: During positioning operation (DiscreteMotion)".

Ex.

When the start point address is -3000.0, and the movement amount is -5000.0, positioning is carried out to -8000.0.

Required object data

When using MC_MoveRelative (Relative Value Positioning), map the object assigned to the following object data to PDO.

- Target position (607AH)

If the above object is not mapped to PDO, Required object data unset (error code: 1AF7H) will occur and the operation will not start.

For details on the object data settings, refer to the following.

☞ Page 466 Axis Assignment

Precautions

- Even if a restart or continuous update is performed, the current position where this FB was started for the first time is the starting address.
- Since it is processed with the floating point type, if the relative value positioning control is repeatedly executed, the movement amount specified may not be reached due to the calculation error.

28.2 Single Axis Speed Control

This function executes the speed control for the specified axis with the specified speed.

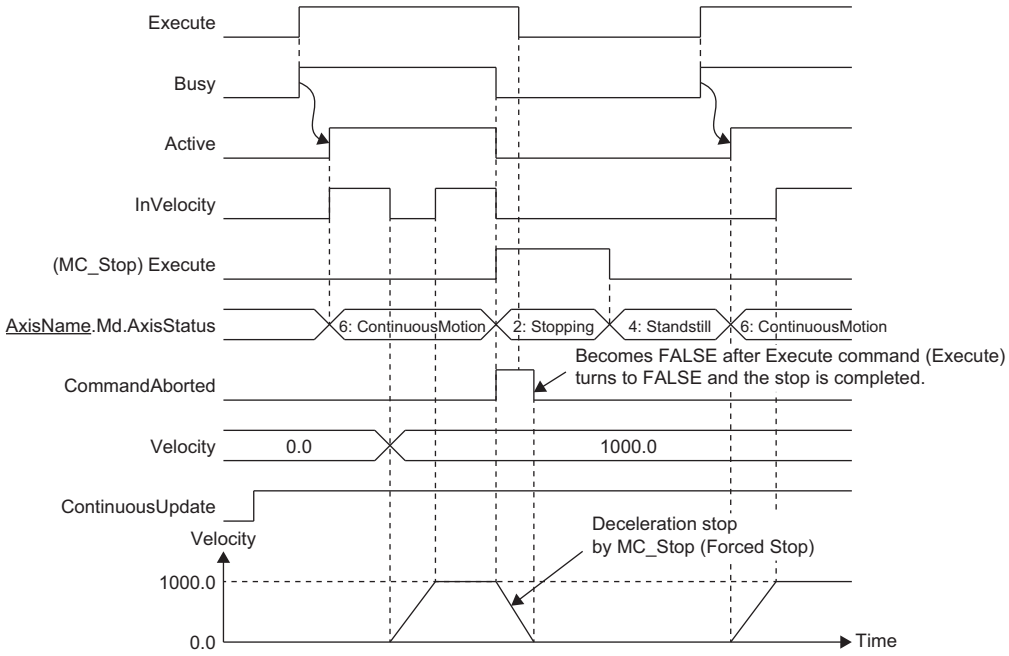
For speed control excluding position loop, refer to the following.

☞ Page 715 Velocity Control

Relevant FBs

For details on motion control FBs, refer to the following.

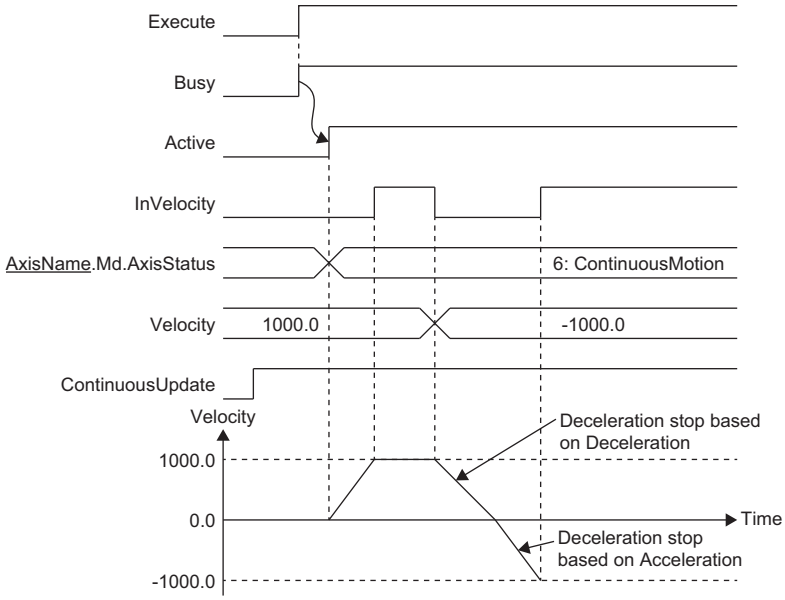
📖MELSEC MX Controller MX-R Model Programming Manual



Motion control FB	Name	Description
MCv_SpeedControl	Speed control (including position loop)	Executes the speed control including position loop.

Control details

Set the control mode of the drive unit side to cyclic synchronous position mode (csp) and perform speed control for the specified axis with the specified speed. MCv_SpeedControl (Speed Control (Including Position Loop)) is used to execute. To stop the axis, use MC_Stop (Forced Stop) or start another motion FB.



To perform speed control with the control mode of the drive unit side set to the cyclic synchronous velocity mode (csv), use an FB such as MC_MoveVelocity (Speed Control).

Timing chart at start and the stop cause occurrence

Timing chart when the operation direction is changed

If the sign of Velocity (Velocity) is reversed and the operation direction is changed when Continuous update (ContinuousUpdate) is TRUE, the axis accelerates toward the target velocity once after the deceleration stop.

BufferMode

Select a buffer mode. Aborting, Buffered, BlendingLow, BlendingPrevious, BlendingNext, and BlendingHigh can be set.
For details on the operation, refer to the following.
☞ Page 548 Buffer mode type

Required object data

When using Speed Control (Including Position Loop) for a single axis, map the object assigned to the following object data to PDO.

- Target position (607AH)

If the above object data is not mapped to PDO, Required object data unset (error code: 1AF7H) will occur and the operation will not start.
For details on the object data settings, refer to the following.
☞ Page 466 Axis Assignment

28.3 Single Axis Manual Control

This function executes any positioning operation by inputting a signal from the outside.

Relevant variables

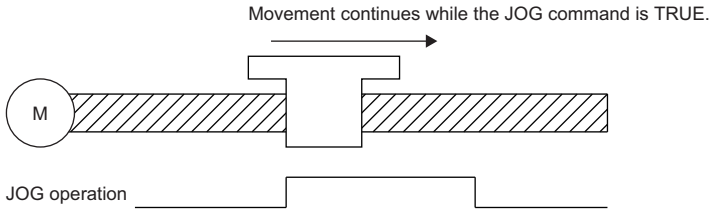
Axis control data (AxisName.Cd.)

Variable/structure name	Name	Details
SwStrokeLimit_Override	Software Stroke Limit Override	Temporarily switches valid/invalid of the software stroke limit check. • DISABLE: Check disabled • ONLY_INSIDE: Check disabled only for movement returning to the range • Other than the above: Check enabled (no disabling request)
HwStrokeLimit_Override	Hardware Stroke Limit Override	Temporarily switches valid/invalid of the hardware stroke limit check. • DISABLE: Check disabled • ONLY_INSIDE: Check disabled only for movement returning to the range • Other than the above: Check enabled (no disabling request)

Relevant FB

For details on motion control FBs, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual



Motion control FB	Name	Description
MCv_Jog	JOG operation	Executes JOG operation according to the command velocity.

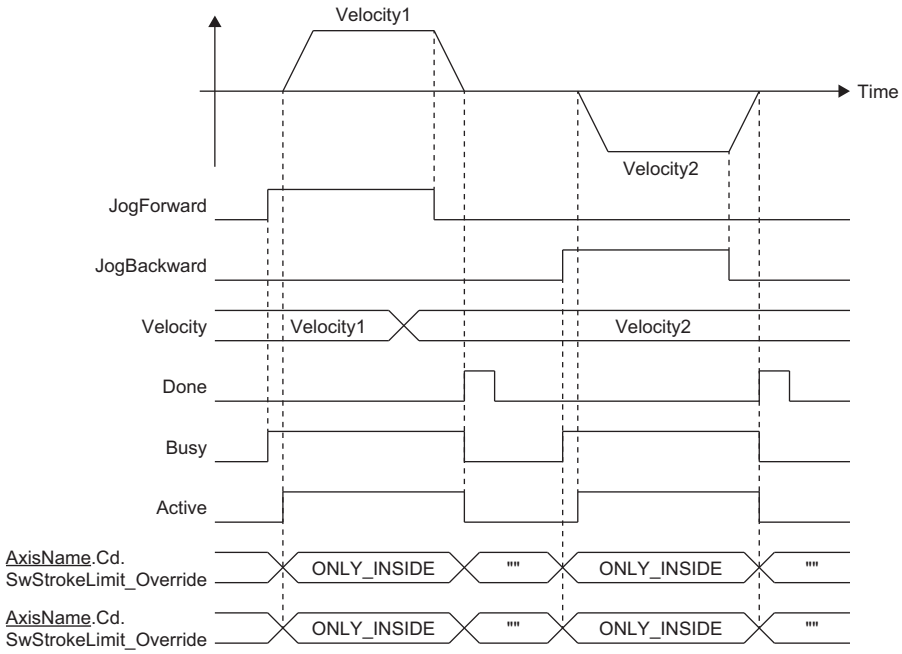
Types of manual control

There is the following type of manual control.

JOG operation

JOG operation is a control method in which the machine is moved by only a movement amount (commands are continuously output while the JOG command is TRUE).

JOG operation



In JOG operation, the command is output from the motion system to the axis while the positive/reverse rotation JOG command is input by using MCv_Jog (JOG Operation), and then the axis operates in the specified direction.

Point

- JOG operation can be executed even when the homing is not completed.
- JOG operation can be started from outside to inside of the software stroke limit range. (If the JOG operation is started in the outside direction of the software stroke limit range, an error will occur.)
- JOG operation can be started from outside to inside of the hardware stroke limit range. (If the JOG operation is started in the outside direction of the hardware stroke limit range, an error will occur.)

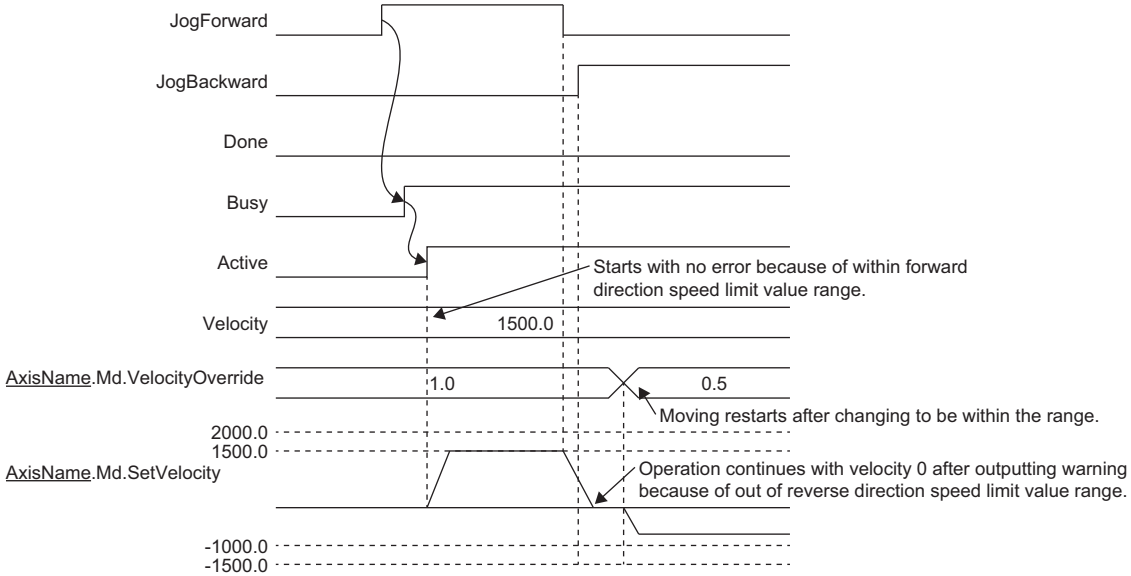
Ex.

When a reverse rotation JOG operation is executed after a positive rotation JOG operation

Control details

- JOG operation is carried out with MCv_Jog (JOG Operation).
- The target axis is moved in the specified direction during TRUE, by setting Positive rotation JOG command (JogForward) or Reverse rotation JOG command (JogBackward) to TRUE.
- Axis Status (AxisName.Md.AxisStatus) during JOG operation is "6: During continuous operation (ContinuousMotion)".
- A deceleration stop is executed by setting Positive rotation JOG command (JogForward) or Reverse rotation JOG command (JogBackward) to FALSE. Axis Status (AxisName.Md.AxisStatus) changes to "4: Standby (Standstill)" after the deceleration stop is completed.
- When Error (Error) becomes TRUE during the deceleration by setting Positive rotation JOG command (JogForward) or Reverse rotation JOG command (JogBackward) to FALSE, Error (Error) becomes TRUE until Positive rotation JOG command (JogForward) or Reverse rotation JOG command (JogBackward) is changed TRUE.
- When another operation instruction is started during a JOG operation, the operation is carried out based on the Buffer mode (BufferMode) setting.
- When a JOG operation is started during another operation instruction, the start request will be ignored and Start during Operation Warning (event code: 00D01H) will occur. Start a JOG operation when Axis Status (AxisName.Md.AxisStatus) is "4: Standby (Standstill)".
- Use velocity change by the override function to change the velocity during JOG operation.

For details on the override function, refer to the following.



☞ Page 1116 Override Function

Precautions

- For safety, set a small value in Velocity (Velocity) first and check the movement, and then gradually increase the value.
- Use the hardware stroke limit function when carrying out JOG operation near the upper or lower limits. If the hardware stroke limit function is not used, the workpiece may exceed the moving range and cause an accident.
- When the software stroke limit function is valid and Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit_Override) is other than DISABLE (Check disabled) or ONLY_INSIDE (Check disabled for movement returning to the range), Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit_Override) is rewritten into ONLY_INSIDE (Check disabled for movement returning to the range) during MCv_Jog (JOG Operation) execution, and it is rewritten into "" when the JOG operation is completed.
- When the hardware stroke limit function is valid and Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit_Override) is other than DISABLE (Check disabled) or ONLY_INSIDE (Check disabled for movement returning to the range), Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit_Override) is rewritten into ONLY_INSIDE (Check disabled for movement returning to the range) during MCv_Jog (JOG Operation) execution, and it is rewritten into "" when the JOG operation is completed.
- Do not change Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit_Override) and Hardware Stroke Limit Override (AxisName.Cd. HwStrokeLimit_Override) during MCv_Jog (JOG Operation) execution.
- Note that the values of Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit_Override) and Hardware Stroke Limit Override (AxisName.Cd. HwStrokeLimit_Override) are retained to the next instruction during multiple start because the next instruction is analyzed during operation when multiple start is executed during JOG operation.
- When moving in the reverse direction against the direction at start after deceleration stop during JOG operation, if the target velocity exceeds the velocity limit value, Velocity Limit Value Over Warning on Direction Change (event code: 00D20H) occurs. In addition, when the acceleration time exceeds 8400.0 [s], Acceleration Time Over Warning on Direction Change (event code: 00D32H) occurs. (The operation continues with velocity 0.) The movement starts after changing control to remove the cause.

Ex.

When setting Positive Direction Velocity Limit Value (AxisName.Pr.VelocityLimit_Positive) to "2000.0", and Negative Direction Velocity Limit Value (AxisName.Pr.VelocityLimit_Negative) to "1000.0"

Required object data

When using JOG operation, map the object assigned to the following object data to PDO.

- Target position (607AH)

If the above object is not mapped to PDO, Required object data unset (error code: 1AF7H) will occur and the operation will not start.

For details on the object data settings, refer to the following.

☞ Page 466 Axis Assignment

28.4 Multiple Axes Positioning Control

This function uses address information and executes positioning to the specified position using interpolation control.

Relevant variables

Axes group information (AxesGroupName.AxesGroupRef.)

Variable/structure name	Name	Details
GroupNo	Axes Group No.	Indicates axes group No. • 0: Not set • 1 to 10000: Set axes group No.

Axes group parameter (AxesGroupName.Pr.)

Variable/structure name	Name	Details
Axis[1..16]	Configuration Axis	Sets Axis No. (AxisNo) of Axis Information (AxisName.AxisRef) which configures the axes group.
VelocityLimit	Velocity Limit Value	Sets the velocity limit value.

Axes group monitor data (AxesGroupName.Md.)

Variable/structure name	Name	Details
NumberOfAxes	Number of Configuration Axes	Displays the number of configuration axes of the axes group.
InterpolationAxes	Interpolation Axes	Displays the configuration axis that is executing the interpolation control of the axes group in bits.
SetVelocity	Set Velocity	Displays the set output velocity of the axes group.

Monitor data in multiple axes positioning control

Configuration axes of the axes group that are used for the multiple axes positioning control can be checked in Interpolation Axes (AxesGroupName.Md.InterpolationAxes).

Relevant FB

For details on motion control FBs, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

Motion control FB	Name	Description
MCv_MoveLinearInterpolateAbsolute	Absolute value linear interpolation control	Specifies the target position of the absolute position of specified axes group, and executes positioning by linear interpolation control.
MCv_MoveLinearInterpolateRelative	Relative value linear interpolation control	Specifies the movement amount of the relative position of specified axes group, and executes positioning by linear interpolation control.
MCv_MoveCircularInterpolateAbsolute	Absolute value circular interpolation control	Executes positioning by 2-axis circular interpolation by using configuration axes of set axes group, and by specifying the end point and the sub point of the absolute position.
MCv_MoveCircularInterpolateRelative	Relative value circular interpolation control	Executes positioning by 2-axis circular interpolation by using configuration axes of set axes group, and by specifying the relative position from the current position at start to the end point and the sub point.

Multiple axes positioning control types

There are the following types of multiple axes positioning controls.

Classification of positioning control	Classification of multiple axes	Classification of interpolation	Classification of control
Multiple axes positioning control	Multiple axes interpolation control	Linear interpolation control	Absolute value linear interpolation control
			Relative value linear interpolation control
		Circular interpolation control	Absolute value circular interpolation control
			Relative value circular interpolation control

Operation in multiple axes positioning control

- In the multiple axes positioning control, the positioning control with multiple axes using an axes group can be executed.
- To execute the multiple axes positioning control, axes group settings and enabling are required. For details, refer to the following.

☞ Page 478 Axes Group
☞ Page 487 Axes Group Assignment

- In multiple axes positioning control, specify axes (interpolation axes) to be used for interpolation control in the configuration axis of the axes group. Up to 4 interpolation axes can be specified.

Positioning speed in multiple axes positioning control

Positioning speed at multiple axes positioning control can be set in Velocity (Velocity) of the motion control FB. In positioning control, a control target is controlled at the specified positioning speed.

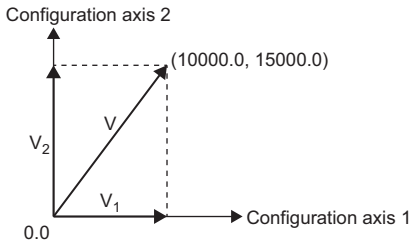
Linear interpolation control

To specify the positioning speed for the linear interpolation control, the following three methods can be used.

- Vector velocity specification
- Long axis velocity specification
- Reference axis velocity specification

The motion system control methods for each set method are described in the following.

■Vector velocity specification



The positioning speed of each interpolation axis is calculated from the movement amount of each interpolation axis by the motion system based on the positioning speed of the set control target.

The positioning speed of the control target is called the vector velocity.

Set each input in the motion control FB: Linear interpolation axes (LinearAxes) as the interpolation axes, Target position (Position) or Movement amount (Distance) as the movement amount of each interpolation axis, and Velocity (Velocity) as the vector velocity.

Ex.

For 2-axis linear interpolation control

Setting item	Setting value
Linear interpolation axes	Configuration axis 1, Configuration axis 2
Configuration axis 1 movement amount (D_1)	10000.0 [pulses]
Configuration axis 2 movement amount (D_2)	15000.0 [pulses]
Velocity unit of axes group	[s]
Vector velocity (V)	7000.0 [pulses/s]

For the above conditions, the positioning speed of each axis is calculated by the motion system with the following calculation formulas.

Setting item	Setting value
Configuration axis 1 positioning speed	$V_1 = V \times D_1 / \sqrt{(D_1^2 + D_2^2)}$
Configuration axis 2 positioning speed	$V_2 = V \times D_2 / \sqrt{(D_1^2 + D_2^2)}$

Point

For the vector velocity specification, the set velocity limit value is valid to the Velocity (Velocity) which is as the vector velocity. For details, refer to the following.

☞ Page 1112 Velocity Limit

■Long axis velocity specification

The control is carried out based on the positioning speed (the long axis velocity) of interpolation axes whose movement amount is the largest in the addresses set in each interpolation axis.

The positioning speed of the other interpolation axes is calculated by the motion system from the movement amount of each interpolation axis.

Set each input in the motion control FB: Linear interpolation axes (LinearAxes) as the interpolation axes, Target position (Position) or Movement amount (Distance) as the movement amount of each interpolation axis, and Velocity (Velocity) as the long axis velocity.

Ex.

For 4-axis linear interpolation control

Setting item	Setting value
Linear interpolation axes	Configuration axis 1, Configuration axis 2, Configuration axis 3, Configuration axis 4
Configuration axis 1 movement amount (D_1)	10000.0 [pulses]
Configuration axis 2 movement amount (D_2)	15000.0 [pulses]
Configuration axis 3 movement amount (D_3)	5000.0 [pulses]
Configuration axis 4 movement amount (D_4)	20000.0 [pulses]
Configuration axis 4 velocity unit	[s]
Long axis velocity (V)	7000.0 [pulses/s]

In the above case, the long axis is the configuration axis 4 whose movement amount is the largest, and the control is carried out by long axis velocity to the configuration axis 4. The positioning speed of the other interpolation axes is calculated by the motion system with the following calculation formulas.

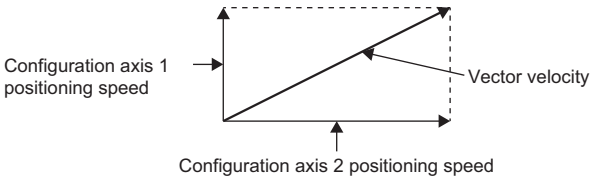
Setting item	Setting value
Configuration axis 1 positioning speed	$V_1 = D_1 / D_4 \times V$
Configuration axis 2 positioning speed	$V_2 = D_2 / D_4 \times V$
Configuration axis 3 positioning speed	$V_3 = D_3 / D_4 \times V$

Point

- For the long axis velocity specification, set velocity limit value is valid for the Velocity (Velocity) which is as the long axis velocity. For details, refer to the following.

☞ Page 1112 Velocity Limit

- Note that the vector velocity when specifying the long axis velocity may be larger than the velocity limit value. When setting a value like the following in the 2-axis linear interpolation, the vector velocity exceeds the velocity limit value.



(Example)

When the setting items and the setting values are as follows.

- Linear interpolation axes: Configuration axis 1, Configuration axis 2
- Configuration axis 1 movement amount: 100 [pulses]
- Configuration axis 2 movement amount: 200 [pulses]
- Long axis velocity: 50 [pulses/s]
- Velocity limit value of configuration axis 2: 55 [pulses/s]

In the above case, the reference axis is configuration axis 2 whose movement amount is the largest, and the control is carried out based on the velocity limit value specified in configuration axis 2. The positioning speed and the vector velocity of each axis are shown below.

- Configuration axis 1 positioning speed: 100/200 × 50 = 25 [pulses/s]
- Configuration axis 2 positioning speed: 50 [pulses/s]
- Vector velocity: $\sqrt{(25^2 + 50^2)} = 55.9$ [pulses/s]

The vector velocity becomes a value that exceeds the velocity limit value "55" of configuration axis 2.

■Reference axis velocity specification

The motion system controls the positioning speed of other interpolation axes calculating from each interpolation axis movement amount based on the positioning speed of the set reference axis (the reference axis velocity), and carries out the control.

In the motion control FB, set Linear interpolation axes (LinearAxes) as interpolation axes to ensure that the reference axis is the first element of the array in Linear interpolation axes (LinearAxes). Also, set Target position (Position) or Movement amount (Distance) as the movement amount of each axis and set the Velocity (Velocity) as the reference axis speed.

- If "0.0" is set to the movement amount of the configuration axis specified as the reference axis, Reference axis movement amount 0 (error code: 1AFAH) occurs.

Ex.

For 4-axis linear interpolation control

Setting item	Setting value
Linear interpolation axes	Configuration axis 1, Configuration axis 2, Configuration axis 3, Configuration axis 4
Configuration axis 1 movement amount (D_1)	10000.0 [pulses]
Configuration axis 2 movement amount (D_2)	15000.0 [pulses]
Configuration axis 3 movement amount (D_3)	5000.0 [pulses]
Configuration axis 4 movement amount (D_4)	20000.0 [pulses]
Configuration axis 4 velocity unit	[s]
Reference axis velocity (V)	7000.0 [pulses/s]

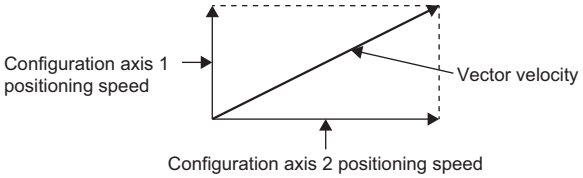
In the above case, the reference axis is configuration axis 4, and control is carried out at the positioning speed specified in configuration axis 4.
The positioning speed of the other interpolation axes is calculated by the motion system with the following calculation formulas.

Setting item	Setting value
Configuration axis 1 positioning speed	$V_1 = D_1 / D_4 \times V$
Configuration axis 2 positioning speed	$V_2 = D_2 / D_4 \times V$
Configuration axis 3 positioning speed	$V_3 = D_3 / D_4 \times V$

Point

- For the reference axis velocity specification, the set velocity limit value works on Velocity (Velocity) as the reference axis velocity. For details, refer to the following.

☞ Page 1112 Velocity Limit

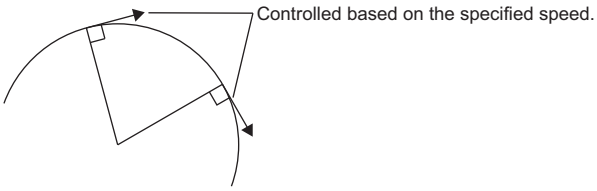


- Note that the positioning speed of the axis whose movement amount is larger than that of the reference axis is larger than the set reference axis velocity. When setting a value like the following in the 2-axis linear interpolation, the positioning speed and the vector velocity of the configuration axis 2 exceed the velocity limit value.

(Example)
When the setting items and the setting values are as follows.

- Linear interpolation axes: Configuration axis 1, Configuration axis 2
- Configuration axis 1 movement amount: 100 [pulses]
- Configuration axis 2 movement amount: 200 [pulses]
- Reference axis velocity: 50 [pulses/s]
- Velocity limit value of configuration axis 1: 55 [pulses/s]

In the above case, the reference axis is configuration axis 1, and control is carried out with the velocity limit value which is set in configuration axis 1. The positioning speed and the vector velocity of each configuration axis are shown below.



- Configuration axis 1 positioning speed: 50 [pulses/s]
- Configuration axis 2 positioning speed: 200/100 × 50 = 100 [pulses/s]
- Vector velocity: $\sqrt{(50^2 + 100^2)} = 111.8$ [pulses/s]

The positioning speed and the vector velocity of the configuration axis 2 become a value that exceeds the velocity limit value "55" of configuration axis 1.

Circular interpolation control

For the circular interpolation, the control is performed so that the positioning speed on the circular path becomes the specified speed.

During Blending of the multiple axes positioning control

Basic operation is based on Blending during multiple axes operation. For Blending during multiple axes operation, refer to the following.

☞ Page 561 Multiple start during multiple axes operation

This section describes operation when selecting BlendingLow, BlendingPrevious, BlendingNext, and BlendingHigh in Buffer mode (BufferMode) of the motion control FB and setting different speed mode to the Velocity mode (VelocityMode) of the first FB (FB1) and the second FB (FB2) in the multiple axes positioning control.

- Multiple start is possible even when Velocity mode (VelocityMode) is different between FB1 and FB2. However, during Blending, Multiple start velocity mode specified mismatch warning (error code: 0D11H) occurs.
- The control is carried out using the FB1 Velocity mode (VelocityMode) in FB1 and using the FB2 Velocity mode (VelocityMode) in FB2.
- During Blending of FB1 and FB2, the speed is not converted by the speed mode. The positioning speed value as the FB1 speed mode is used for Blending in the positioning speed as the FB2 speed mode.
- Note that the speed of each axis and the vector velocity may rapidly change when Velocity mode (VelocityMode) of FB1 and FB2 is different during Blending.

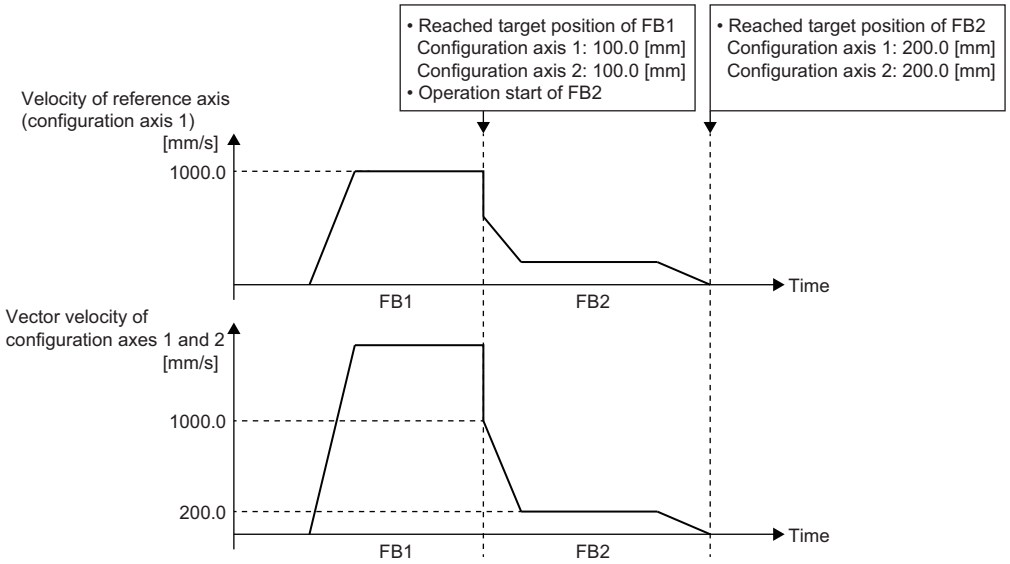
■Operation for BlendingPrevious

Blending from the reference axis velocity specification to the vector velocity specification is as shown below.
It operates so that the FB1 reference axis velocity becomes the speed set to Velocity (Velocity) of FB1 (the reference axis velocity) at the FB1 target position. The reference axis velocity when reaching the FB1 target position is read as the current vector velocity value of FB2 without unit conversion, and it accelerates/decelerates the vector velocity set in Velocity (Velocity) of FB2.

Ex.

When FB1 and FB2 are set to the following

- Axis setting, Axes group setting



Setting item	Setting value
Position and velocity command unit of the configuration axis 1	mm/s
Position and velocity command unit of the configuration axis 2	mm/s
Position and velocity command unit of the axes group	mm/s

- FB1 input (MCv_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control)) (Command unit: mm/s)

Setting item	Setting value
Linear interpolation axes (LinearAxes[0])	1
Linear interpolation axes (LinearAxes[1])	2
Linear interpolation axes (LinearAxes[2])	0
Target position (Position[0])	100.0
Target position (Position[1])	100.0
Velocity (Velocity)	1000.0
Velocity mode (VelocityMode)	2: Reference Axis Velocity (ReferenceAxisSpeed)

- FB2 input (MCv_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control)) (Command unit: mm/s)

Setting item	Setting value
Linear interpolation axes (LinearAxes[0])	1
Linear interpolation axes (LinearAxes[1])	2
Linear interpolation axes (LinearAxes[2])	0
Target position (Position[0])	200.0
Target position (Position[1])	200.0
Velocity (Velocity)	200.0
Velocity mode (VelocityMode)	0: Vector Velocity (VectorSpeed)
Buffer mode (BufferMode)	3: BlendingPrevious(mcBlendingPrevious)

- Reaches the target position of FB1 at a reference axis velocity of 1000.0 [mm/s] of configuration axis 1 that is the reference axis, and switches to FB2.
- FB2 starts operation at the vector velocity of 1000.0 [mm/s].
- Decelerates to the vector velocity of 200.0 [mm/s].
- Performs positioning to the target position of FB2.

■Operation for BlendingNext

FB1: Reference axis velocity → FB2: Vector velocity

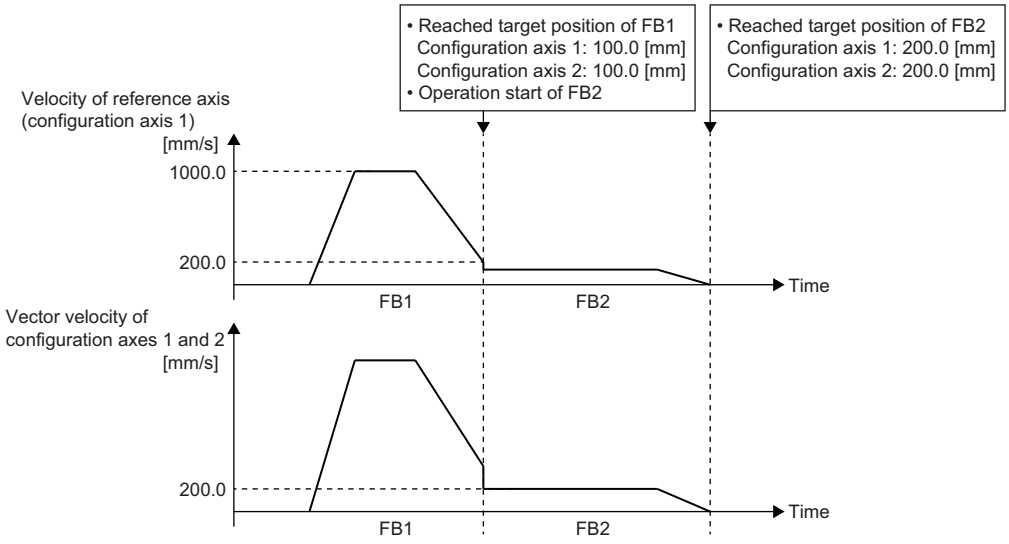
It operates so that the FB1 reference axis velocity becomes the speed set to Velocity (Velocity) of FB2 (the vector velocity) at the FB1 target position.

The reference axis velocity when reaching the FB1 target position is read as the current vector velocity value of FB2 without unit conversion, and it accelerates/decelerates the vector velocity set in Velocity (Velocity) of FB2.

Ex.

When FB1 and FB2 are set to the following

- Axis setting, Axes group setting



Setting item	Setting value
Position and velocity command unit of the configuration axis 1	mm/s
Position and velocity command unit of the configuration axis 2	mm/s
Position and velocity command unit of the axes group	mm/s

- FB1 input (MCv_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control)) (Command unit: mm/s)

Setting item	Setting value
Linear interpolation axes (LinearAxes[0])	1
Linear interpolation axes (LinearAxes[1])	2
Linear interpolation axes (LinearAxes[2])	0
Target position (Position[0])	100.0
Target position (Position[1])	100.0
Velocity (Velocity)	1000.0
Velocity mode (VelocityMode)	2: Reference Axis Velocity (ReferenceAxisSpeed)

- FB2 input (MCv_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control)) (Command unit: mm/s)

Setting item	Setting value
Linear interpolation axes (LinearAxes[0])	1
Linear interpolation axes (LinearAxes[1])	2
Linear interpolation axes (LinearAxes[2])	0
Target position (Position[0])	200.0
Target position (Position[1])	200.0
Velocity (Velocity)	200.0
Velocity mode (VelocityMode)	0: Vector Velocity (VectorSpeed)
Buffer mode (BufferMode)	4: NextBlendingNext(mcBlending)

- Operates to the middle of positioning to the target position of FB1 at a reference axis velocity of 1000.0 [mm/s] of configuration axis 1.
- Configuration axis 1 as a reference axis reaches the target position of FB1 at a reference axis velocity of 200.0 [mm/s], and switches to FB2.
- FB2 starts operation at a vector velocity of 200.0 [mm/s].
- Performs positioning to the target position of FB2.

Command unit in the multiple axes positioning control

Command unit of the multiple axes positioning control

The command unit in the multiple axes positioning control differs depending on Velocity mode (VelocityMode) of the motion control FB. For details and precautions, refer to the following.

☞ Page 490 Units

☞ Page 561 Multiple start during multiple axes operation

During Blending of the multiple axes positioning control

Basic operation is based on Blending during multiple axes operation. For Blending during multiple axes operation, refer to the following.

☞ Page 561 Multiple start during multiple axes operation

This section describes operation when selecting BlendingLow, BlendingPrevious, BlendingNext, and BlendingHigh in Buffer mode (BufferMode) of the motion control FB, and the command unit is different between the first FB (FB1) and the second FB (FB2) in the multiple axes positioning control.

- Multiple start is possible even when the command unit of FB1 and FB2 is different. However, during Blending, Velocity command unit mismatch warning (error code: 0D1EH) occurs.
- The control is carried out using the FB1 command unit in FB1 and using the FB2 command unit in FB2.
- During Blending of FB1 and FB2, the speed is not converted by the command unit mode. The positioning speed value as the FB1 command unit is used for Blending in the positioning speed as the FB2 command unit.

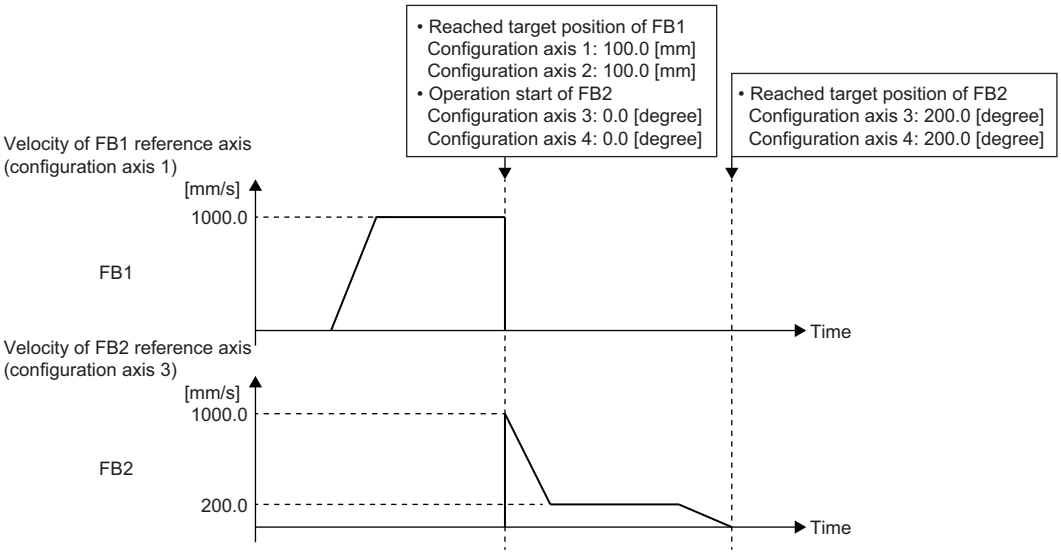
■Operation for BlendingPrevious

During Blending, multiple start is possible even when the command unit of FB1 and FB2 is different. Unit conversion is not carried out, and the speed value of FB1 is given as the speed of FB2.

Ex.

When FB1 and FB2 are set to the following

- Axis setting



Setting item	Setting value
Position and velocity command unit of the configuration axis 1	mm/s
Position and velocity command unit of the configuration axis 2	mm/s
Position and velocity command unit of the configuration axis 3	degree/min
Position and velocity command unit of the configuration axis 4	degree/min

- FB1 input (MCv_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control)) (Command unit: mm/s from the command unit of the configuration axis 1)

Setting item	Setting value
Linear interpolation axes (LinearAxes[0])	1
Linear interpolation axes (LinearAxes[1])	2
Linear interpolation axes (LinearAxes[2])	0
Target position (Position[0])	100.0
Target position (Position[1])	100.0
Velocity (Velocity)	1000.0
Velocity mode (VelocityMode)	2: Reference Axis Velocity (ReferenceAxisSpeed)

- FB2 input (MCv_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control)) (Command unit: degree/min from the command unit of the configuration axis 3)

Setting item	Setting value
Linear interpolation axes (LinearAxes[0])	3
Linear interpolation axes (LinearAxes[1])	4
Linear interpolation axes (LinearAxes[2])	0
Target position (Position[2])	200.0
Target position (Position[3])	200.0
Velocity (Velocity)	200.0
Velocity mode (VelocityMode)	2: Reference Axis Velocity (ReferenceAxisSpeed)
Buffer mode (BufferMode)	3: BlendingPrevious(mcBlendingPrevious)

- Configuration axis 1 as a reference axis reaches the target position of FB1 at a velocity of 1000.0 [mm/s], and switches to FB2.
- For FB2, configuration axis 3 as a reference axis starts operation at a velocity of 1000.0 [degrees/min].
- Configuration axis 3 as a reference axis decelerates to a velocity of 200.0 [degrees/min].
- Performs positioning to the target position of FB2.

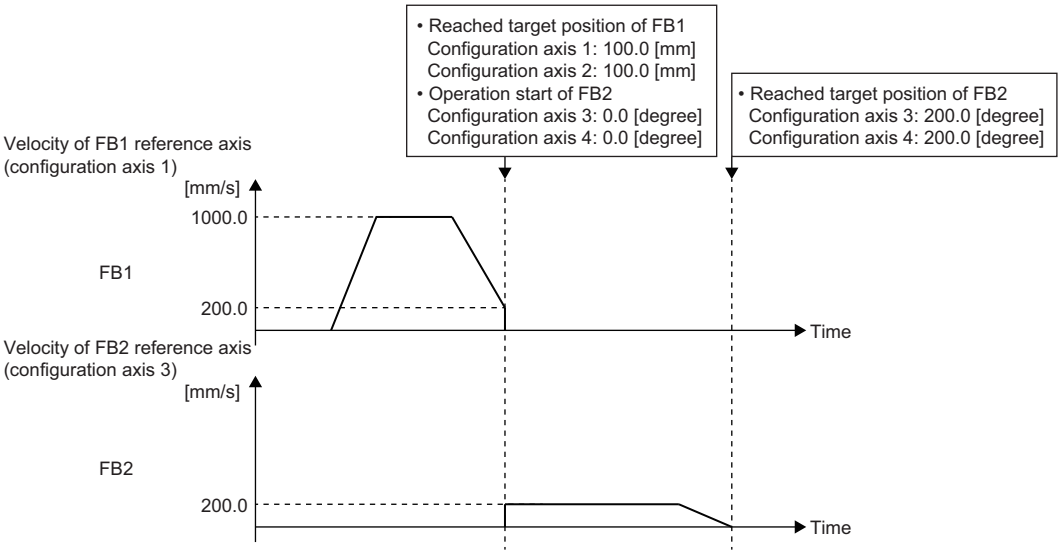
■Operation for BlendingNext

During Blending, multiple start is possible even when the command unit of FB1 and FB2 is different. Unit conversion is not carried out, and the speed value of FB1 is given as the speed of FB2.

Ex.

When FB1 and FB2 are set to the following

- Axis setting



Setting item	Setting value
Position and velocity command unit of the configuration axis 1	mm/s
Position and velocity command unit of the configuration axis 2	mm/s
Position and velocity command unit of the configuration axis 3	degree/min
Position and velocity command unit of the configuration axis 4	degree/min

- FB1 input (MCv_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control)) (Command unit: mm/s)

Setting item	Setting value
Linear interpolation axes (LinearAxes[0])	1
Linear interpolation axes (LinearAxes[1])	2
Linear interpolation axes (LinearAxes[2])	0
Target position (Position[0])	100.0
Target position (Position[1])	100.0
Velocity (Velocity)	1000.0
Velocity mode (VelocityMode)	2: Reference Axis Velocity (ReferenceAxisSpeed)

- FB2 input (MCv_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control)) (Command unit: degree/min)

Setting item	Setting value
Linear interpolation axes (LinearAxes[0])	3
Linear interpolation axes (LinearAxes[1])	4
Linear interpolation axes (LinearAxes[2])	0
Target position (Position[2])	200.0
Target position (Position[3])	200.0
Velocity (Velocity)	200.0
Velocity mode (VelocityMode)	2: Reference Axis Velocity (ReferenceAxisSpeed)
Buffer mode (BufferMode)	4: NextBlendingNext(mcBlending)

- Configuration axis 1 as a reference axis operates to the middle of positioning to the target position of FB1 at a velocity of 1000.0 [mm/s].
- Configuration axis 1 as a reference axis reaches the target position of FB1 at a velocity of 200.0 [mm/s], and switches to FB2.
- For FB2, configuration axis 3 as a reference axis starts operation at a velocity of 200.0 [degrees/min].
- Performs positioning to the target position of FB2.

Acceleration/deceleration processing

Basic operation is based on the acceleration/deceleration processing function. For the acceleration/deceleration processing function, refer to the following.

☞ Page 1078 Acceleration/Deceleration Processing Function

By Velocity mode (VelocityMode) of the motion control FB, the relationship between the positioning speed and the acceleration/deceleration processing is as shown below.

• 0: Vector Velocity (VectorSpeed)

The acceleration/deceleration processing is applied to the vector velocity.

• 1: Long Axis Velocity (LongAxisSpeed)

The acceleration/deceleration processing is applied to the long axis velocity.

• 2: Reference Axis Velocity (ReferenceAxisSpeed)

The acceleration/deceleration processing is applied to the reference axis velocity.

State transition in the multiple axes positioning control

Axes Group Status (AxesGroupName.Md.GroupStatus) of the axes group in the positioning control is "5: Operating (GroupMoving)". For Axes Group Status (AxesGroupName.Md.GroupStatus), refer to the following.

☞ Page 480 Axes group state transition

Linear interpolation control

Linear interpolation control specifies an axes group and performs interpolation control so that the path from the start point (move start point) to the end point becomes a straight line. In linear interpolation control, interpolation control using a maximum of 4 axes is performed.

Linear interpolation control includes the following two control methods.

Linear interpolation control	Description
Absolute value linear interpolation control	Specifies the target position of the absolute position, and executes linear interpolation control.
Relative value linear interpolation control	Specifies the relative movement amount from the current position, and executes linear interpolation control.

For motion control FBs that can perform each control, refer to the following.

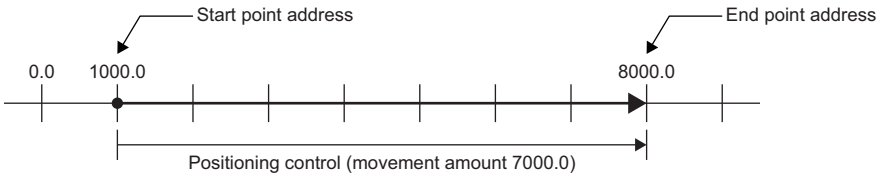
☞ Page 636 Relevant FB

Linear interpolation control operation for each number of interpolation axes is shown below.

1-axis linear interpolation control

■1-axis linear interpolation control (absolute value)

1-axis linear interpolation is executed from the current position at start (start point address) to the address (end point address) set in Target position (Position).



Ex.

When start point address of configuration axis 1 is "1000.0" and Target position (Position) is set to "8000.0"

LinearAxes[0]: 1

(LinearAxes[1]: 0)

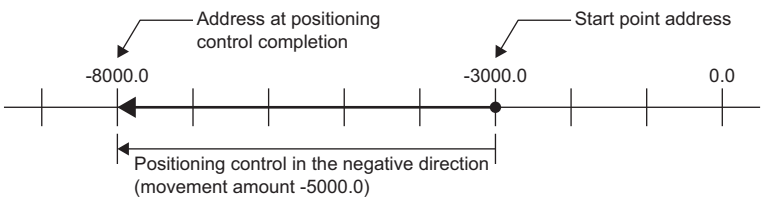
Position[0]: 8000.0

■1-axis linear interpolation control (relative value)

1-axis linear interpolation is executed by the movement amount set to Movement amount (Distance) from the current position at start (start point address).

The movement direction is determined by a sign (+/-) of the movement amount.

Movement amount	Description
Positive (+)	Positioning in the positive direction (address increasing direction)
Negative (-)	Positioning in the negative direction (address decreasing direction)



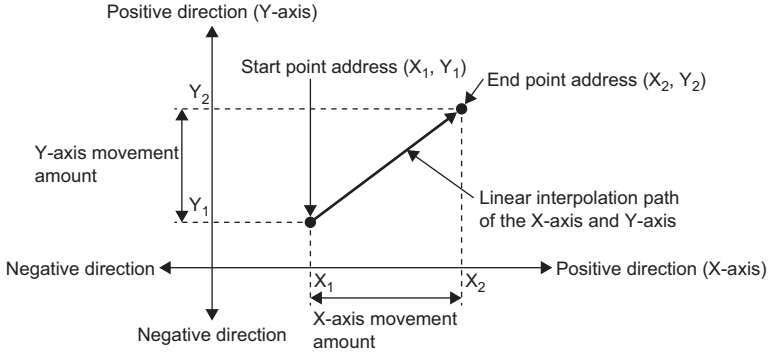
Ex.

When start point address of configuration axis 1 is "-3000.0" and Movement amount (Distance) is set to "-5000.0"

LinearAxes[0]: 1

(LinearAxes[1]: 0)

Distance[0]: -5000.0



2-axis linear interpolation control

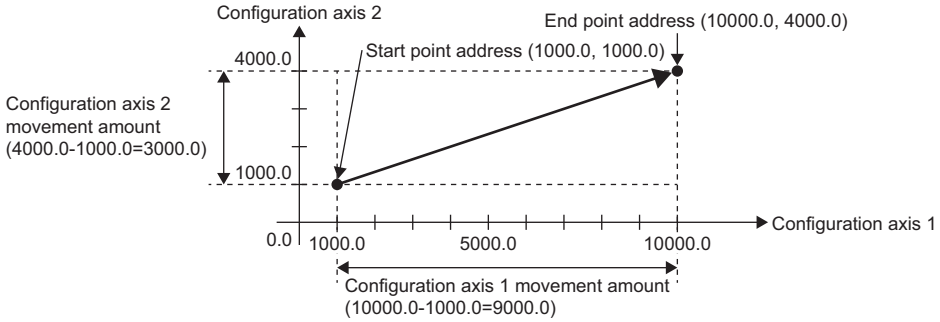
■2-axis linear interpolation control (absolute value)

2-axis linear interpolation is executed from the current position at start (start point address) to the address (end point address) set in Target position (Position).

The movement direction is determined by the start point address and the end point address of each axis.

Ex.

When the start point position is set to the configuration axis 1 "1000.0" and configuration axis 2 "1000.0" and Target position (Position) is set to the configuration axis 1 "10000.0" and configuration axis 2 "4000.0"



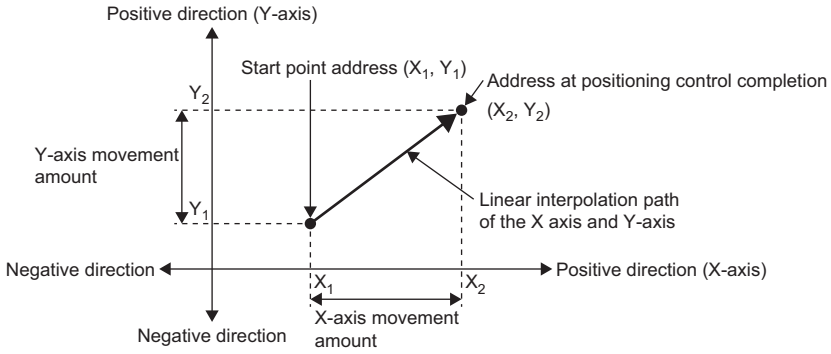
LinearAxes[0]: 1

LinearAxes[1]: 2

(LinearAxes[2]: 0)

Position[0]: 10000.0

Position[1]: 4000.0



■2-axis linear interpolation control (relative value)

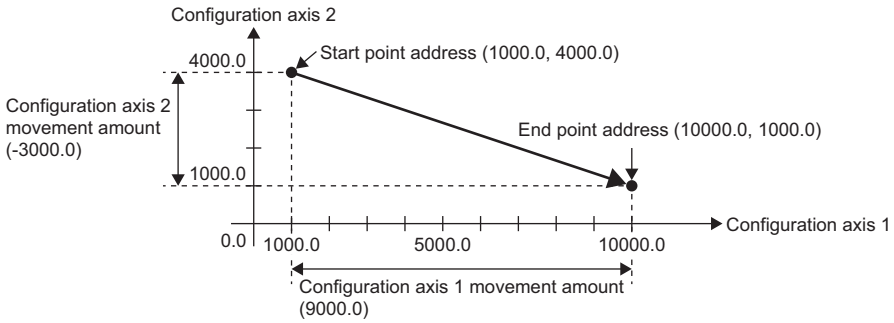
2-axis linear interpolation is executed by the movement amount set to Movement amount (Distance) from the current position at start (start point address).

The movement direction is determined by a sign (+/-) of the movement amount of each axis.

Movement amount	Description
Positive (+)	Positioning in the positive direction (address increasing direction)
Negative (-)	Positioning in the negative direction (address decreasing direction)

Ex.

When the start position is set to the configuration axis 1 "1000.0" and configuration axis 2 "4000.0" and Movement amount (Distance) is set to the configuration axis 1 "9000.0" and configuration axis 2 "-3000.0"



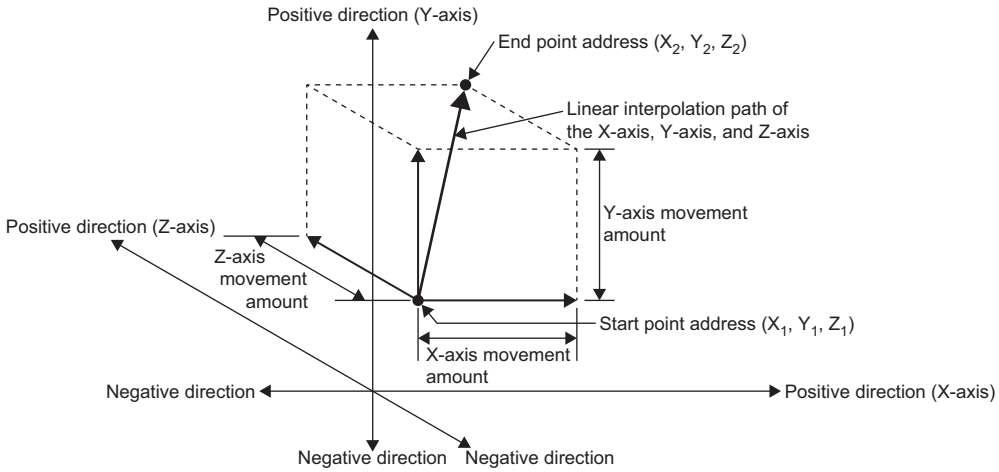
LinearAxes[0]: 1

LinearAxes[1]: 2

(LinearAxes[2]: 0)

Distance[0]: 9000.0

Distance[1]: -3000.0



3-axis linear interpolation control

■3-axis linear interpolation control (absolute value)

3-axis linear interpolation is executed from the current position at start (start point address) to the commanded position (end point address) set in Target position (Position).

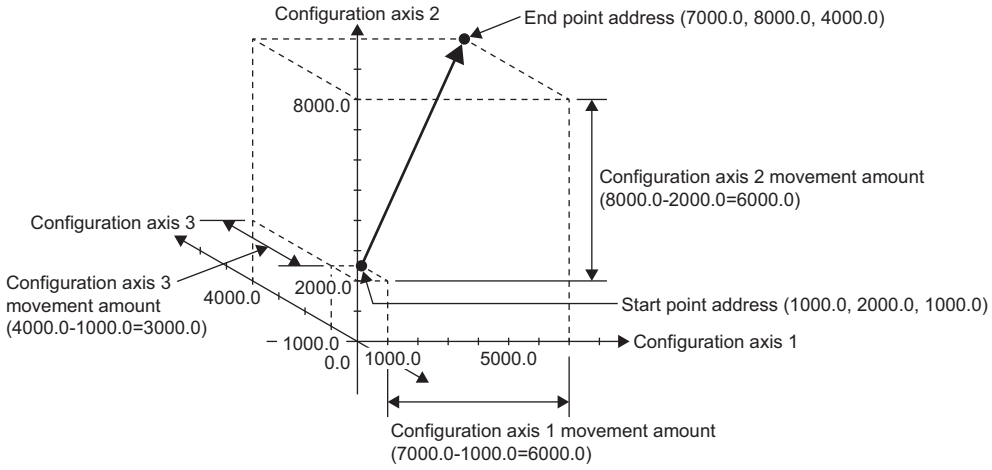
The movement direction is determined by the start point address and the end point address of each axis.

Ex.

When the start position is set to the configuration axis 1 "1000.0", configuration axis 2 "2000.0", and configuration axis 3 "1000.0" and Target position (Position) is set to the configuration axis 1 "7000.0", configuration axis 2 "8000.0", and configuration axis 3 "4000.0"

LinearAxes[0]: 1

LinearAxes[1]: 2



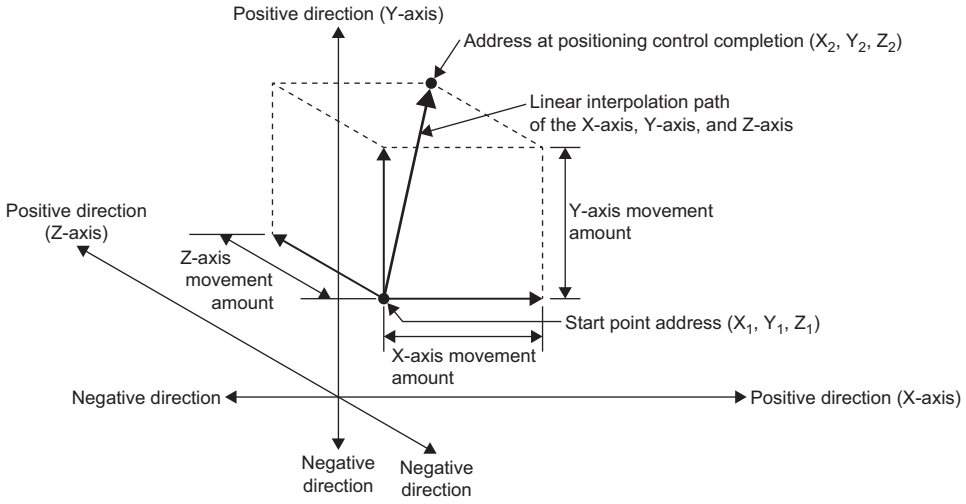
LinearAxes[2]: 3

(LinearAxes[3]: 0)

Position[0]: 7000.0

Position[1]: 8000.0

Position[2]: 4000.0



■3-axis linear interpolation control (relative value)

3-axis linear interpolation is executed by the movement amount set to Movement amount (Distance) from the current position at start (start point address).

The movement direction is determined by a sign (+/-) of the movement amount of each axis.

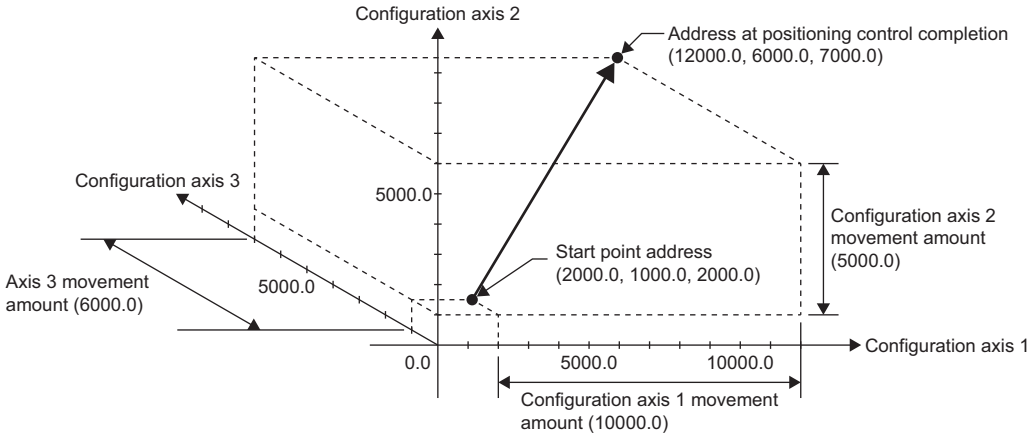
Movement amount	Description
Positive (+)	Positioning in the positive direction (address increasing direction)
Negative (-)	Positioning in the negative direction (address decreasing direction)

Ex.

When the start position is set to the configuration axis 1 "2000.0", configuration axis 2 "1000.0", and configuration axis 3 "1000.0" and Movement amount (Distance) is set to the configuration axis 1 "10000.0", configuration axis 2 "5000.0", and configuration axis 3: "6000.0"

LinearAxes[0]: 1

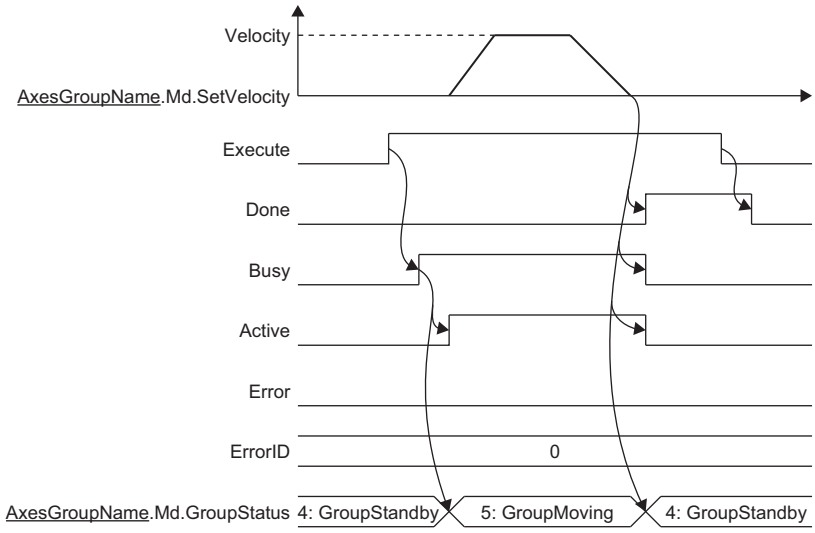
LinearAxes[1]: 2



LinearAxes[2]: 3

(LinearAxes[3]: 0)

Distance[0]: 12000.0



Distance[1]: 6000.0

Distance[2]: 7000.0

Timing chart

■When the operation completes normally

■When an error occurs

For details when an error occurs, refer to "Basic operation of Execution command (Execute) type motion control FBs" in the following manual.

MELSEC MX Controller MX-R Model Programming Manual

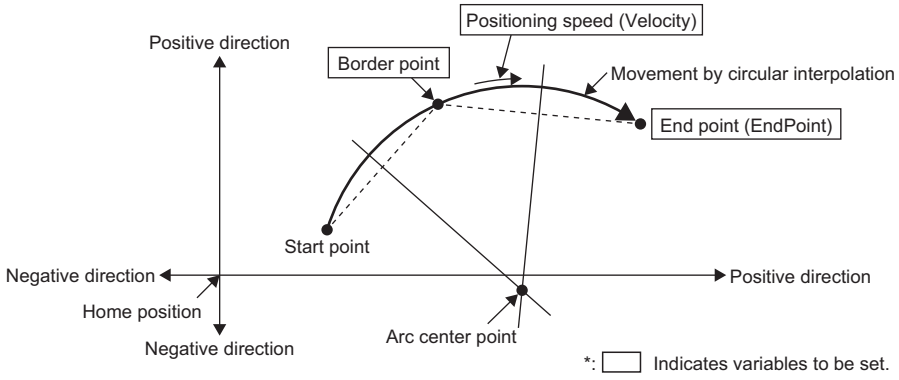
Circular interpolation control

Circular interpolation control specifies an axes group and performs interpolation control so that the path from the start point (move start point) to the end point becomes an arc to a linear axis which is arranged mechanically orthogonally.
In circular interpolation control, interpolation control can be performed using two arbitrary axes from the configuration axes set to the axes group.
Circular interpolation control includes the following two control methods.

Circular interpolation control	Description
Absolute value circular interpolation control	Specifies the end point and the sub point of the absolute position, and executes 2-axis circular interpolation control.
Relative value circular interpolation control	Specifies the end point and the movement amount of the sub point from the current position, and executes 2-axis circular interpolation control.

For motion control FBs that can perform each control, refer to the following.
☞ Page 636 Relevant FB
The following circular interpolation method can be specified with Circular interpolation mode (CircMode) for circular interpolation control.

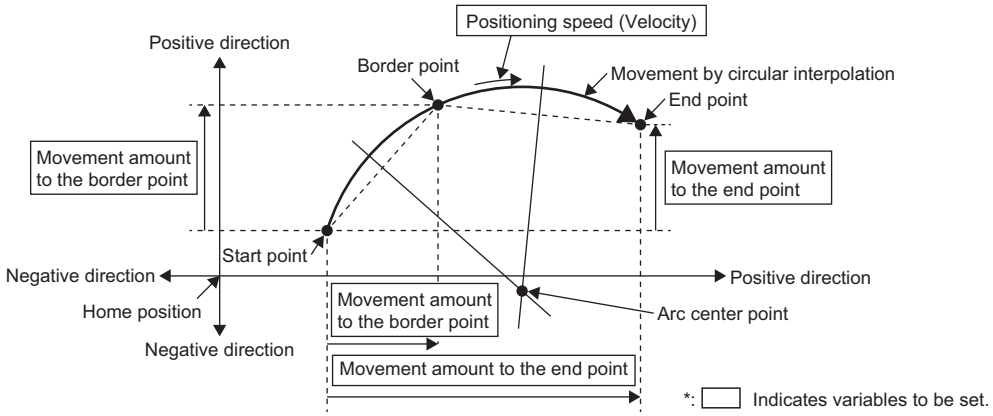
Circular interpolation method	Description	Reference
Border point specification	Positioning control is carried out in an arc path passing through the specified border point by using two configuration axes specified in Circular interpolation axes (CircAxes).	Page 655 Border point specification
Central point specification	Two configuration axes specified in Circular interpolation axes (CircAxes) are used to perform positioning control in an arc path having the specified center point as a center point.	Page 657 Center point specification
Radius specification	Two configuration axes specified in Circular interpolation axes (CircAxes) are used to perform positioning control in an arc path having the specified radius.	Page 660 Radius specification



The operations of circular interpolation control with each circular interpolation mode are shown below.

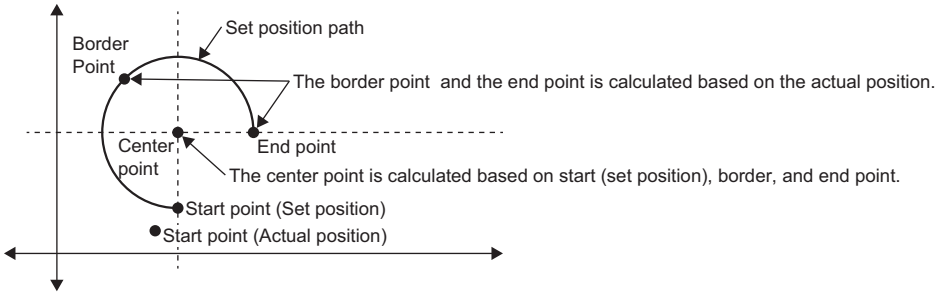
Border point specification

Positioning control is carried out in an arc path passing through the specified border point by using two configuration axes specified in Circular interpolation axes (CircAxes).



■Border point specification circular interpolation control (absolute value)

In absolute value circular interpolation control with border point specification, positioning is carried out from the current position at start (start point address) to the address (end point address) set in End point (EndPoint) in an arc path that passes through the address (border point address) set to Sub point (AuxPoint).
The resulting control path is an arc having as its center the intersection point of perpendicular bisectors of a straight line between the current position at start and the border point address, and a straight line between the border point address and the end point address. However, a perfect circle cannot be drawn with the border point specification.



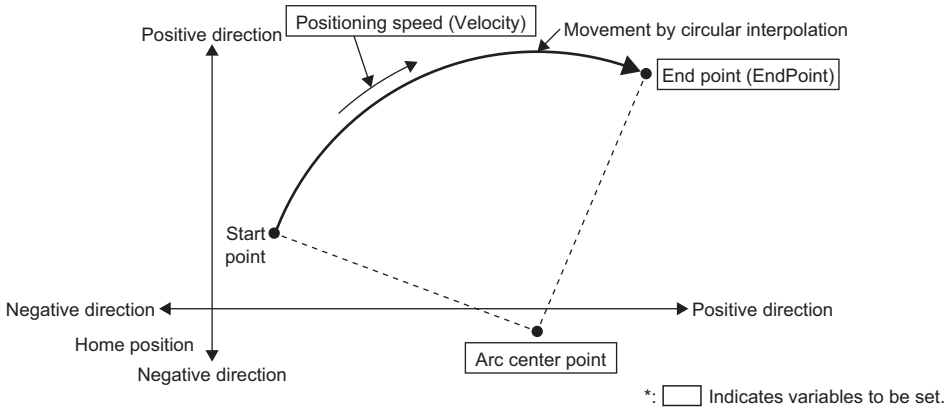
■Border point specification circular interpolation control (relative value)

In relative value circular interpolation control with border point specification, positioning is carried out from the current position at start (start point address) to the address of the movement amount (end point address) set in End point (EndPoint) in an arc path that passes through the address of the movement amount (border point address) set in Sub point (AuxPoint).
The resulting control path is an arc having as its center the intersection point of perpendicular bisectors of a straight line between the current position at start and the border point address, and a straight line between the border point address and the end point address.

- When "actual position" is selected in position selection during buffer mode (Options (Options): bit3) of relative value circular interpolation control, the border point and the end point are calculated based on the actual position. The center point is determined from the start point (set position), the border point, and the end point.

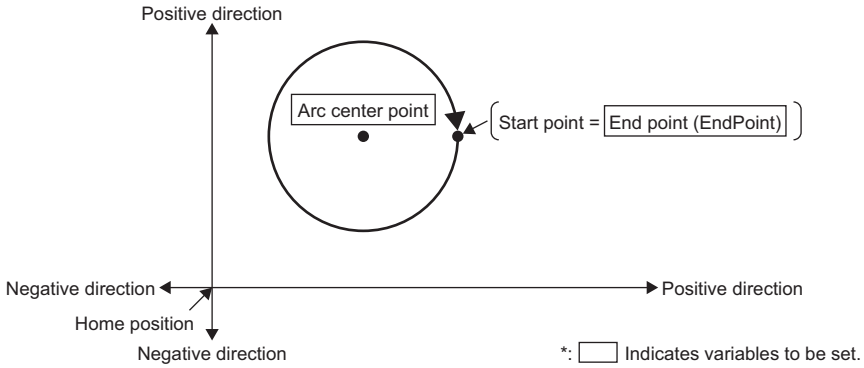
Restriction

2-axis circular interpolation control with border point specification cannot be set in the following cases.



- When the radius exceeds "2147483647.0" (the maximum radius for which 2-axis circular interpolation control is possible): (Out of radius range (error code: 1AD4H))
- When the border point address exceeds positioning range: (Out of boundary point address range (error code: 1ACCH))
- When the end point address exceeds positioning range: (Out of end point address range (error code: 1AD5H))
- When the start point address, border point address, and end point address are in the same straight line: (Start point - Boundary point - End point address same straight line (error code: 1AD2H))
- When the start point address is the same as the end point address: (Start point - End point address same value (error code: 1ACEH))
- When the start point address is the same as the border point address: (Start point - Boundary point address same value (error code: 1AD0H))
- When the end point address is the same as the border point address: (End point - Boundary point address same value (error code: 1AD1H))

Center point specification



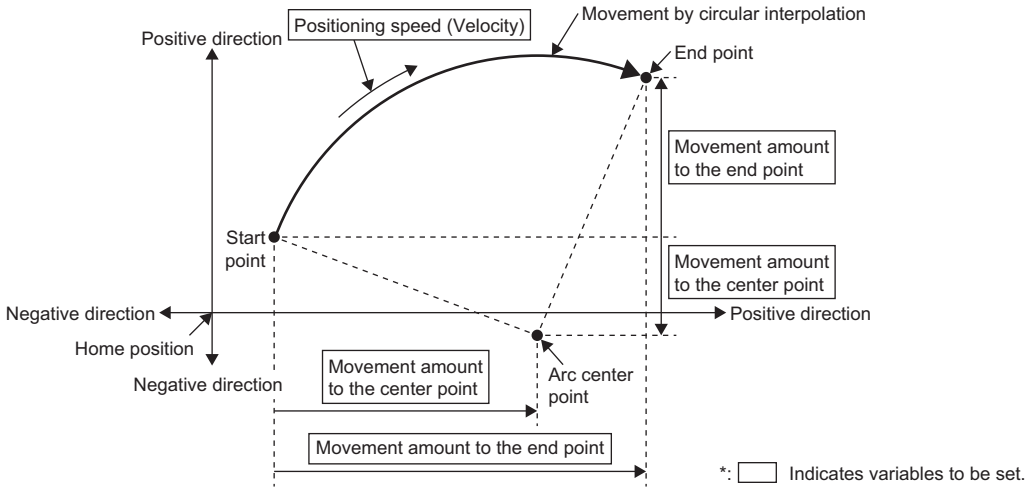
Two configuration axes specified in Circular interpolation axes (CircAxes) are used to perform positioning control in an arc path having the specified center point as a center point.

■Central point specification circular interpolation control (absolute value)

In absolute value circular interpolation control with center point specification, positioning is carried out from the current position at start (start point address) to the end position set in End point (EndPoint) in an arc path having the center point set in Sub point (AuxPoint) as its center. For absolute value circular interpolation control with center point specification, the path is set using Path selection (PathChoice). For details, refer to the following.

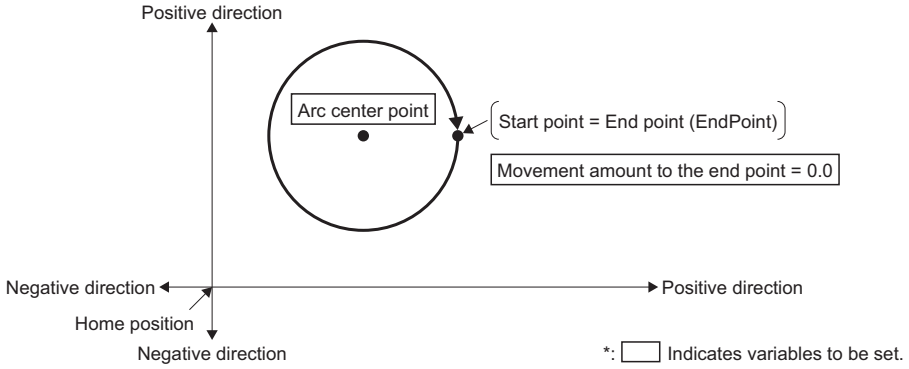
- To perform positioning for a perfect circle with a radius from the start point to the arc center point, set End point (EndPoint) the same as the start point. Setting the end point in End point (EndPoint) to the same value as the start point causes the end point and the start point to be identical.

Ex.



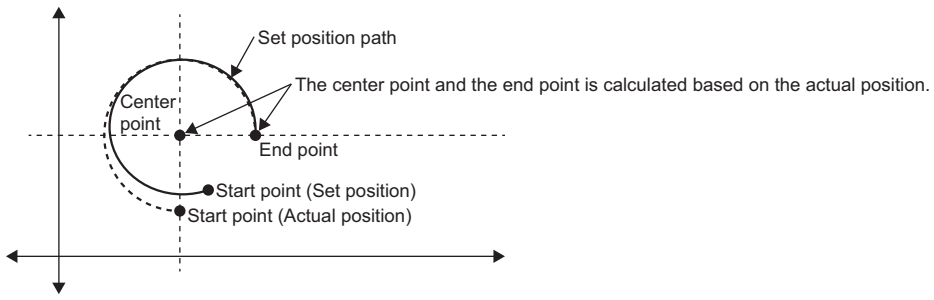
When End point (EndPoint) is set to the same value as the start point

```
AxesGroup001.Pr.Axis[1]:= Axis0001.AxisRef;
AxesGroup001.Pr.Axis[2]:= Axis0002.AxisRef;
EndPoint[0]:= Axis0001.Md.SetPosition;
EndPoint[1]:= Axis0002.Md.SetPosition;
```



Specify the set position of the configuration axes to be used in circular interpolation to End point (EndPoint) as shown above.

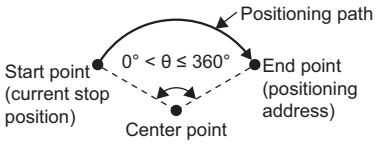
■Central point specification circular interpolation control (relative value)

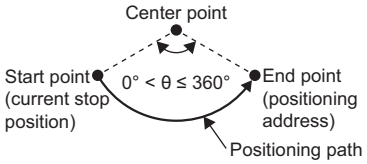


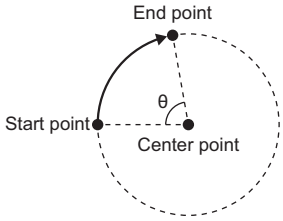
In relative value circular interpolation control with center point specification, positioning is carried out from the current position at start (start point address) to the address of the movement amount (end point address) set in End point (EndPoint) in an arc path having the address of the movement amount (center point address) set in Sub point (AuxPoint) as its center. For relative value circular interpolation control with center point specification, the path is set using Path selection (PathChoice). For details, refer to the following.

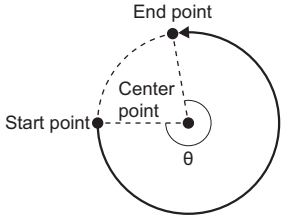
- Setting the movement amount to the end point as "0.0" in End point (EndPoint) causes the end point and the start point to be identical and performs positioning for a perfect circle with a radius from the start point to the arc center point.

- When "actual position" is selected in position selection during buffer mode (Options (Options): bit 3) of relative value circular interpolation control, the center point and the end point are calculated based on the actual position. The circular path may be ellipse.









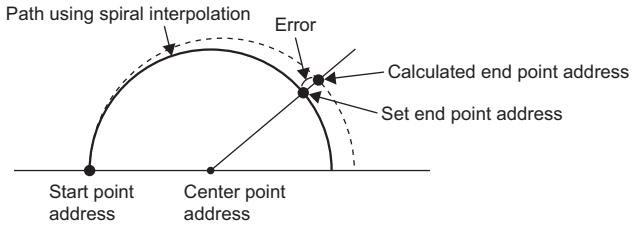
Restriction

2-axis circular interpolation control with center point specification cannot be set in the following cases.

- When the radius exceeds "2147483647.0" (the maximum radius for which 2-axis circular interpolation control is possible): (Out of radius range (error code: 1AD4H))
- When the center point address exceeds positioning range. (Out of center point address range (error code: 1AD3H))
- When the start point address is the same as the center point address. (Start point - Center point address same value (error code: 1ACDH))
- When the end point address is the same as the center point address. (End point - Center point address same value (error code: 1ACFH))

■Path of central point specification circular interpolation control

For circular interpolation control with center point specification, the path is set using Path selection (PathChoice). The setting value, setting description, arc center angle that can be controlled, and path of Path selection (PathChoice) are shown below.



Setting value	Setting description	Arc center angle that can be controlled	Path
0: CW (mcCW)	CW	$0° < \theta \leq 360°$	
1: CCW (mcCCW)	CCW	$0° < \theta \leq 360°$	
2: Shortcut (mcShortWay)	Shortcut • When the start point, center point, and end point are on one straight line, the direction becomes CW. (A semicircle is drawn in the CW direction.) • When the start point is the same as the end point, Path choice setting incorrect (error code: 1B06H) occurs.	$0° < \theta \leq 180°$	
3: Detour (mcLongWay)	Detour • When the start point, center point, and end point are on one straight line, the direction becomes CW. (A semicircle is drawn in the CW direction.) • When the start point is the same as the end point, the direction becomes CW. (A perfect circle is drawn in CW direction.)	$180° \leq \theta \leq 360°$	

■Circular interpolation error tolerance

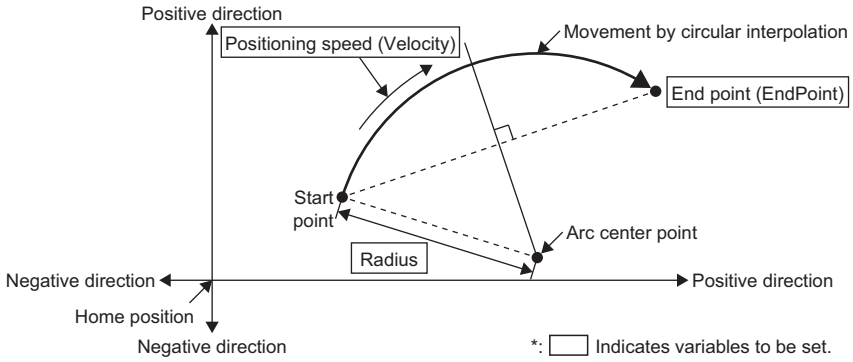
In central point specification circular interpolation control, the arc path calculated from the start position and center point position may deviate from the end position set in End point (EndPoint). Circular interpolation error tolerance (CircularErrorTolerance) sets allowable range of an error between the calculated arc path and the end position.

• Calculated error ≤ Circular interpolation error tolerance (CircularErrorTolerance)

Circular interpolation control to the set end point address is carried out while the error compensation is carried out by spiral interpolation.

• Calculated error > Circular interpolation error tolerance (CircularErrorTolerance)

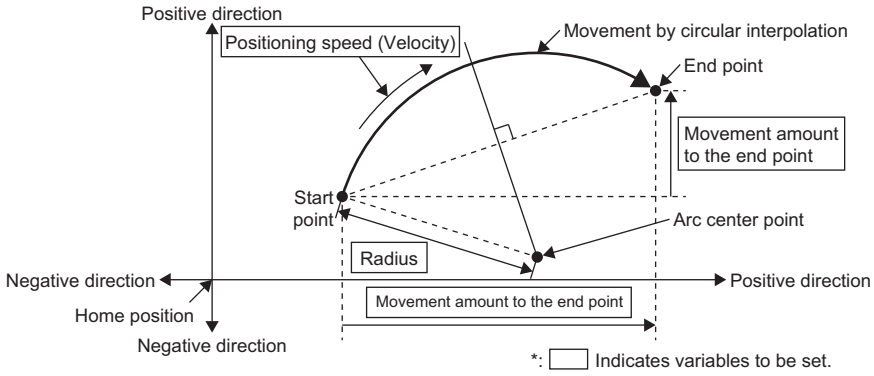
At the positioning start, Circular interpolation error allowable value over (error code: 1AD9H) occurs and the control will not start. The machine will immediately stop if the error is detected during positioning control.



Radius specification

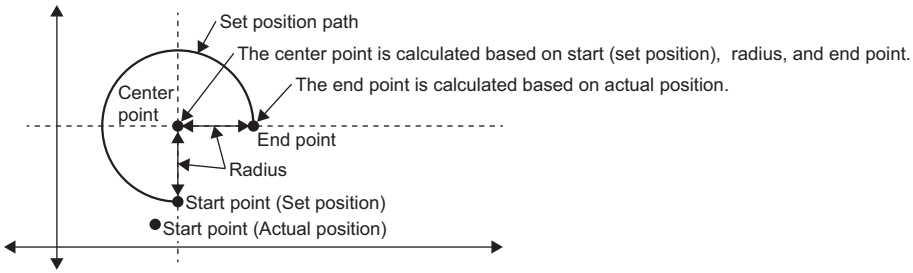
Two configuration axes specified in Circular interpolation axes (CircAxes) are used to perform positioning control in an arc path having the specified radius.

■Radius specification circular interpolation control (absolute value)



In absolute value circular interpolation control with radius specification, positioning is carried out from the current position at start (start point address) to the address (end point address) set in End point (EndPoint) in a path having the radius set in Sub point (AuxPoint). The resulting control path is an arc with the intersection of the perpendicular bisector of the current position at start and the end point address, and the specified radius as the center point.

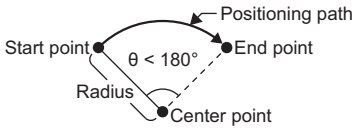
For absolute value circular interpolation control with radius specification, the path is set using Path selection (PathChoice). For details, refer to the following.

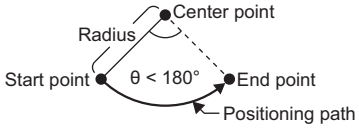


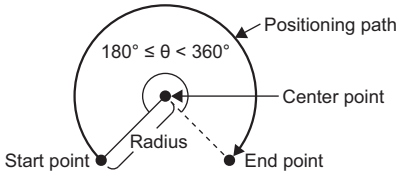
■Radius specification circular interpolation control (relative value)

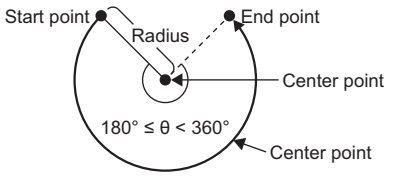
In relative value circular interpolation control with radius specification, positioning is carried out from the current position at start (start point address) to the address of the movement amount (end point address) set in End point (EndPoint) in a path having the radius set in Sub point (AuxPoint). The resulting control path is an arc with the intersection of the perpendicular bisector of the current position at start and the end point address, and the specified radius as the center point.
For relative value circular interpolation control with radius specification, the path is set using Path selection (PathChoice). For details, refer to the following.

- When "actual position" is selected in position selection during buffer mode (Options (Options): bit 3) of relative value circular interpolation control, the end point is calculated based on the actual position. The center point is determined by the start point (set position), radius, and end point.





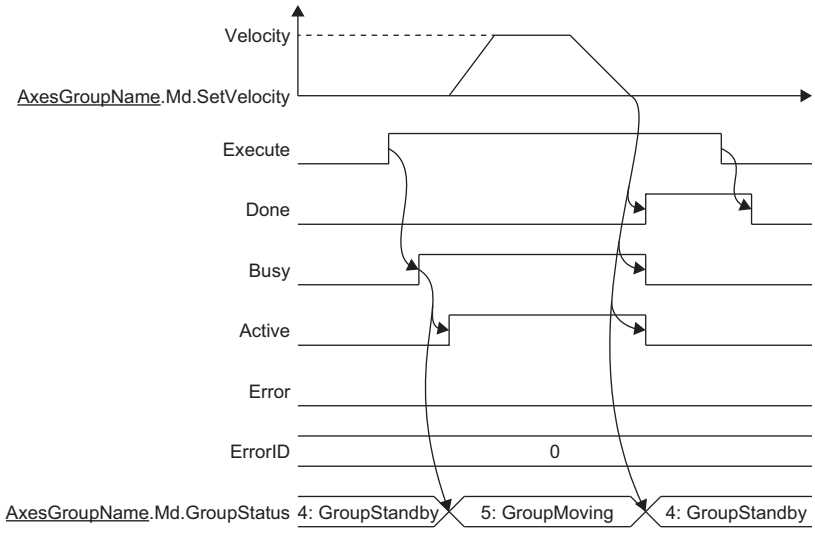




Restriction

2-axis circular interpolation control with radius specification cannot be set in the following cases.

- When the radius exceeds "2147483647.0" (the maximum radius for which 2-axis circular interpolation control is possible): (Out of radius range (error code: 1AD4H))
- When the end point address exceeds positioning range: (Out of end point address range (error code: 1AD5H))
- When the start point address is the same as the end point address: (Start point - End point address same value (error code: 1ACEH))
- When the distance between the start point address and the end point address is larger than the radius. (Radius setting error (error code: 1AD6H))



■Path of radius specification circular interpolation control

For circular interpolation control with radius specification, the path is set using Path selection (PathChoice). The setting value, setting description, arc center angle that can be controlled, and path of Path selection (PathChoice) are shown below.

Setting value	Setting description	Arc center angle that can be controlled	Path
0: CW (mcCW)	CW Shortcut • When the start point, center point, and end point are on one straight line, Path choice setting incorrect (error code: 1B06H) occurs.	0° < θ < 180°	
1: CCW (mcCCW)	CCW Shortcut • When the start point, center point, and end point are on one straight line, Path choice setting incorrect (error code: 1B06H) occurs.	0° < θ < 180°	
4: CW Detour (mcCWLongWay)	CW Detour • The start point, center point, and end point are on one straight line, a semicircle is drawn.	180° ≤ θ < 360°	
5: CCW Detour (mcCCWLongWay)	CCW Detour • The start point, center point, and end point are on one straight line, a semicircle is drawn.	180° ≤ θ < 360°	

Timing chart

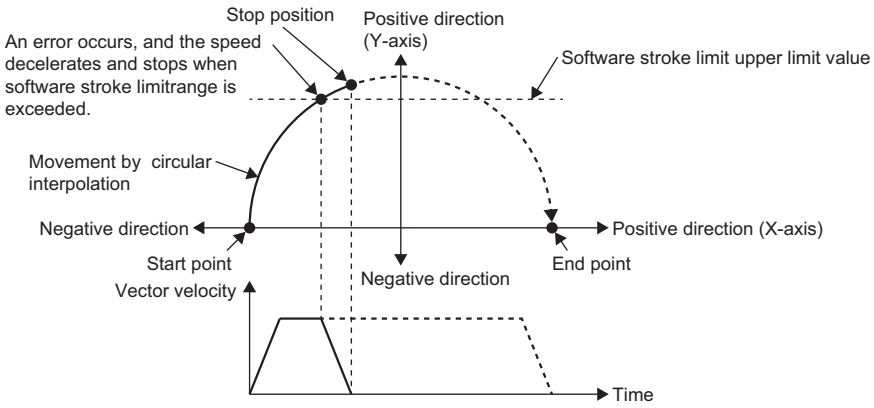
■When the operation completes normally

■When an error occurs

For details when an error occurs, refer to "Basic operation of Execution command (Execute) type motion control FBs" in the following manual.

MELSEC MX Controller MX-R Model Programming Manual

Precautions



- Circular interpolation including an axis whose stroke limit is set to invalid cannot be carried out. Software stroke limit invalid at circular interpolation (error code: 1ADAH) occurs and the operation does not start.
- When the interpolation path exceeds the stroke limit range during interpolation operation, Software stroke limit over (forward direction) (error code: 1A83H) or Software stroke limit over (reverse direction) (error code: 1A84H) occurs and the operation will stop.

Ex.

When the upper limit of the software stroke limit is exceeded in the positive direction of the Y-axis

For an immediate stop, the operation stops at the same time that the error occurs.

For a deceleration stop, the operation decelerates to a stop along the arc path as shown below.

Required object data

When using multiple axes positioning control, map the object assigned to the following object data to PDO for all configuration axes in the specified axes group.

• Target position (607AH)

If there is a configuration axis that does not map the above object to PDO, Required object data unset (error code: 1AF7H) will occur and the operation will not start.

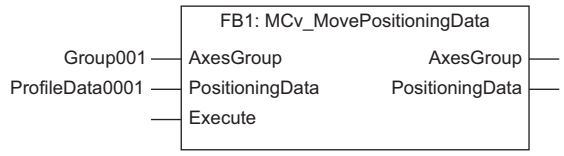
For details on the object data settings, refer to the following.

☞ Page 466 Axis Assignment

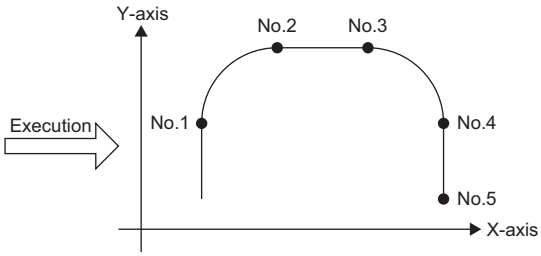
28.5 Multiple Axes Positioning Data Operation

This function executes positioning for the axes group with the specified positioning method and speed to the preset passing point in one start. The positioning method and speed can be changed for each passing point.
Among the configuration axes of the axes group, interpolation operation of 1 to 4 axes can be executed.
The following parameters are set in the operation profile data (multiple axes positioning data format). For details on the operation profile data, refer to the following.
☞ Page 849 Multiple axes positioning data

- Set position address of passing point
- Control method from any passing point to the next passing point
- Velocity from any passing point to the next passing point



Point



By using multiple axes positioning data operation, continuous multiple axes positioning operation can be executed without describing the user program that executes the positioning control FB with multiple start.

<Operation profile data (multiple axes positioning data format)>

Overall block diagram

The relationship between the data used in multiple axes positioning data operation and other functions is shown below.

*1 For the relationship with operation profile data, refer to the following.
☞ Page 824 Overall block diagram

Relevant variable

MC_POSITIONING_DATA_ID

Variable/structure name	Name	Details
ProfileID	Profile ID	Sets the operation profile data ID. Profile ID (ProfileID) is PROFILE_ID structure.

Relevant FB

For details on motion control FBs, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

Motion control FB	Name	Description
MCv_MovePositioningData	Multiple axes positioning data operation	Operates the axes group according to the specified positioning data.

Control details

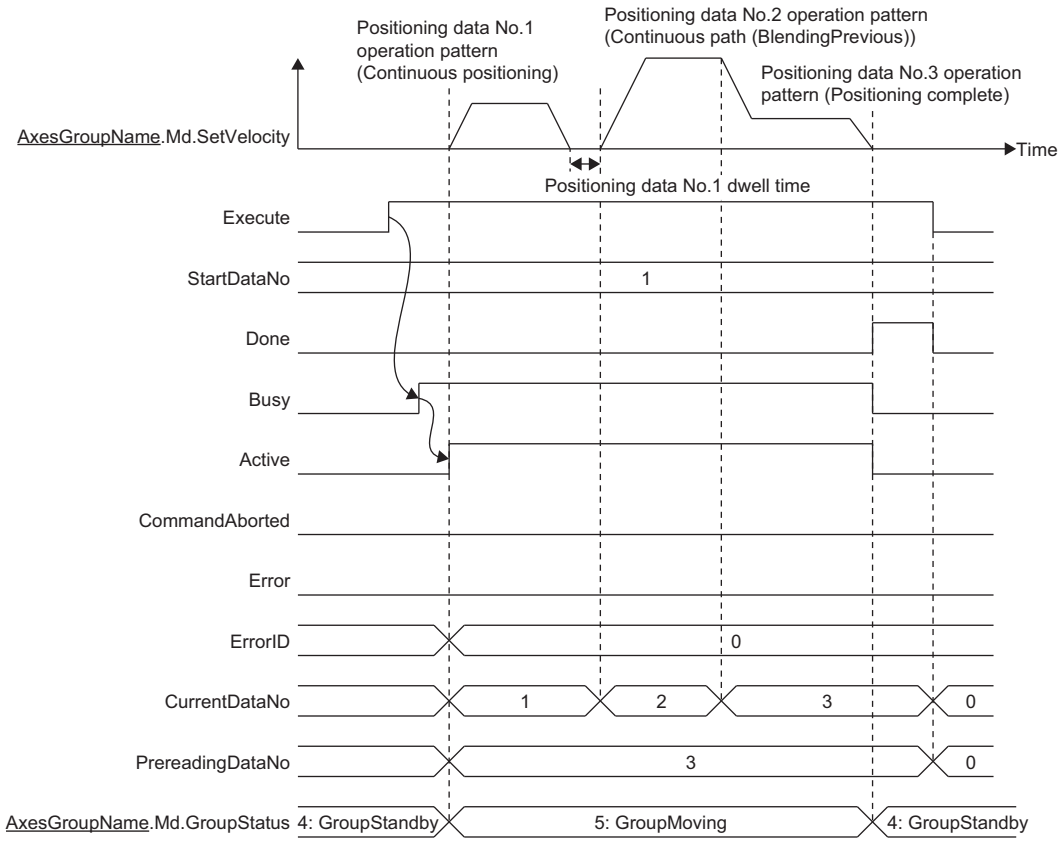
- A function to execute continuous positioning operation specified in the operation profile data (multiple axes positioning data format) for the axes group.
- This function is executed by MCv_MovePositioningData (multiple axes positioning data operation).
- Before using this function, axes group needs to be set and enabled. For details, refer to the following.

☞ Page 478 Axes Group
☞ Page 487 Axes Group Assignment

- Before using this function, it is necessary to open the operation profile data of multiple axes positioning data format to the open area and set to a state where it can be controlled. For details on the operation profile data format and the operation of the operation profile data, refer to the following.

☞ Page 824 Operation Profile Data

- For multiple axes positioning data operation, the positioning data is read from the start positioning data No. (StartDataNo) in ascending order, and the multiple axes positioning operation is executed internally and continuously. For details, refer to the following.



☞ Page 668 Positioning data setting

Timing chart

Axes Group Status (AxesGroupName.Md.GroupStatus) of the axes group during control is "5: Operating (GroupMoving)". For the axes group status, refer to the following.

☞ Page 480 Axes group state transition

■When the operation completes normally

■When an error occurs

For details when an error occurs, refer to "Basic operation of Execution command (Execute) type motion control FBs" in the following manual.

MELSEC MX Controller MX-R Model Programming Manual

Positioning data setting

This section describes the positioning operation of multiple axes positioning data operation by positioning data settings. The positioning data is set in the operation profile data (multiple axes positioning data format). For details on the operation profile data (multiple axes positioning data format), refer to the following.

☞ Page 849 Multiple axes positioning data

Positioning data to be set

The positioning data to be set differs depending on the Control method (ControlMethod). The positioning data that can be set is shown below.

◎: Setting required, ○: Setting as necessary, —: Setting not required (There is no problem if the value is within the setting range such as the initial value)

Variable name	Name	Control method (ControlMethod)					
		Linear interpolation	Circular interpolation	NOP	JUMP	LOOP	LEND
DataNo	Positioning data No.	◎	◎	◎	◎	◎	◎
OperationPattern	Operation pattern	◎	◎	—	—	—	—
ControlMethod	Control method	◎	◎	◎	◎	◎	◎
InterpolationAxis1 to InterpolationAxis4	Interpolation axis 1 to Interpolation axis 4	◎*1	◎*2	—	—	—	—
CircMode	Circular interpolation mode	—	◎	—	—	—	—
CircPathChoice	Path selection	—	◎	—	—	—	—

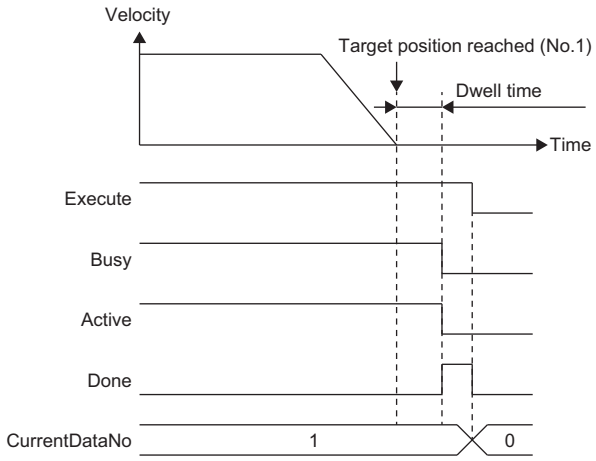
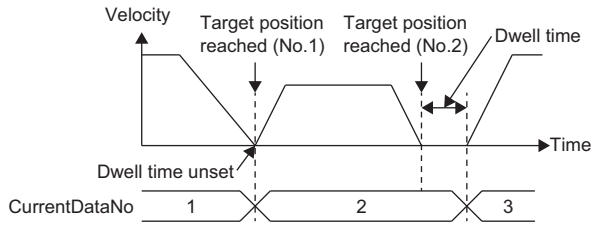
SkipSignalNo	Skip signal No.	○	○	—	—	—	—
Pitch	Pitch	—	—	—	—	—	—

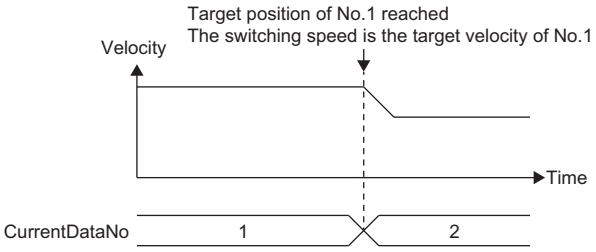
*1 It is as follows according to the number of axes of the configuration axis to be set.
◎: Setting required, —: Setting not required

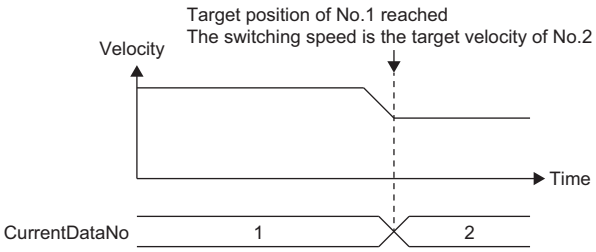
Variable name	Name	1 axis	2 axes	3 axes	4 axes
InterpolationAxis1	Interpolation axis 1	◎	◎	◎	◎
InterpolationAxis2	Interpolation axis 2	—	◎	◎	◎
InterpolationAxis3	Interpolation axis 3	—	—	◎	◎
InterpolationAxis4	Interpolation axis 4	—	—	—	◎
Position1	Target position/Movement amount/End point 1	◎	◎	◎	◎
Position2	Target position/Movement amount/End point 2	—	◎	◎	◎
Position3	Target position/Movement amount/End point 3	—	—	◎	◎
Position4	Target position/Movement amount/End point 4	—	—	—	◎

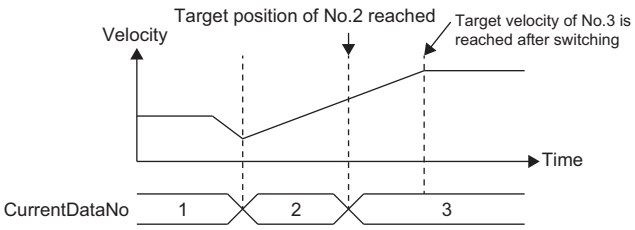




*2 Interpolation axis 3 (InterpolationAxis3), Interpolation axis 4 (InterpolationAxis4), Target position/Movement amount/End point 3 (Position3), Target position/Movement amount/End point 4 (Position4), Sub point 3 (CircAuxPoint3), and Sub point 4 (CircAuxPoint4) become "—: Setting not required".







■Positioning data No. (DataNo)

- The positioning data No. sets the index number of the positioning data.
- MCv_MovePositioningData (multiple axes positioning data operation) executes the positioning data in the order of positioning data No. (DataNo). It sets the positioning data so that the positioning data No. (DataNo) is in ascending order.
- For multiple axes positioning data operation, the positioning data is read from the start positioning data No. (StartDataNo) in ascending order, and the multiple axes interpolation operation is executed internally and continuously.
- Set whether to execute or not to execute the next positioning data in the operation pattern. (☞ Page 670 Operation pattern (OperationPattern))
- In multiple axes positioning data operation, the empty (unset) positioning data No. cannot be used. If the unset positioning data No. is executed in multiple axes positioning data operation, Out of setting range of operation profile data in multiple axes positioning data format (error code: 1B35H) will occur at the time of reading the corresponding positioning data.
- The setting range is "1 to total number of positioning data".

■Operation pattern (OperationPattern)

- Set whether to execute the positioning data after the specified data continuously or not.
- In positioning continue data, the positioning data of the next data No. is automatically executed. The operation pattern (OperationPattern) of positioning data that is the final positioning operation is set to "0: Positioning complete (PositioningComplete)" to complete multiple axes positioning data operation.
- For positioning continue data, the operation is continued until it reaches the positioning complete data. Therefore, if there is no positioning complete data, the operation is executed up to the positioning data No. of the total number of positioning data, and the operation will be executed again from positioning data No.1.
- There are the following types of operation patterns (OperationPattern). The type that can be set differs depending on the Control method (ControlMethod).

Positioning continue/ complete	Setting value	Description
Complete	0: Positioning complete (PositioningComplete)	• The positioning of the specified one data is executed and multiple axes positioning data operation is completed when the target position is reached. • When the dwell time is set, the control is completed after the set time elapses. 
Continue	1: Continuous positioning (ContinuousPositioning)	• The positioning of the next positioning data No. is executed automatically. • The next positioning is executed sequentially after the target position is reached. When the target position is reached, the operation will decelerate automatically, and after the set velocity of axes group becomes 0, the next positioning is executed. • When the dwell time is set, the next positioning is executed after the set time elapses. • When the M code is set, the next positioning is executed after the M code is reset. For details, refer to the following. ☞ Page 700 M code output function 
Continue	2: Continuous path (BlendingLow) (ContinuousBlendingLow)	• The positioning of the next positioning data No. is executed automatically. • The next positioning is executed sequentially after the target position is reached. The operation does not stop between the positioning that is being executed and the next positioning. • When the dwell time is set, the operation is the same as the continuous positioning. • The smaller target velocity between the positioning that is being executed and the next positioning is used as the switching velocity. • When the velocity of the positioning that is being executed is smaller, the operation is the same as continuous path (BlendingPrevious), and when the velocity of the next positioning is smaller, the operation is the same as continuous path (BlendingNext).

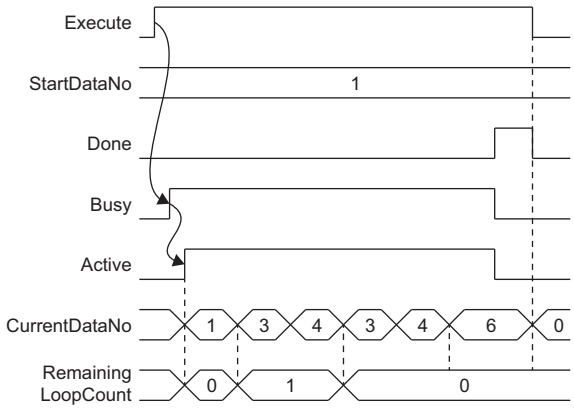
Positioning continue/ complete	Setting value	Description
Continue	3: Continuous path (BlendingPrevious) (ContinuousBlendingPrevious)	• The positioning of the next positioning data No. is executed automatically. • The next positioning is executed sequentially after the target position is reached. The operation does not stop between the positioning that is being executed and the next positioning. • When the dwell time is set, the operation is the same as the continuous positioning. • Operation is performed at the target velocity of the positioning that is being executed until the target position is reached. • When the positioning data is switched, the velocity change is executed to the target velocity of the next positioning. 
Continue	4: Continuous path (BlendingNext) (ContinuousBlendingNext)	• The positioning of the next positioning data No. is executed automatically. • The next positioning is executed sequentially after the target position is reached. The operation does not stop between the positioning that is being executed and the next positioning. • When the dwell time is set, the operation is the same as the continuous positioning. • Operation is performed so that the command velocity becomes the target velocity of the next positioning at the target position.  • Depending on the movement amount of the positioning that is being executed, the movement amount to execute the velocity change to the target velocity of the next positioning may be insufficient at the target position of the positioning that is being executed. In this case, the velocity change is started immediately, but the velocity cannot reach the target velocity of the next positioning at the target position of the positioning that is being executed. 
Continue	5: Continuous path (BlendingHigh) (ContinuousBlendingHigh)	• The positioning of the next positioning data No. is executed automatically. • The next positioning is executed sequentially after the target position is reached. The operation does not stop between the positioning that is being executed and the next positioning. • When the dwell time is set, the operation is the same as the continuous positioning. • The larger target velocity between the positioning that is being executed and the next positioning is used as the switching velocity. • When the velocity of the positioning that is being executed is larger, the operation is the same as continuous path (BlendingPrevious), and when the velocity of the next positioning is larger, the operation is the same as continuous path (BlendingNext).
Continue	— (No setting)	For the control method (NOP, JUMP, LOOP, and LEND) which does not require the setting of the operation pattern, positioning is continued, but the positioning data No. to be executed next differs depending on the control method. For details, refer to the following. ☞ Page 672 Control method (ControlMethod)

■Control method (ControlMethod)

- Set the control method of the positioning data.
- If the Control method (ControlMethod) of the positioning data specified in the positioning data No. (DataNo) is other (NOP, JUMP, LOOP, and LEND) when multiple axes positioning data operation is executed, the data is read sequentially from the start positioning data No. (StartDataNo) until the positioning data of the positioning operation (linear interpolation, circular interpolation) is read. The positioning data of the positioning operation read first becomes the positioning operation to be executed first. For the reading after the positioning data No., which executes the positioning operation first, refer to the following.

☞ Page 684 Pre-read

- There are the following types of control methods.



Positioning operation	Setting value	Description
Linear interpolation	0101H: Absolute value linear interpolation (LinearAbsolute)	The linear interpolation operation is executed by specifying the target position of the absolute position so that the path from the start point (move start point) to the end point becomes a straight line. For control details on the linear interpolation, refer to the following.*1 ☞ Page 649 Linear interpolation control
	0102H: Relative value linear interpolation (LinearRelative)	The linear interpolation operation is executed by specifying the relative movement amount from the current position so that the path from the start point (move start point) to the end point becomes a straight line. For control details on the linear interpolation, refer to the following.*1 ☞ Page 649 Linear interpolation control
Circular interpolation	0103H: Absolute value circular interpolation (CircularAbsolute)	2-axis circular interpolation operation is executed by specifying the absolute position end point and sub point so that the path from the start point (move start point) to the end point becomes an arc with respect to 2 linear axes which are orthogonally arranged mechanically. For control details on the circular interpolation, refer to the following.*1 ☞ Page 655 Circular interpolation control
	0104H: Relative value circular interpolation (CircularRelative)	2-axis circular interpolation operation is executed by specifying the end point and the movement amount of sub point from the current position so that the path from the start point (move start point) to the end point becomes an arc with respect to 2 linear axes which are orthogonally arranged mechanically. For control details on the circular interpolation, refer to the following.*1 ☞ Page 655 Circular interpolation control

Positioning operation	Setting value	Description
Others	0080H: NOP (NOP)	Move to the next positioning data No. without processing. ■NOP application example In the middle of the positioning between two points, if there is a possibility of velocity switching or temporary stop (automatic deceleration) in the future, the positioning operation can be changed by simply replacing the control method after reserving the data by NOP.
	0082H: JUMP (JUMP)	The JUMP positioning data jumps to the specified positioning data No. There are the following types of JUMP. ■JUMP with no condition • The JUMP execution conditions are not set. • Jump to the positioning data No. set to the jump destination positioning data No. (JumpDestinationDataNo) of the positioning data. • Set the condition signal No. (ConditionSignalNo) of the positioning data to "0" or omit the setting. ■Condition JUMP • The JUMP execution conditions are set. • Use the condition signal set to the condition signal No. (ConditionSignalNo) of the positioning data as the execution condition. • The execution condition uses the Condition signal 1 to Condition signal 10 (ConditionSignal1 to ConditionSignal10) of the operation profile data (multiple axes positioning data format). Set the external signal (bit input signal) to the condition signal. For details on the setting, refer to the following. ☞ Page 691 Condition signal setting • Set the number used for each positioning data from the condition signals as the condition signal No. (ConditionSignalNo). For example, set the condition signal No. (ConditionSignalNo) to "2" when the condition signal 2 (ConditionSignal2) is used. • If the condition signal set in the condition signal No. (ConditionSignalNo) is in signal input status, execution conditions are determined to be satisfied, and if the condition signal is not in signal input status, execution conditions are determined to be not satisfied. • When the execution condition is satisfied, jump to the positioning data No. set to the jump destination positioning data No. (JumpDestinationDataNo) of the positioning data. When the execution condition is not satisfied, execute the next positioning data No. without jumping. • The execution condition is determined when the corresponding positioning data whose Control method (ControlMethod) is "0082H: JUMP (JUMP)" is pre-read.
	0083H: LOOP (LOOP)	Execute the loop control by repetition (LOOP to LEND).*2 Repeat the positioning data between LOOP and LEND loops according to the number of times set to the Number of LOOP to LEND repetitions (LoopCount) of the positioning data.
	0084H: LEND (LEND)	Return to the start of the repetition (LOOP to LEND) loop.*2 The loop terminates when the loop for the number of times of the Number of LOOP to LEND repetitions (LoopCount) set in LOOP is executed. Thereafter, the positioning data of the next positioning data No. is executed. To complete the control after the repetition of the number of times of the Number of LOOP to LEND repetitions (LoopCount) is executed, set it as follows. • Set the positioning data whose operation pattern (OperationPattern) is "1: Continuous positioning (ContinuousPositioning)" to the positioning data No. before LEND. • Set the dummy positioning data (for example, relative value linear interpolation with movement amount 0) to the next positioning data No. of LEND.

*1 The following specifications are different for positioning operations (linear interpolation, circular interpolation).

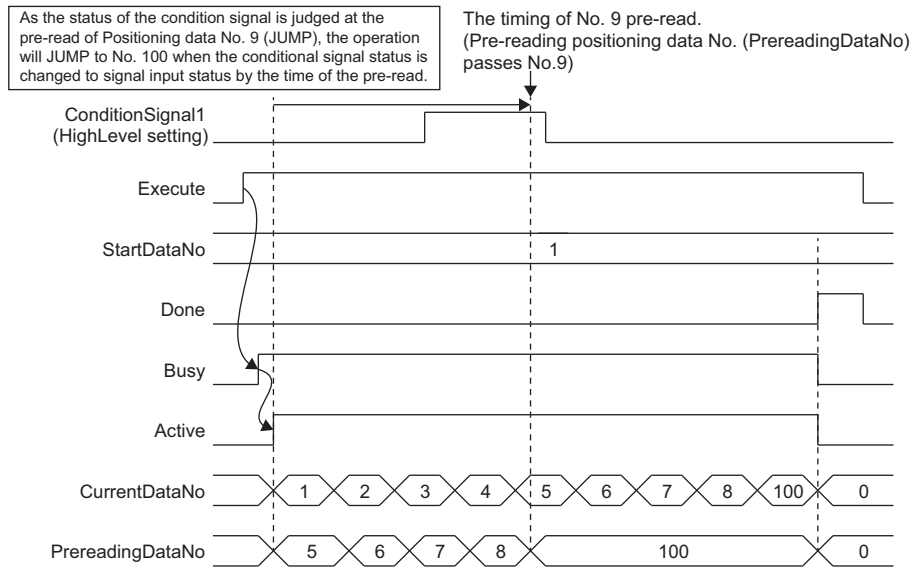
Function	Description
Control change function	There is no control change function by restart/continuous update. Use the override function when executing control change of the target velocity, acceleration/deceleration, or acceleration/deceleration time. For details on the override function, refer to the following. ☞ Page 690 Override function ☞ Page 1116 Override Function
Continuous execution of positioning data	There is no multiple start for the continuous execution of the positioning data. Use the operation pattern (OperationPattern) for the continuous execution of the positioning data.

*2 The following table lists the operation of the repetition loop with LOOP and LEND set.

Positioning data No. (DataNo)	Operation pattern (OperationPattern)	Control method (ControlMethod)	Number of LOOP to LEND repetitions (LoopCount)	Operation
1	3: Continuous path (BlendingPrevious) (ContinuousBlendingPrevious)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	The execution order is as follows: Positioning data No.1 → No.2 → No.3 → No.4 → No.5 → No.2 → No.3 → No.4 → No.5 → No.6. • Timing chart 
2	—	0083H: LOOP (LOOP)	2	
3	3: Continuous path (BlendingPrevious) (ContinuousBlendingPrevious)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	
4	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	
5	—	0084H: LEND (LEND)	—	
6	0: Positioning complete (PositioningComplete)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	

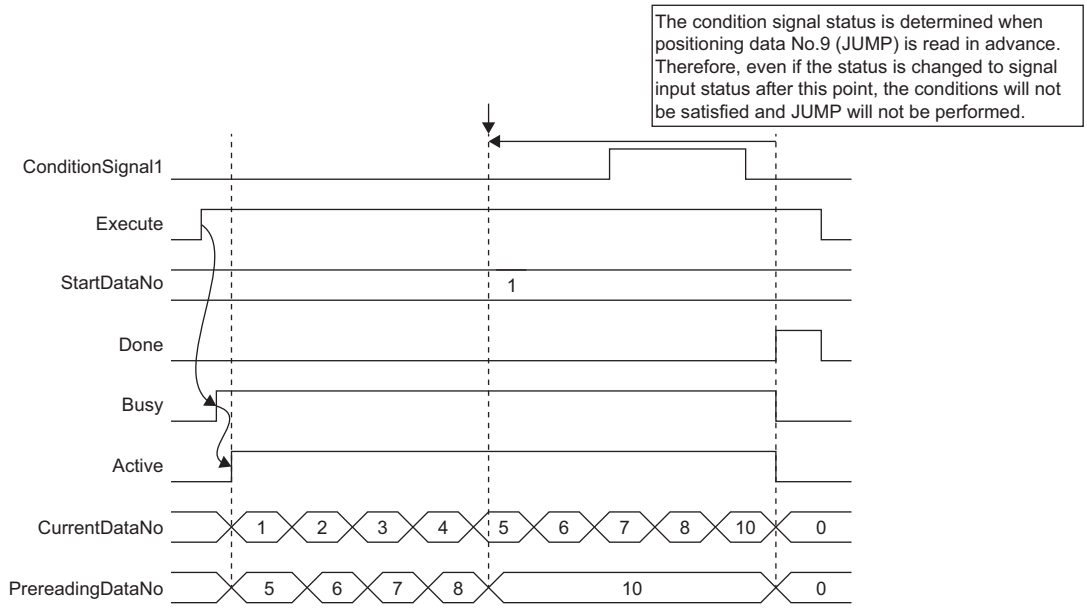
Precautions

- Set the positioning data No. of the positioning data in which the method other than JUMP is set in the jump destination positioning data No. (JumpDestinationDataNo). If the Control method (ControlMethod) of the jump destination is "0083H: JUMP (JUMP)", Multiple axes positioning data control method incorrect (error code: 1B36H) will occur when executing FB or during control.
- If the condition JUMP is used, the execution condition (signal status of condition signal) is determined when the corresponding positioning data whose Control method (ControlMethod) is "0082H: JUMP (JUMP)" is pre-read. Satisfy the execution condition before the pre-reading positioning data No. (PrereadingDataNo) passes through JUMP. If the condition is not satisfied before passing, the execution condition is regarded as not satisfied in the processing.



Ex.

When the following positioning data is set



Positioning data No. (DataNo)	Operation pattern (OperationPattern)	Control method (ControlMethod)	Jump destination positioning data No. (JumpDestinationDataNo)	Condition signal No. (ConditionSignalNo)
1	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	—
2	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	—
3	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	—
4	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	—
5	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	—
6	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	—
7	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	—

Positioning data No. (DataNo)	Operation pattern (OperationPattern)	Control method (ControlMethod)	Jump destination positioning data No. (JumpDestinationDataNo)	Condition signal No. (ConditionSignalNo)
8	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	—

10	0: Positioning complete (PositioningComplete)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	—
⋮	⋮	⋮	⋮	⋮
100	0: Positioning complete (PositioningComplete)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	—

■When the condition signal is set to the signal input status before the condition JUMP is pre-read

■When the condition signal is set to the signal input status after the condition JUMP is pre-read

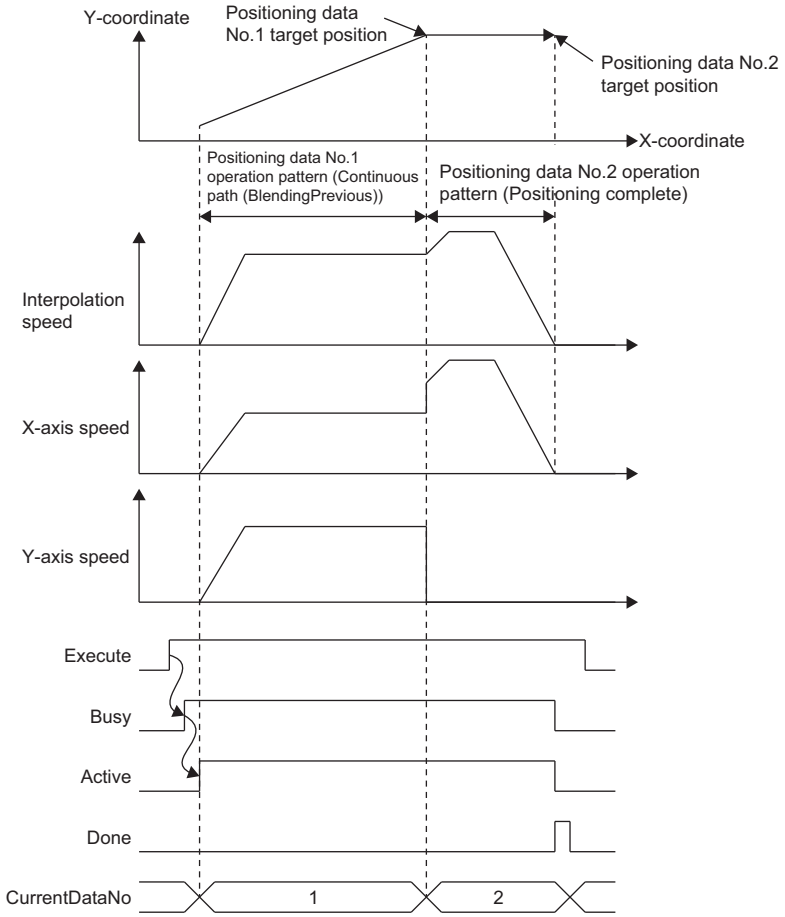
- An error does not occur even if there is no LEND after LOOP, but the loop control is not executed.
- LEND before LOOP execution is disabled.
- If there is positioning complete data between LOOP and LEND, the multiple axes positioning data operation is completed after executing the positioning data, and the loop control is not executed.

• LOOP and LEND cannot be nested between them. If nested, the loop control is executed only between the inner LOOP and LEND.

Ex.

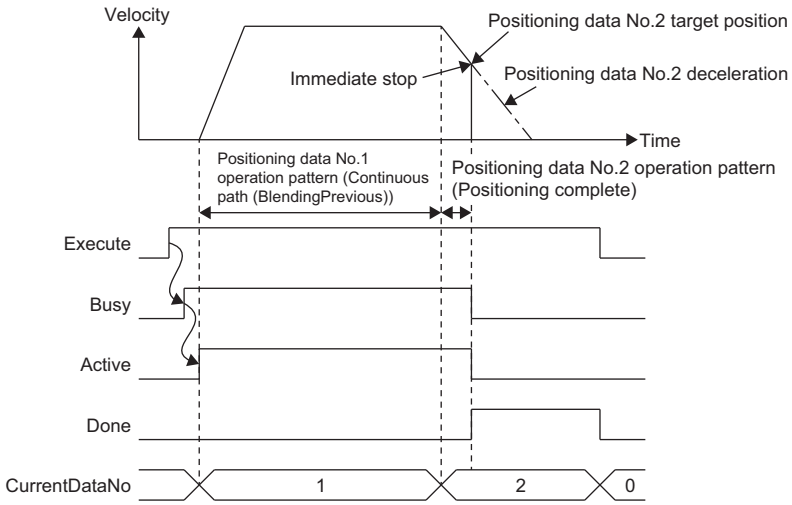
When the loop control is executed only between the inner LOOP and LEND

Positioning data No. (DataNo)	Operation pattern (OperationPattern)	Control method (ControlMethod)	Number of LOOP to LEND repetitions (LoopCount)	Operation
1	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	• The execution order is as follows: Positioning data No.1 → No.2 → No.3 → No.4 → No.5 → No.6 → No.7 → No.4 → No.5 → No.6 → No.7 → No.8 → No.9. • The settings of LOOP for positioning data No.2 and LEND for positioning data No.8 will be disabled.
2	—	0083H: LOOP (LOOP)	3	
3	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	
4	—	0083H: LOOP (LOOP)	2	
5	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	
6	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	
7	—	0084H: LEND (LEND)	—	
8	—	0084H: LEND (LEND)	—	
9	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	



• Even if JUMP is set after LOOP, the loop control is executed if there is a LEND after JUMP destination positioning data No.

Ex.



When LOOP to LEND and JUMP (JUMP with no condition) are combined

Positioning data No. (DataNo)	Operation pattern (OperationPattern)	Control method (ControlMethod)	Positioning data No. (DataNo)	Jump destination positioning data No. (JumpDestinationDataNo)	Operation
1	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	—	• The execution order is as follows: Positioning data No.1 → No.2 → No.3 → No.4 → No.101 → No.102 → No.2 → No.3 → No.4 → No.101 → No.102 → No.103. • Even if there is a LOOP or LEND in positioning data No.5 to No.100, these settings are disabled because they are not in the execution order.
2	—	0083H: LOOP (LOOP)	2	—	
3	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	—	
4	—	0082H: JUMP (JUMP)	—	101	
⋮	⋮	⋮	⋮	⋮	
101	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	—	
102	—	0084H: LEND (LEND)	—	—	
103	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	—	

- When switching from the positioning data of multiple axes interpolation data and continuous path data to the next positioning data, the interpolation velocity at the time of switching is used as the switching velocity. Therefore, acceleration/deceleration may not be executed and a rapid velocity change may occur depending on the movement amount and movement direction of each axis for the next positioning data.

- When switching from the continuous path data to positioning complete data or continuous positioning data, the deceleration distance cannot be secured after switching at the switching velocity, and the target position may be overrun. In this case, the automatic deceleration operation is executed according to the setting of Operation Setting at Overrun (AxesGroupName.Pr.OverrunOperation).

Setting value	Operation
1: Immediate Stop (ImmediateStop)	The axis starts deceleration immediately, and it stops immediately at reaching the target position after outputting Overrun Warning. 

Point

When switching to continuous positioning data and decelerating due to insufficient movement amount, the positioning of the next positioning data No. is executed after stopping the axis.

- Other (NOP, JUMP, LOOP, and LEND) positioning data has an upper limit on the number of continuous executions. Set the positioning data so that it does not exceed the upper limit of the number of continuous executions. If the upper limit is exceeded when executing FB or during control, Multiple axes positioning data control method incorrect (error code: 1B36H) will occur.

Upper limit of the number of continuous executions
100 times

Ex.

When NOP is used in positioning data No.2 to No.102

In the following cases, errors can be avoided by setting the Control method (ControlMethod) of No.2 to "0082H: JUMP (JUMP)" and jump destination positioning data No. (JumpDestinationDataNo) to "103".

Positioning data No. (DataNo)	Operation pattern (OperationPattern)	Control method (ControlMethod)	Jump destination positioning data No. (JumpDestinationDataNo)	Operation
1	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	The upper limit value is exceeded in positioning data No.2 → ... → No.102, and an error will occur.
2	—	0080H: NOP (NOP)	—	
⋮	⋮	⋮	⋮	
102	—	0080H: NOP (NOP)	—	
103	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	

Ex.

For the standby operation that loops until conditions are satisfied only with condition JUMP

Positioning data No. (DataNo)	Operation pattern (OperationPattern)	Control method (ControlMethod)	Jump destination positioning data No. (JumpDestinationDataNo)	Operation
1	—	0080H: NOP (NOP)	—	The upper limit is exceeded in positioning data No.1 → No.2 → No.1 → ... by repeating NOP and JUMP, and an error will occur.
2	—	0082H: JUMP (JUMP)	1	
3	1: Continuous positioning (ContinuousPositioning)	0101H: Absolute value linear interpolation (LinearAbsolute)	—	

Configure the user program to interlock the FB start when executing the standby operation before executing FB.

Use the M code output function when executing the standby operation with positioning data in the middle. For details on the M code output function, refer to the following.

☞ Page 700 M code output function

■Interpolation axis 1 to Interpolation axis 4 (InterpolationAxis1 to InterpolationAxis4)

- Set interpolation axes from configuration axes of the axes group.
- The setting range is 1 to 16.
- The setting details differ depending on the settings of the Control method (ControlMethod).

Control method (ControlMethod)	Description
0101H: Absolute value linear interpolation (LinearAbsolute)	Set the linear interpolation axes (LinearAxes) of the linear interpolation. For details, refer to the following. ☞ Page 649 Linear interpolation control However, read Interpolation axis 1 to Interpolation axis 4 (InterpolationAxis1 to InterpolationAxis4) as the linear interpolation axes (LinearAxes[0] to LinearAxes[3]).
0102H: Relative value linear interpolation (LinearRelative)	
0103H: Absolute value circular interpolation (CircularAbsolute)	Set the circular interpolation axes (CircAxes[0], CircAxes[1]) of the circular interpolation to Interpolation axis 1 (InterpolationAxis1) and Interpolation axis 2 (InterpolationAxis2). For details, refer to the following. ☞ Page 655 Circular interpolation control Interpolation axis 3 (InterpolationAxis3) and interpolation axis 4 (InterpolationAxis4) are not used. The setting is disabled.
0104H: Relative value circular interpolation (CircularRelative)	

- Regarding configuration axes specified as interpolation axes, a different configuration axis and the number of interpolation axes can be set for each positioning data. However, note that if the specified configuration axis or the number of interpolation axes is different between continuous path data and the next positioning data, each axis velocity may rapidly change when switching the positioning data. For the positioning speed, refer to the following.

☞ Page 686 Positioning speed

☞ Page 638 Positioning speed in multiple axes positioning control

■Circular interpolation mode (CircMode)

Set the circular interpolation method (border point specification, center point specification, and radius specification) for executing the circular interpolation control.

For details on the circular interpolation mode (CircMode), refer to the following.

☞ Page 655 Border point specification

☞ Page 657 Center point specification

☞ Page 660 Radius specification

■Path selection (CircPathChoice)

Set the rotation direction of the circular interpolation control (CW, CCW, shortcut, detour, CW detour, CCW detour).

The path selection (CircPathChoice) that can be set differs depending on the circular interpolation mode (CircMode).

For details, refer to the following.

☞ Page 659 Path of central point specification circular interpolation control

☞ Page 662 Path of radius specification circular interpolation control

■Target position/Movement amount/End point 1 to Target position/Movement amount/End point 4 (Position1 to Position4)

The setting details differ depending on the settings of the Control method (ControlMethod).

Control method (ControlMethod)	Description
0101H: Absolute value linear interpolation (LinearAbsolute)	• Set the target position of the absolute position. • Target position/Movement amount/End point 1 to Target position/Movement amount/End point 4 (Position1 to Position4) indicate the target position of the configuration axis set by Interpolation axis 1 to Interpolation axis 4 (InterpolationAxis1 to InterpolationAxis4). • Target position/Movement amount/End point 1 to Target position/Movement amount/End point 4 (Position1 to Position4) corresponding to "0" or omitted Interpolation axis 1 to Interpolation axis 4 (InterpolationAxis1 to InterpolationAxis4) can be omitted. • For the setting value, refer to MC_MoveAbsolute (Absolute Value Positioning) in the following manual. MELSEC MX Controller MX-R Model Programming Manual
0102H: Relative value linear interpolation (LinearRelative)	• Set the movement amount from the current position when the positioning data is executed. • Target position/Movement amount/End point 1 to Target position/Movement amount/End point 4 (Position1 to Position4) indicate the movement amount of the configuration axis set by Interpolation axis 1 to Interpolation axis 4 (InterpolationAxis1 to InterpolationAxis4). • Target position/Movement amount/End point 1 to Target position/Movement amount/End point 4 (Position1 to Position4) corresponding to "0" or omitted Interpolation axis 1 to Interpolation axis 4 (InterpolationAxis1 to InterpolationAxis4) can be omitted. • The setting value is "-10000000000.0 to 10000000000.0".
0103H: Absolute value circular interpolation (CircularAbsolute)	• Set the end position of the absolute position. • Target position/Movement amount/End point 1 (Position1) and Target position/Movement amount/End point 2 (Position2) indicate the target position of the configuration axis set by Interpolation axis 1 (InterpolationAxis1) and Interpolation axis 2 (InterpolationAxis2). • Target position/Movement amount/End point 3 (Position3) and Target position/Movement amount/End point 4 (Position4) can be omitted. (The setting is disabled.) • The setting value is "-10000000000.0 ≤ Setting value < 10000000000.0". * When the ring counter is enabled, it becomes the ring counter range.
0104H: Relative value circular interpolation (CircularRelative)	• Set the movement amount from the current position to the end point when the positioning data is executed. • Target position/Movement amount/End point 1 (Position1) and Target position/Movement amount/End point 2 (Position2) indicate the movement amount of the configuration axis set by Interpolation axis 1 (InterpolationAxis1) and Interpolation axis 2 (InterpolationAxis2). • Target position/Movement amount/End point 3 (Position3) and Target position/Movement amount/End point 4 (Position4) can be omitted. (The setting is disabled.) • The setting value is "-10000000000.0 to 10000000000.0".

■Direction selection 1 to Direction selection 4 (Direction1 to Direction4)

Set the direction (positive direction, negative direction, and shortest path) to be moved by linear interpolation control.

The setting details differ depending on the settings of the Control method (ControlMethod).

Control method (ControlMethod)	Description
0101H: Absolute value linear interpolation (LinearAbsolute)	• Set the movement direction (positive direction, negative direction, and shortest path) from the current position to the target position. • Direction selection 1 to Direction selection 4 (Direction1 to Direction4) indicate the direction selection of the configuration axis set by Interpolation axis 1 to Interpolation axis 4 (InterpolationAxis1 to InterpolationAxis4). • The setting value is disabled for interpolation axes with software stroke limit enabled. • The array elements of Direction selection 1 to Direction selection 4 (Direction1 to Direction4) corresponding to "0" or omitted Interpolation axis 1 to Interpolation axis 4 (InterpolationAxis1 to InterpolationAxis4) can be omitted. • For details on each direction selection, refer to MC_MoveAbsolute (Absolute Value Positioning) in the following manual. MELSEC MX Controller MX-R Model Programming Manual
0102H: Relative value linear interpolation (LinearRelative)	No setting is required. The setting value is disabled.

■Sub point 1 to Sub point 4 (CircAuxPoint1 to CircAuxPoint4)

Set the position of the sub point (boundary point, center point, and radius) to execute the circular interpolation control.
The setting details differ depending on the settings of the circular interpolation mode (CircMode).

Circular interpolation mode (CircMode)	Description
0: Border point specification (mcBorder) 1: Center point specification (mcCenter)	• Sub point 1 (CircAuxPoint1) and Sub point 2 (CircAuxPoint2) indicate the boundary point/center point of the configuration axis set by Interpolation axis 1 (InterpolationAxis1) and Interpolation axis 2 (InterpolationAxis2). Set in absolute value or relative value. • Sub point 3 (CircAuxPoint3) and Sub point 4 (CircAuxPoint4) can be omitted. (The setting is disabled.) • According to the set control method (ControlMethod), the setting range is shown below. ■0103H: Absolute value circular interpolation (CircularAbsolute) -10000000000.0 ≤ Setting value < 10000000000.0 * When the ring counter is enabled, it becomes the ring counter range. ■0104H: Relative value circular interpolation (CircularRelative) -10000000000.0 to 10000000000.0
2: Radius specification (mcRadius)	• Sub point 1 (CircAuxPoint1) indicates the radius of the arc. • Sub point 2 to Sub point 4 (CircAuxPoint2 to CircAuxPoint4) can be omitted. (The setting is disabled.) • The setting range is "0.000001 to 2147483647.0".

■Velocity mode (VelocityMode)

Set the velocity mode (vector velocity, long axis velocity, and reference axis velocity) of linear interpolation control.

The setting details differ depending on the settings of the circular interpolation mode (CircMode).

For details on the Velocity mode (VelocityMode), refer to the following.

☞ Page 638 Vector velocity specification

☞ Page 639 Long axis velocity specification

☞ Page 640 Reference axis velocity specification

■Velocity (Velocity)

Set the positioning speed for multiple axes interpolation. For details, refer to the following.

☞ Page 638 Positioning speed in multiple axes positioning control

The setting range is "0, 0.0001 to 2500000000.0".

■Acceleration (Acceleration)

Set the acceleration for multiple axes interpolation.

The setting details differ depending on the settings of acceleration/deceleration method setting (bit 0 to 2) for positioning data options (DataOptions).

For details on the acceleration/deceleration method, refer to the following.

☞ Page 1078 Acceleration/Deceleration Processing Function

■Deceleration (Deceleration)

Set the deceleration for multiple axes interpolation.

The setting details differ depending on the settings of acceleration/deceleration method setting (bit 0 to 2) for positioning data options (DataOptions).

For details on the acceleration/deceleration method, refer to the following.

☞ Page 1078 Acceleration/Deceleration Processing Function

■Jerk (Jerk)

Set the jerk for multiple axes positioning control.

The setting details differ depending on the settings of acceleration/deceleration method setting (bit 0 to 2) for positioning data options (DataOptions).

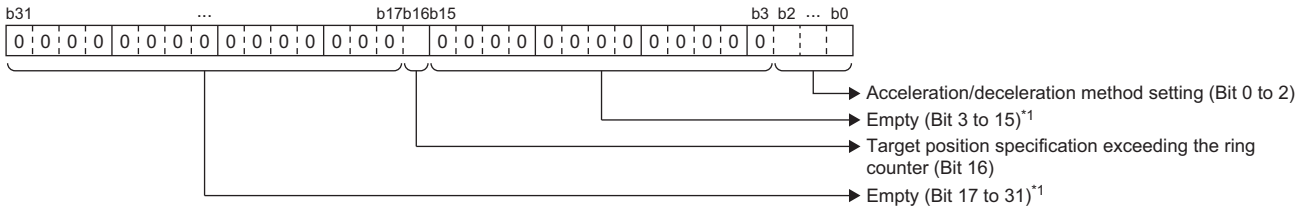
For details on the acceleration/deceleration method, refer to the following.

☞ Page 1078 Acceleration/Deceleration Processing Function

■Circular interpolation error tolerance (CircErrorTolerance)

Set the circular interpolation error tolerance when executing the circular interpolation control of center point specification.

The setting details differ depending on the settings of the Control method (ControlMethod).



For details on the circular interpolation error tolerance (CircErrorTolerance), refer to the following.

☞ Page 660 Circular interpolation error tolerance

The setting range is "0.000001 to 100000.0".

■Positioning data options (DataOptions)

Set the function options of linear interpolation control and circular interpolation control by bit specification.

*1 Set "0" to the empty space. When setting other than "0", Out of options range (error code: 1ABBH) occurs.

Bit	Name	Description
0 to 2	Acceleration/deceleration method setting	Sets the acceleration/deceleration method to execute control. • 0: Acceleration/deceleration specification method (mcAccDec) • 1: Acceleration/deceleration time-fixed method (mcFixedTime) * For details on the acceleration/deceleration method, refer to the following. ☞ Page 1078 Acceleration/deceleration method
16	Target position specification exceeding the ring counter	Sets whether the target position that exceeds the ring counter upper limit value and the ring counter lower limit value is allowed or not when the software stroke limit is disabled. Sets when "0101H: Absolute value linear interpolation (LinearAbsolute)" is set in Control method (ControlMethod). • 0: Not allowed • 1: Allow

■Dwell time (DwellTime)

Set the dwell time.

The setting range is shown below.

• 0.0 [s]: Dwell function disabled

• 0.000001 [s] to 8400.0 [s]: Dwell function enabled

*1 When a positive number less than 0.000001 is set, the value is imported as "0.0 [s]".

■M code (Mcode)

Set the M code for each positioning data.

Set "0 (initial value)" when the M code is not output.

The setting range is "1 to 65535".

■M code output timing override (McodeOutput_Override)

Set the M code output timing for each positioning data.

For details on the M code output timing, refer to the following.

☞ Page 700 M code output function

Setting value	Description
0: Use FB options (UseFbOptions)	Use the setting value of M code output timing (Options (Options): bit 16) for MCv_MovePositioningData (multiple axes positioning data operation).
1: WITH mode (WithMode)	At the start of positioning of the positioning data, the M strobe (Mstrobe) is set to TRUE, and the M code (Mcode) of the positioning data is stored in a valid M code (ValidMcode).
2: AFTER mode (AfterMode)	At the time of reaching the target position (after the set time elapses if dwell time is set), the M strobe (Mstrobe) is set to TRUE, and the M code of the positioning data is stored in the M code (Mcode).

■Jump destination positioning data No. (JumpDestinationDataNo)

Set the positioning data No. of the jump destination in JUMP.

Set the positioning data No. (DataNo) for the positioning data whose Control method (ControlMethod) is other than "0082H: JUMP (JUMP)".

The setting range is "1 to total number of positioning data".

■Condition signal No. (ConditionSignalNo)

Set the condition signal No.

Set "0 (initial value)" when the condition signal is not used.

The setting range is "1 to 10".

■Number of LOOP to LEND repetitions (LoopCount)

Set the number of repetitions of loop control.

The setting range is "1 to 65535".

■Skip signal No. (SkipSignalNo)

Set the skip signal No.

■Pitch (Pitch)

Set "0".

Pre-read

In MCv_MovePositioningData (multiple axes positioning data operation), the motion system pre-reads positioning data ahead from the positioning data that is being executed from the open area of the operation profile data and imports it.

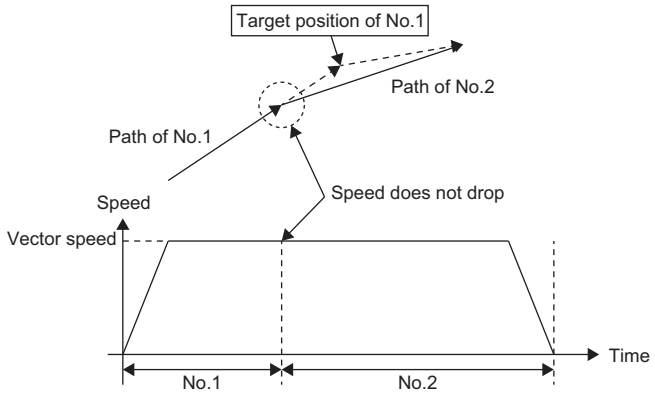
- When executing FB, the multiple axes interpolation data up to 4 ahead from the start positioning data No. (StartDataNo) is pre-read. When executing FB, if the positioning continues even after the pre-read multiple axes interpolation data, the pre-reading is executed while the FB is executed. The pre-reading is executed when the positioning data is switched so that the multiple axes interpolation data up to 4 ahead from the positioning data that is being executed is pre-read.
- The end positioning data No. of the pre-read multiple axes interpolation data is stored in the pre-read positioning data No. (PrereadingDataNo) during FB execution.

Precautions

If the positioning data with a short movement amount is executed continuously, the positioning data in the middle may be waiting for pre-reading.

When waiting for pre-reading in the continuous path data, the set velocity is rapidly changed to "0" in one operation cycle when the target position is reached. After that, the pre-reading is executed and if the data is switched to the positioning data one ahead, the set velocity is rapidly changed to a switching velocity in one operation cycle.

To avoid rapid changes in velocity due to the pre-reading waiting, increase the movement amount of each positioning data or reduce the target velocity.



Near pass

For continuous path data, the operation of near pass is executed to suppress machine vibration which occurs at switching of the positioning data of one ahead.

Near pass passes the remainder of the movement amount which occurs at the end of the positioning to the positioning of one ahead. As the alignment is not carried out for each positioning, drops in command velocity can be eliminated and machine vibration which occurs by the velocity change can be suppressed. Since the alignment is not executed for each positioning, the operation is controlled in a path that passes near the target position of the positioning data.

Ex.

When the 2-axis linear interpolation is executed with continuous path (operation pattern of No.1 set as continuous path and continued to No.2)

Precautions

When executing multiple axes interpolation operation with continuous path data, if the movement mount of the multiple axes interpolation operation is small, the command velocity may not reach the target velocity.

Combination with other functions

This section describe the content when the positioning data is executed in the operation pattern for positioning continue.

■Software stroke limit

Basic operation is based on the software stroke limit specifications for the motion FB. For details, refer to the following.

☞ Page 1061 Software Stroke Limit

- Returning from outside the software stroke limit range: While the software stroke limit is disabled in Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit_Override) for the axes group configuration axis, Start when SW stroke limit is disabled (event code: 07F5H) is recorded in the event history even when positioning data is pre-read in addition to the case of start or multiple start.
- Checking the software stroke limit enabled/disabled
  - By the Software Stroke Limit Override (AxisName.Md.SwStrokeLimit_Override) of each axes group configuration axis, the software stroke limit check enabled/disabled status can be checked.
  - In addition to start or multiple start, when the positioning data is pre-read, the Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit_Override) of the axes group configuration axis is imported and the Software Stroke Limit Override (AxisName.Md.SwStrokeLimit_Override) is updated. For details on the import value and updating value, refer to the following.

  ☞ Page 1067 Checking the software stroke limit enabled/disabled
- Software stroke limit check specifications: For MCv_MovePositioningData (multiple axes positioning data operation), the check is added for each positioning data.

Check timing	Check details	Processing when an error occurs
When executing FB or during control (When pre-reading positioning data)	An error shall occur if the target position of the positioning data is outside the software stroke limit range.	Software Stroke Limit Over (Target Position) (error code: 1A80H) occurs and the axis control is not executed.
	An error shall occur if the position at the time of executing the positioning data is outside the software stroke limit range.	Software Stroke Limit Over (Start Position) (error code: 1A81H) occurs and the axis control is not executed.
During control	An error shall occur if the current position is outside the software stroke limit range in the middle of control.	Software Stroke Limit Over (Forward Direction) (error code: 1A83H) or Software Stroke Limit Over (Reverse Direction) (error code: 1A84H) occurs and the stop processing is executed.*1

*1 The error occurs when a command to a position outside the software stroke limit range is detected, and the stop processing is executed. To stop within the software stroke limit range, set to "Immediate Stop".

■Hardware stroke limit check

Basic operation is based on the hardware stroke limit specifications for the motion FB. For details, refer to the following.

☞ Page 1069 Hardware Stroke Limit

- Returning from outside the hardware stroke limit range: While the hardware stroke limit is disabled in Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit_Override) for the axes group configuration axis, Start when HW stroke limit is disabled (event code: 07F6H) is recorded in the event history even when positioning data is pre-read in addition to the case of start or multiple start.
- Checking the hardware stroke limit enabled/disabled
  - By the Hardware Stroke Limit Override (AxisName.Md.HwStrokeLimit_Override) of each axes group configuration axis, the hardware stroke limit check enabled/disabled status can be checked.
  - In addition to start or multiple start, when the positioning data is pre-read, the Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit_Override) of the axes group configuration axis is imported and the Hardware Stroke Limit Override (AxisName.Md.HwStrokeLimit_Override) is updated. For details on the import value and updating value, refer to the following.

  ☞ Page 1075 Checking whether the hardware stroke limit is enabled/disabled

■Positioning speed

Basic operation is based on the positioning speed specifications in multiple axes positioning control. For details, refer to the following.

☞ Page 638 Positioning speed in multiple axes positioning control

- Operation when specifying velocity 0
  - If the Velocity (Velocity) of the positioning data to be positioned first is set to "0.0" and the MCv_MovePositioningData (multiple axes positioning data operation) is started, Out of velocity range (error code: 1ABAH) will occur. Use the override function when starting the positioning with a target velocity of "0.0" and executing the velocity change during control. For details on the override function, refer to the following.

  ☞ Page 1116 Override Function

  - For details on the override function in multiple axes positioning data operation, refer to the following.

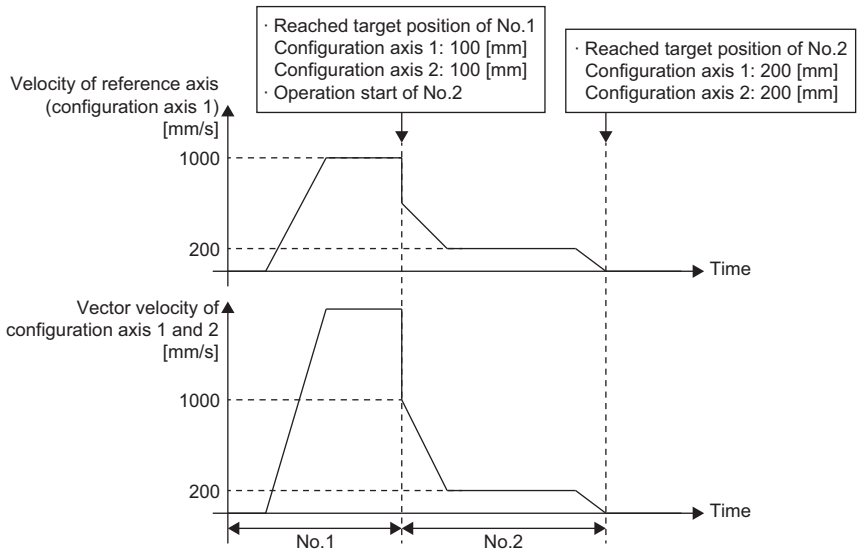
  ☞ Page 690 Override function

  - If the Velocity (Velocity) of the positioning data to be positioned first is set to "0.0" and the multiple start is executed for MCv_MovePositioningData (multiple axes positioning data operation), the following is the operation according to the commanded velocity of the previous FB.
    - 0.0: Out of velocity range (error code: 1ABAH) will occur when multiple start is executed.
    - Other than 0.0: Take over and use the commanded velocity of the previous FB.
  - If the Velocity (Velocity) of the positioning data in the middle is set to "0.0", the commanded velocity of the previous positioning data is taken over and used.
- During continuous path: This section describes the operation when selecting "2: Continuous path (BlendingLow) (ContinuousBlendingLow)", "3: Continuous path (BlendingPrevious) (ContinuousBlendingPrevious)", "4: Continuous path (BlendingNext) (ContinuousBlendingNext)", and "5: Continuous path (BlendingHigh) (ContinuousBlendingHigh)" in the operation pattern (OperationPattern) of the first positioning data (No.1), and setting a different velocity mode to the Velocity mode (VelocityMode) of the first positioning data (No.1) and the second positioning data (No.2) in the multiple axes positioning data operation.
  - The positioning continue for positioning data (No.1) and positioning data (No.2) can be executed even if the Velocity mode (VelocityMode) of the positioning data (No.1) and positioning data (No.2) is different. However, Multiple start velocity mode specified mismatch warning (event code: 0D11H) occurs when positioning data (No.2) is pre-read.
  - Positioning data (No.1) uses the Velocity mode (VelocityMode) of the positioning data (No.1) to execute positioning operations and positioning data (No.2) uses the Velocity mode (VelocityMode)of the positioning data (No.2) to execute positioning operations.
  - When switching the positioning data between positioning data (No.1) and positioning data (No.2), the velocity is not converted by the velocity mode. The positioning speed value observed in the velocity mode of the positioning data (No.1) is switched to the positioning speed observed in the velocity mode of the positioning data (No.2).
  - Note that the velocity of each axis and the vector velocity may rapidly change when switching the positioning data if the Velocity mode (VelocityMode) between positioning data (No.1) and positioning data (No.2) is different.

Ex.

For "3: Continuous path (BlendingPrevious) (ContinuousBlendingPrevious)"

The positioning data switching from the reference axis velocity specification to the vector velocity specification is as shown below.



It operates so that the No.1 reference axis velocity becomes the value of the velocity (reference axis velocity) set in Velocity (Velocity) of No.1 at the No.1 target position. The reference axis velocity when reaching the No.1 target position is read as the current vector velocity value of No.2 without unit conversion, and it accelerates/decelerates the vector velocity set to Velocity (Velocity) of No.2.

• Axis setting, Axes group setting

Setting item	Setting value
Position/Velocity command unit of configuration axis 1	mm/s
Position/Velocity command unit of configuration axis 2	mm/s
Position/Velocity command unit of the axes group	mm/s

• Setting of No.1 (command unit: mm/s) and No.2 (command unit: mm/s)

Setting item	Setting value	
	No.1	No.2
Operation pattern (OperationPattern)	3: Continuous path (BlendingPrevious) (ContinuousBlendingPrevious)	1: Continuous positioning (ContinuousPositioning)
Control method (ControlMethod)	0101H: Absolute value linear interpolation (LinearAbsolute)	0101H: Absolute value linear interpolation (LinearAbsolute)
Interpolation axis 1 (InterpolationAxis1)	1	1
Interpolation axis 2 (InterpolationAxis2)	2	2
Interpolation axis 3 (InterpolationAxis3)	0	0
Target position/Movement amount/End point 1 (Position1)	100	200
Target position/Movement amount/End point 2 (Position2)	100	200
Velocity mode (VelocityMode)	2: Reference Axis Velocity (ReferenceAxisSpeed)	0: Vector Velocity (VectorSpeed)
Velocity (Velocity)	1000	200

■Operation example

(1) Reaches the target position of No.1 at a reference axis velocity of 1000 [mm/s] of configuration axis 1 that is the reference axis, and switches to No.2.

(2) No.2 starts operation at a vector velocity of 1000 [mm/s].

(3) Decelerates to a vector velocity of 200 [mm/s].

(4) Performs positioning to the target position of No.2.

■Command unit

Basic operation is based on the command unit specifications during multiple axes positioning control. For details, refer to the following.

☞ Page 645 Command unit in the multiple axes positioning control

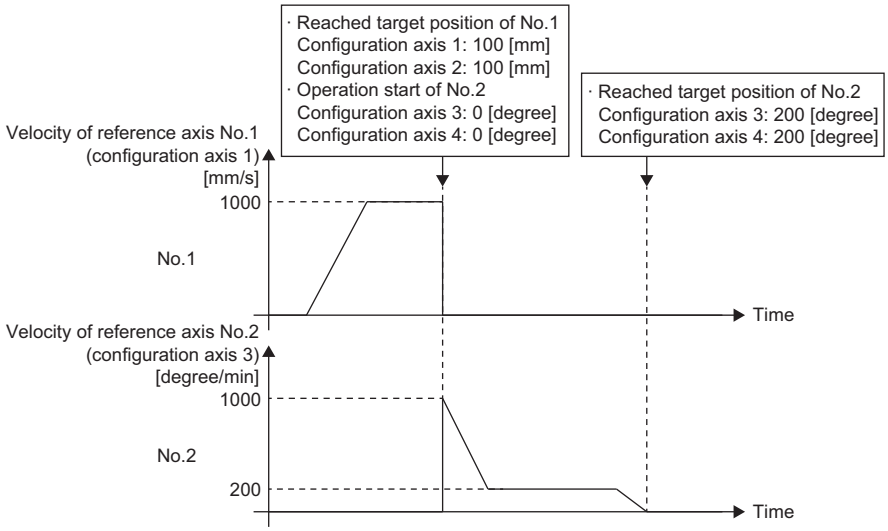
- Position command unit: When the combination of the position command unit between the axes group and the interpolation axes set in the positioning data is different, Position command unit mismatch warning (event code: 0D08H) occurs at start or pre-reading.
- Velocity command unit during continuous path: This section describes the operation when selecting "2: Continuous path (BlendingLow) (ContinuousBlendingLow)", "3: Continuous path (BlendingPrevious) (ContinuousBlendingPrevious)", "4: Continuous path (BlendingNext) (ContinuousBlendingNext)", and "5: Continuous path (BlendingHigh) (ContinuousBlendingHigh)" in the operation pattern (OperationPattern) of the first positioning data (No.1), and the velocity command unit of the first positioning data (No.1) and the second positioning data (No.2) is different in the multiple axes positioning data operation.
  - The positioning continue for positioning data (No.1) and positioning data (No.2) can be executed even if the command unit of the positioning data (No.1) and positioning data (No.2) is different. However, Position command unit mismatch warning (event code: 0D08H) occurs when positioning data (No.2) is pre-read.
  - Positioning data (No.1) uses the command unit of the positioning data (No.1) to execute positioning operations and positioning data (No.2) uses the command unit of the positioning data (No.2) to execute positioning operations.
  - When switching the positioning data between positioning data (No.1) and positioning data (No.2), the velocity is not converted by the command unit mode. The positioning speed value observed in the command unit of the positioning data (No.1) is switched to the positioning speed observed in the command unit of the positioning data (No.2).

Ex.

For "3: Continuous path (BlendingPrevious) (ContinuousBlendingPrevious)"

Even if the command unit of No.1 and No.2 is different, the operation pattern of No.1 can be set as continuous path to continue positioning with No.2. Unit conversion is not carried out, and the speed value of No.1 is given as the speed of No.2.

- Axis setting



Setting item	Setting value
Position/Velocity command unit of configuration axis 1	mm/s
Position/Velocity command unit of configuration axis 2	mm/s
Position/Velocity command unit of configuration axis 3	degree/min
Position/Velocity command unit of configuration axis 4	degree/min

• Setting of No.1 and No.2

Setting item	Setting value	
	No.1*1	No.2*2
Operation pattern (OperationPattern)	3: Continuous path (BlendingPrevious) (ContinuousBlendingPrevious)	1: Continuous positioning (ContinuousPositioning)
Control method (ControlMethod)	0101H: Absolute value linear interpolation (LinearAbsolute)	0101H: Absolute value linear interpolation (LinearAbsolute)
Interpolation axis 1 (InterpolationAxis1)	1	3
Interpolation axis 2 (InterpolationAxis2)	2	4
Interpolation axis 3 (InterpolationAxis3)	0	0
Target position/Movement amount/End point 1 (Position1)	100	200
Target position/Movement amount/End point 2 (Position2)	100	200
Velocity mode (VelocityMode)	2: Reference Axis Velocity (ReferenceAxisSpeed)	2: Reference Axis Velocity (ReferenceAxisSpeed)
Velocity (Velocity)	1000	200

*1 The command unit of No.1 will be changed to "mm/s" as it is the command unit of configuration axis 1.

*2 The command unit of No.2 will be changed to "degree/min" as it is the command unit of configuration axis 3.

■Operation example

(1) Reaches the target position of No.1 at a reference axis velocity of 1000 [mm/s] of configuration axis 1 that is the reference axis, and switches to No.2.

(2) No.2 starts operation at a reference axis (configuration axis 3) velocity of 1000 [degrees/min].

(3) Decelerates to a reference axis (configuration axis 3) velocity of 200 [degrees/min].

(4) Performs positioning to the target position of No.2.

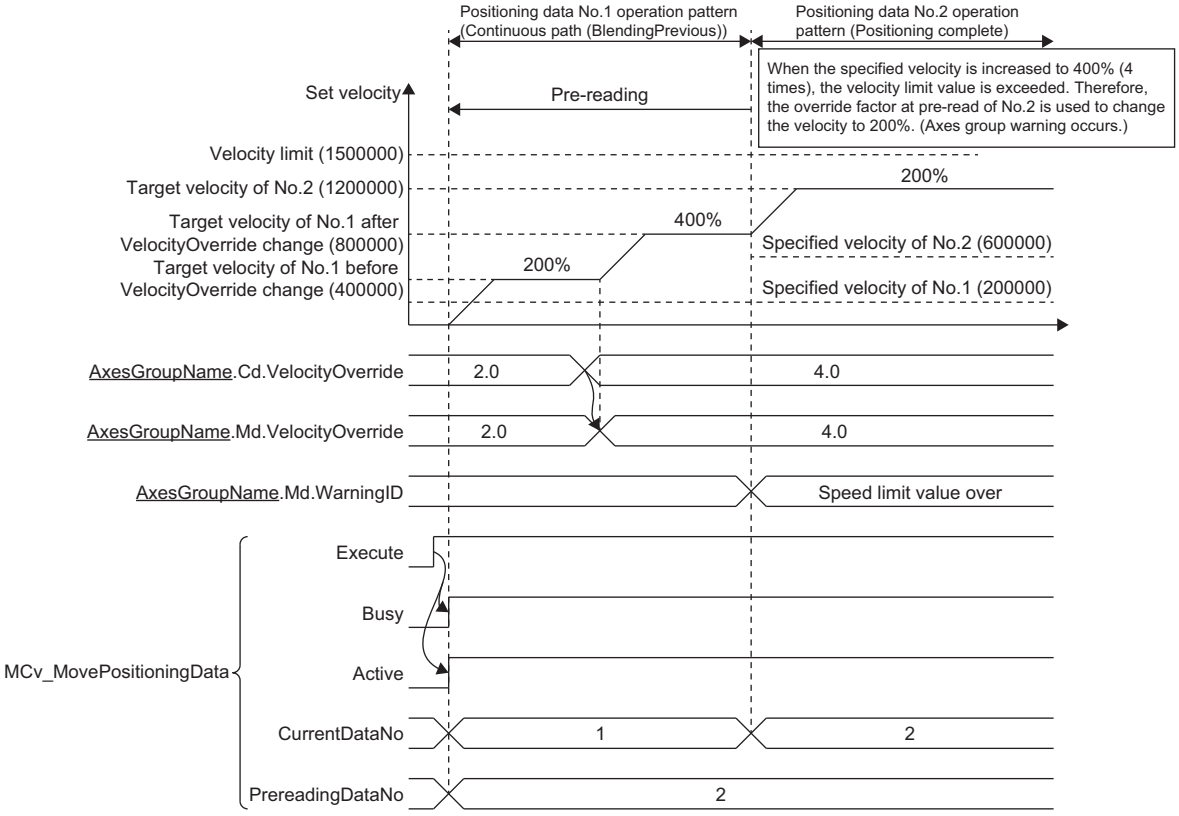
■Velocity limit

Basic operation is based on the velocity limit specifications during interpolation control. For details, refer to the following.

☞ Page 1112 Velocity Limit

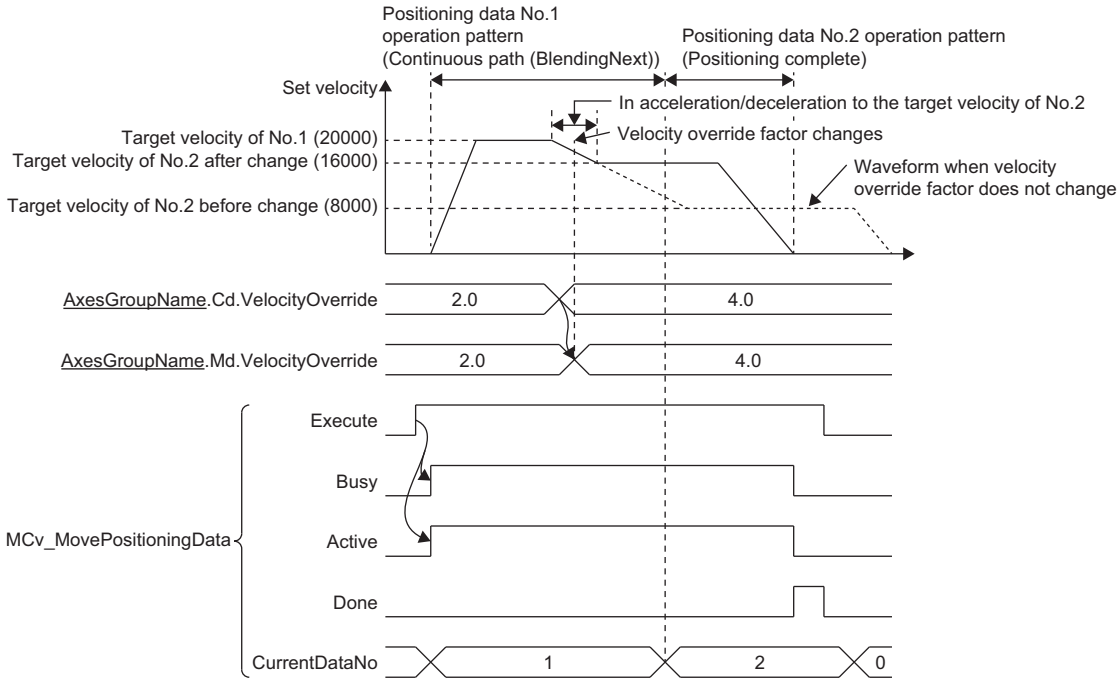
Execute the velocity limit for each positioning data.

If the target velocity of the positioning data in the middle exceeds the velocity limit, the operation will be the same as when starting.



Velocity limit value over (error code: 1A87H) is output at the time of startup or pre-reading during control.

■Override function



Basic operation is based on the override function specifications. For details, refer to the following.

☞ Page 1116 Override Function

- Operation when velocity/acceleration/deceleration limit value over occurs by override: The operation when velocity/acceleration/deceleration limit value over occurs at positioning data switching is shown below.
  - The control change of the next positioning data is executed at switching.
  - When the control is changed at switching, velocity/acceleration/deceleration limit value over may occur. When velocity/acceleration/deceleration limit value over occurs, the override factor at pre-reading is used to control.
  - Also when velocity/acceleration/deceleration limit value over occurs at switching, the import of override factor is executed. If the limit value is not exceeded at the next control change, the override factor after change will be used for operation.

• Target velocity change during acceleration/deceleration with "4: Continuous path (BlendingNext) (ContinuousBlendingNext)": The operation when the target velocity is changed during acceleration/deceleration until the next positioning target velocity while the positioning data whose operation pattern is "4: Continuous path (BlendingNext) (ContinuousBlendingNext)" is being executed is shown below.

Condition signal setting

This section describes the setting items for Condition signal 1 to Condition signal 10 (ConditionSignal1 to ConditionSignal10) when used in multiple axes positioning data operation.

• The condition signal is used to set the JUMP execution condition to the positioning data whose Control method (ControlMethod) is "0082H: JUMP (JUMP)". For details, refer to the following.

☞ Page 672 Control method (ControlMethod)

• The setting ranges and descriptions for each item are shown below.

Setting item	Setting range	Description
I/O number (StartIO)	—	Not used. The setting is disabled.
Target (Target)	• ""*1 ■Data type • [OBJ]*2*3 • [VAR] • [DEV] ■Type • BOOL * For details on the string format to be set, refer to the following. ☞ Page 1158 TARGET_REF Structure	Sets the signal to be used. ■Setting examples [VAR]AxisName.Md.InVelocity [OBJ] (WORD) 0x60FD0020.0@192.168.4.1
Signal detection method (Detection)	• 0: Detection at TRUE (HighLevel) • 1: Detection at FALSE (LowLevel)	Sets the signal logic.
Compensation Time (CompensationTime)	0.0	Set to "0.0".
Filter Time (FilterTime)	0.0	Set to "0.0".

*1 If the target (Target) is "" (string that has a length of 0), the corresponding condition signal is considered as no setting.

*2 If [OBJ] is set, the target modification cannot be omitted. If the setting is complete with the target modification omitted, Condition signal setting incorrect (error code: 1B37H) will occur.

*3 The MELSEC MX Controller supports specifying "[OBJ]". However, this data type cannot be set in the setting window of GX Works3 version 1.115V. Alternatively, create a network label corresponding to the object to be specified with "[OBJ]", and specify it as "[VAR]". (☞ Page 108 Network labels)

• If a value outside the range is set, Condition signal setting incorrect (error code: 1B37H) will occur when executing FB.

Skip signal setting

This section describes the setting items for Skip signal 1 to Skip signal 10 (SkipSignal1 to SkipSignal10) when used in multiple axes positioning data operation.

- The skip signal is set when the skip function is used. For details, refer to the following.

☞ Page 695 Skip function

- The setting ranges and descriptions for each item are shown below.

Setting item	Setting range	Description
I/O number (StartIO)	—	Not used. The setting is disabled.
Target (Target)	• ""*1 ■Data type • [OBJ]*2 • [VAR] • [DEV] ■Type • BOOL * For details on the string format to be set, refer to the following. ☞ Page 1158 TARGET_REF Structure	Sets the signal to be used. ■Setting examples [VAR]AxisName.Md.InVelocity [OBJ] (WORD) 0x60FD0020.0@192.168.4.1
Signal detection method (Detection)	• 0: Detection at TRUE (HighLevel) • 1: Detection at FALSE (LowLevel)	Sets the signal logic.
Compensation Time (CompensationTime)	0.0	Set to "0.0".
Filter Time (FilterTime)	0.0 to 5.0 [s]	Sets the filter time for removing chattering of the I/O signals in units of seconds.

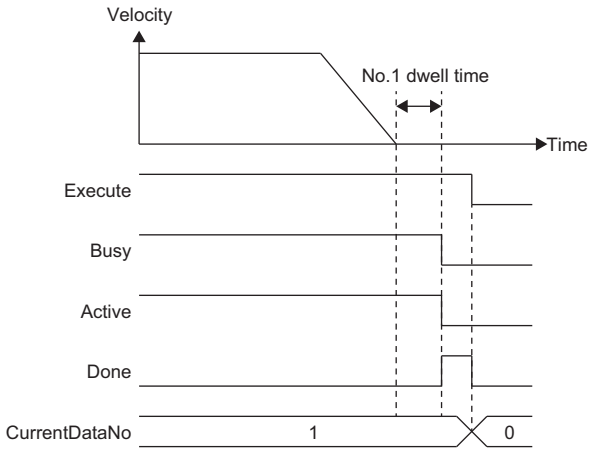
*1 If the target (Target) is "" (string that has a length of 0), the corresponding skip signal is considered as no setting.

*2 If [OBJ] is set, the target modification cannot be omitted. If the setting is complete with the target modification omitted, Skip signal setting incorrect (error code: 1B38H) will occur.

- If a value outside the range is set, Skip signal setting incorrect (error code: 1B38H) will occur when executing FB.

Dwell function

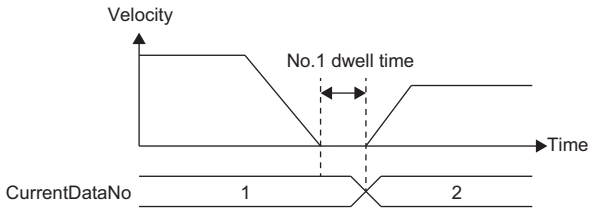
After stopping the positioning, wait for the elapsed time to complete the positioning data.



The dwell function is enabled when a value other than "0.0 [s]" is set to the dwell time.

The dwell time is set to the Dwell time (DwellTime) of the positioning data.

The following operations depend on the operation pattern.



■When the operation pattern is positioning complete

The positioning data operation is completed after the dwell time elapses after positioning is stopped.

■When the operation pattern is continuous positioning

Move to the positioning operation of the next positioning data after the dwell time elapses after positioning is stopped.

■When the operation pattern is continuous path

The operation is the same as the one when the operation pattern is "Continuous positioning".

Specify "0.0 [s] (Disabled)" for dwell time when the operation of continuous path is executed without waiting for dwell time to elapse.

Precautions

- Setting the dwell time at the control cycle interval (a value obtained by multiplying the control cycle by an integer) of the axes group configuration axis is recommended. If it is not a control cycle interval, wait for the elapsed time as shown in the table below, depending on the relationship with one control cycle.

Setting value of Dwell time (DwellTime)	Waiting for dwell time to elapse
Less than one control cycle	Waiting time is only for one control cycle.*1
One control cycle or more	Waiting time is only for the time with the fractional part truncated by the scale of the control cycle.

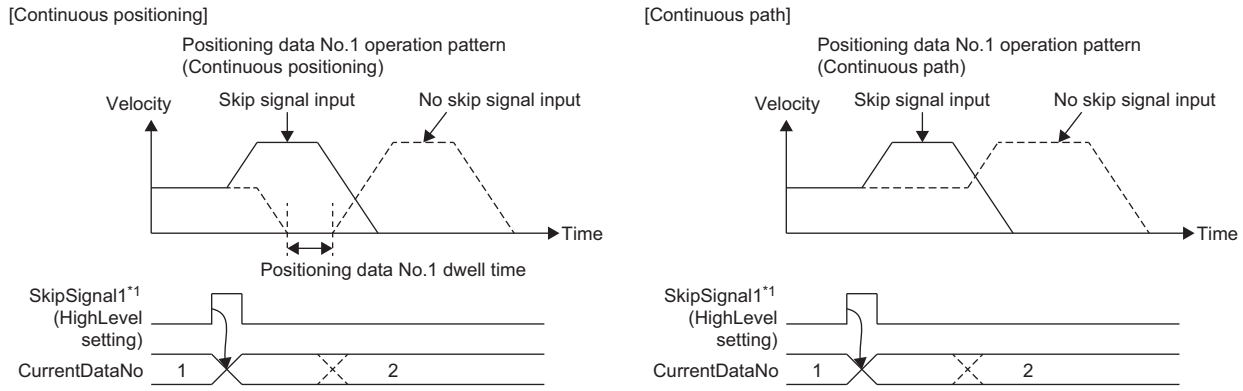
*1 Set the Dwell time (DwellTime) to "0.0 [s]" when disabling waiting for dwell time to elapse.

Ex.
For the following

Example	Description
1	■When the dwell time is less than one control cycle When the control cycle is set to "0.001 [s] (1.0 [ms])", if "0.0005 (0.5 [ms])" is set in the Dwell time (DwellTime), the waiting time for the dwell time to elapse is only for "0.001 (1.0 [ms])".
2	■When the dwell time exceeds one control cycle When the control cycle is set to "0.001 [s] (1.0 [ms])", if "0.0025 (2.5 [ms])" is set in the Dwell time (DwellTime), the waiting time for the dwell time to elapse is only for "0.002 (2.0 [ms])".

Skip function

By setting a skip signal for each positioning data, the operation of the positioning data that is being executed is interrupted and the next positioning data is executed.



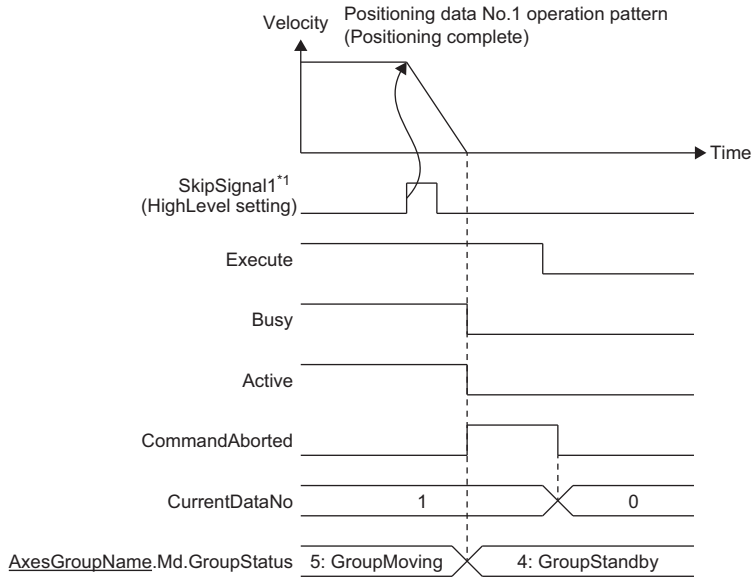
- The skip function uses the Skip signal 1 to Skip signal 10 (SkipSignal1 to SkipSignal10) of the operation profile data (multiple axes positioning data format). The external signal (bit input signal) is set to the skip signal. For details on the setting, refer to the following.

☞ Page 692 Skip signal setting

- The skip signal is imported by the control cycle of the configuration axis for the axes group to be controlled.
- The number used for each positioning data is set from the skip signal as the Skip signal No. (SkipSignalNo).
- When "0" is set to the Skip signal No. (SkipSignalNo) of the positioning data, the skip function is disabled during the execution of the corresponding positioning data.
- If the skip signal set by the Skip signal No. (SkipSignalNo) of the positioning data being executed is input, the skipping is executed.
- The following operations depend on the operation pattern.

■When the operation pattern is continuous positioning or continuous path

Move to the next positioning data after interrupting the operation of the positioning data that is being executed by inputting a skip signal.



*1 Skip signal No. (SkipSignalNo) "1" of positioning data No.1 and Skip signal No. (SkipSignalNo) "0" of No.2

■When the operation pattern is positioning complete

By inputting a skip signal, a deceleration stop is executed.

- The acceleration/deceleration method and deceleration of the deceleration stop, and the jerk, take over the value of the skipped positioning data. When the command velocity reaches 0, the execution of MCv_MovePositioningData (multiple axes positioning data operation) during control is interrupted (Abortion of execution (CommandAborted) is TRUE), and Axes Group Status (AxesGroupName.Md.GroupStatus) will transit to "4: Standby (GroupStandby)".

*1 Skip signal No. (SkipSignalNo) "1" of positioning data No.1

- When skipping, the next positioning data (multiple axes interpolation data) uses the position at the time of inputting the skip signal as the start position for positioning. The setting examples of the positioning position when skipping are shown below.

■Setting example

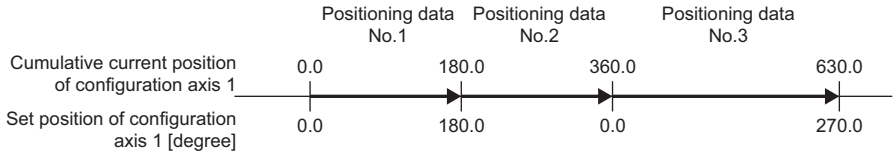
The axes group with axis 1 of ring counter enabled and software stroke limit disabled as the configuration axis is as shown below.

• Setting of axis specified by configuration axis 1 (AxesGroupName.Pr.Axis[1])

Setting item	Setting value
Ring Counter Enabled Selection (AxisName.PrConst.RingCount_Enable)	TRUE
Ring Counter Lower Limit Value (AxisName.PrConst.RingCount_LowerValue)	0.0
Ring Counter Upper Limit Value (AxisName.PrConst.RingCount_UpperValue)	360.0
Software Stroke Limit Target (AxisName.Pr.SwStrokeLimit_Target)	-1: Invalid (Invalid)
Position Command Unit (AxisName.Pr.Unit_Position)	H00410000 (degree)

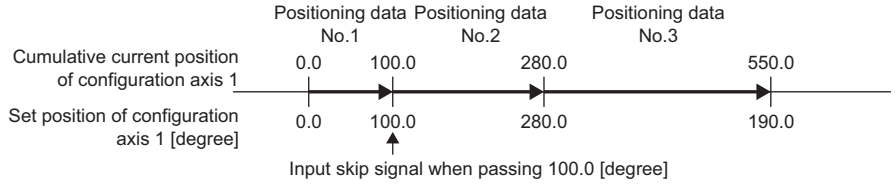
Under these conditions, if there is positioning data of absolute position specification after skipping, the set position at the time of execution completed (Done) rise is the same regardless of whether the skip signal is input or not. However, the cumulative current position (movement distance during operation) at the time of execution completion (Done) rise may be different. In addition, the movement direction may change by positioning data of absolute position specification depending on whether the skip signal is input or not.

■When all the positioning data after skipping is relative position specification



• Positioning data setting

—: No setting



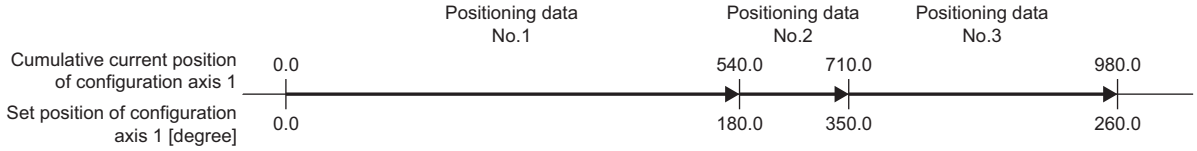
Positioning data No. (DataNo)	Operation pattern (OperationPattern)	Control method (ControlMethod)	Interpolation axis 1 (InterpolationAxis1)	Target position/ Movement amount/End point 1 (Position1)	Direction selection 1 (Direction1)	Skip signal No. (SkipSignalNo)
1	3: Continuous path (BlendingPrevious) (ContinuousBlendingPrevious)	0102H: Relative value linear interpolation (LinearRelative)	1	180.0	—	1
2	3: Continuous path (BlendingPrevious) (ContinuousBlendingPrevious)	0102H: Relative value linear interpolation (LinearRelative)	1	180.0	—	—
3	0: Positioning complete (PositioningComplete)	0102H: Relative value linear interpolation (LinearRelative)	1	270.0	—	—

• Positioning operation

[When the skip signal is not input]

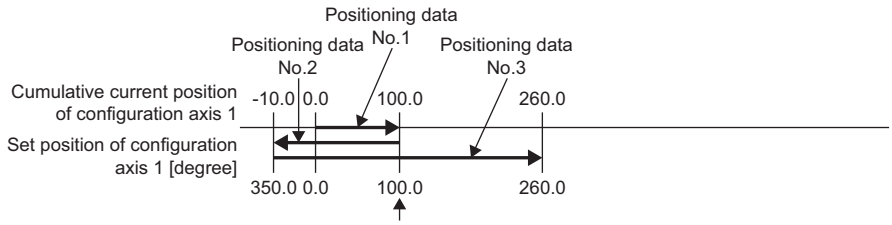
[When the skip signal is input]

■When the positioning data immediately after skipping is absolute position specification



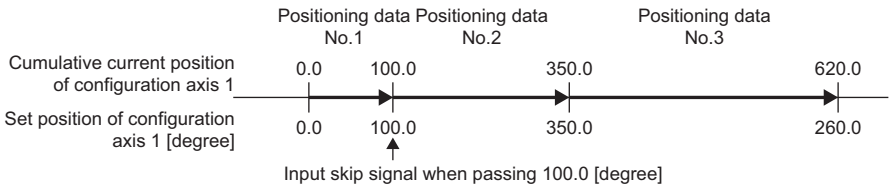
• Positioning data setting

—: No setting



Positioning data No. (DataNo)	Operation pattern (OperationPattern)	Control method (ControlMethod)	Interpolation axis 1 (InterpolationAxis1)	Target position/ Movement amount/End point 1 (Position1)	Direction selection 1 (Direction1)	Skip signal No. (SkipSignalNo)
1	3: Continuous path (BlendingPrevious) (ContinuousBlendingPrevious)	0102H: Relative value linear interpolation (LinearRelative)	1	540.0	—	1
2	3: Continuous path (BlendingPrevious) (ContinuousBlendingPrevious)	0101H: Absolute value linear interpolation (LinearAbsolute)	1	350.0	3: Shortest path (mcShortestWay)	—
3	0: Positioning complete (PositioningComplete)	0102H: Relative value linear interpolation (LinearRelative)	1	270.0	—	—

• Positioning operation

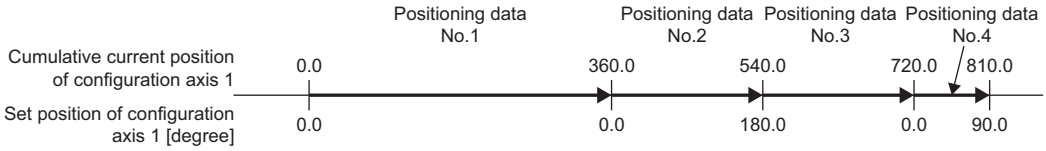


[When the skip signal is not input]

[When the skip signal is input]

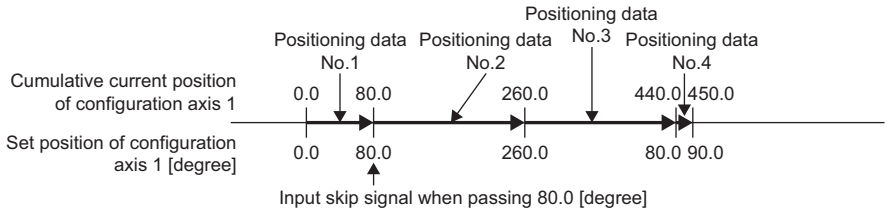
* In the above cases (the Direction selection 1 (Direction1) of positioning data No.2 is "3: Shortest path (mcShortestWay)"), the positioning is executed in the positive direction with positioning data No.2 even if the skip signal is input while positioning data No.1 is executed by setting the Direction selection 1 (Direction1) of positioning data No.2 to "1: Positive direction (mcPositiveDirection)".

■When the positioning data immediately after skipping is relative position specification, and there is absolute position specification after that



• Positioning data setting

—: No setting



Positioning data No. (DataNo)	Operation pattern (OperationPattern)	Control method (ControlMethod)	Interpolation axis 1 (InterpolationAxis1)	Target position/ Movement amount/End point 1 (Position1)	Direction selection 1 (Direction1)	Skip signal No. (SkipSignalNo)

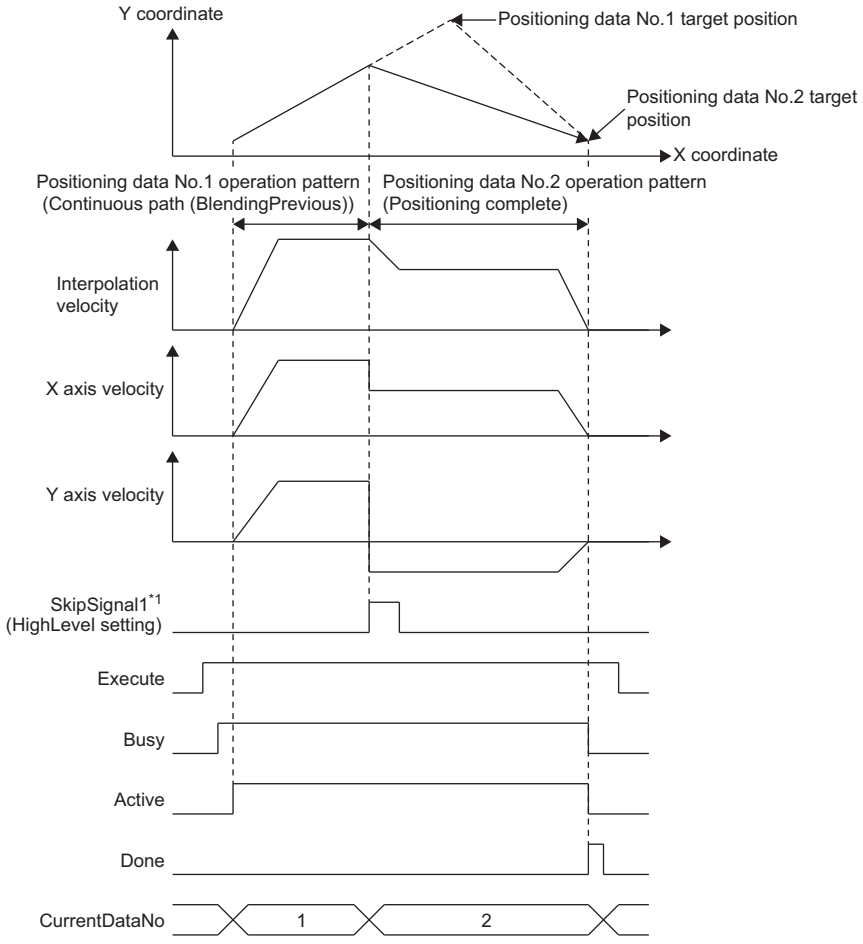
• Positioning operation

[When the skip signal is not input]

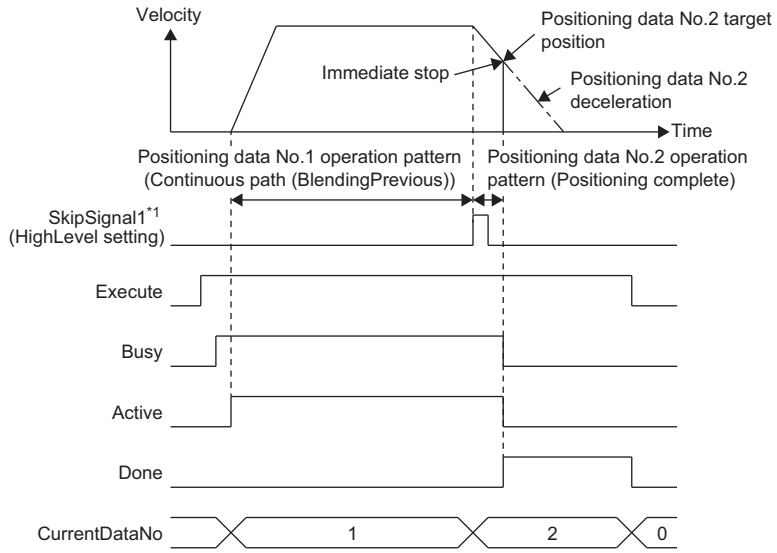


[When the skip signal is input]

Precautions

- The skip function interrupts positioning data being executed and does not omit pre-reading and execution even if a skip signal is input for the positioning data before execution. If the skip signal is set to the input status before the positioning data is executed, the skipping is executed when the positioning data is executed. Therefore, it takes one control cycle from the start of execution to the next positioning data switching.
- If the same skip signal is set and the positioning data to be executed is skipped continuously over several operation cycles, waiting for the pre-reading may occur. When waiting for the pre-reading due to skipping, the set velocity rapidly changes to 0 in one operation cycle at the time of inputting the skip signal. After that, the pre-reading is executed and if the data is switched to the next positioning data, the set velocity is rapidly changed to a switching velocity in one operation cycle. To avoid rapid changes in velocity due to waiting for the pre-reading, review the positioning data settings to avoid continuous skipping operations.

- If the Control method (ControlMethod) is set to "0103H: Absolute value circular interpolation (CircularAbsolute)" in the positioning data after the positioning data for which the skip signal is set, set the positioning data of "0101H: Absolute value linear interpolation (LinearAbsolute)" between them. Furthermore, configure the settings so that the interpolation axis of the positioning data of "0103H: Absolute value circular interpolation (CircularAbsolute)" is included in the interpolation axis of the positioning data of "0101H: Absolute value linear interpolation (LinearAbsolute)". Failure to do so will generate Incorrect control method after skipping (error code: 1B34H) after the skip signal is input and the operation will stop.
- If the Control method (ControlMethod) is set to "0101H: Absolute value linear interpolation (LinearAbsolute)" in the positioning data after the positioning data for which the skip signal is set, set the Velocity mode (VelocityMode) to the one other than "1: Long axis velocity (LongAxisSpeed)". If the positioning data whose Control method (ControlMethod) is set to "0101H: Absolute value linear interpolation (LinearAbsolute)" and Velocity mode (VelocityMode) is set to "1: Long axis velocity (LongAxisSpeed)" is pre-read when the skip signal is input, Incorrect control method after skipping (error code: 1B34H) will occur and the operation will stop.
- If skipping is executed while waiting for the dwell time to elapse, the waiting for elapse is ignored and the operation will be moved to the next positioning data.
- If skipping is executed during M code output (while M strobe (Mstrobe) is TRUE), M strobe (Mstrobe) will be FALSE and the M code reset will not be waited.
- For the positioning data for which M code output timing is "AFTER mode", when skipping is executed before the M code output, the operation is moved to the next positioning data without outputting the M code. (In this case, the M strobe (Mstrobe) does not rise during the execution of the corresponding positioning data, and the M code is not stored in the valid M code (ValidMcode).)
- When switching to the next positioning data by inputting the skip signal, the interpolation velocity at the time of switching is used as the switching velocity. Therefore, acceleration/deceleration may not be executed and a rapid velocity change may occur depending on the movement amount and movement direction of each axis for the next positioning data.



*1 Skip signal No. (SkipSignalNo) of positioning data No.1 is "1" and Skip signal No. (SkipSignalNo) of positioning data No.2 is "0"

- When switching to the next positioning complete data or continuous positioning data by inputting the skip signal, the deceleration distance cannot be secured after switching at the switching velocity, and the target position may be overrun. In this case, the automatic deceleration operation is executed based on Operation Setting at Overrun (AxesGroupName.Pr.OverrunOperation).

Ex.

When "1: Immediate Stop (ImmediateStop)" is set, the axis starts deceleration immediately as follows, and it stops immediately at reaching the target position after outputting overrun warning.

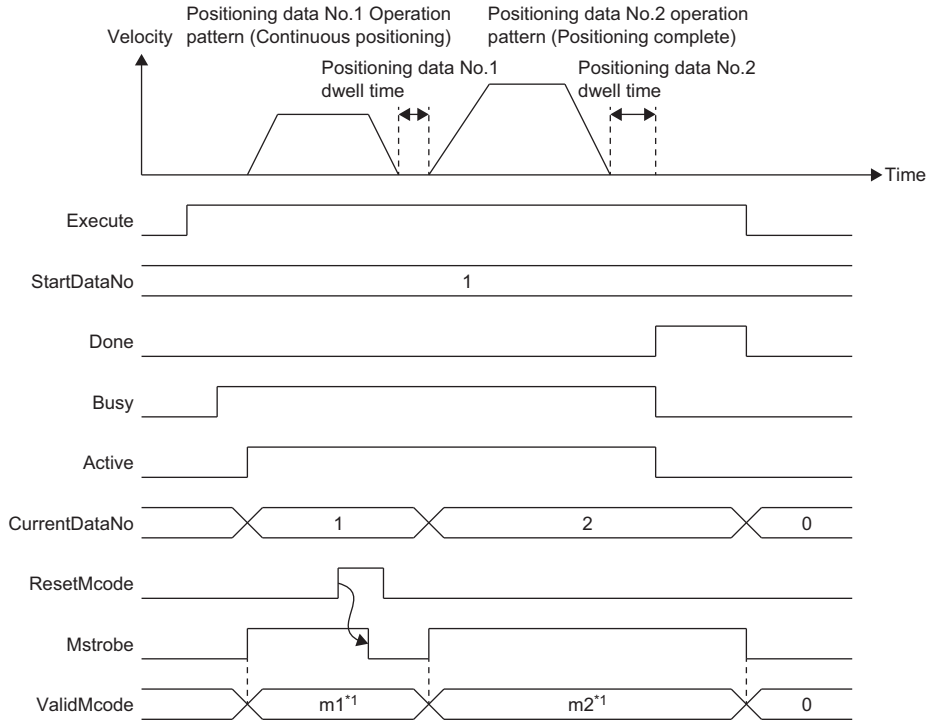
*1 Skip signal No. (SkipSignalNo) of positioning data No.1 is "1" and Skip signal No. (SkipSignalNo) of positioning data No.2 is "0"

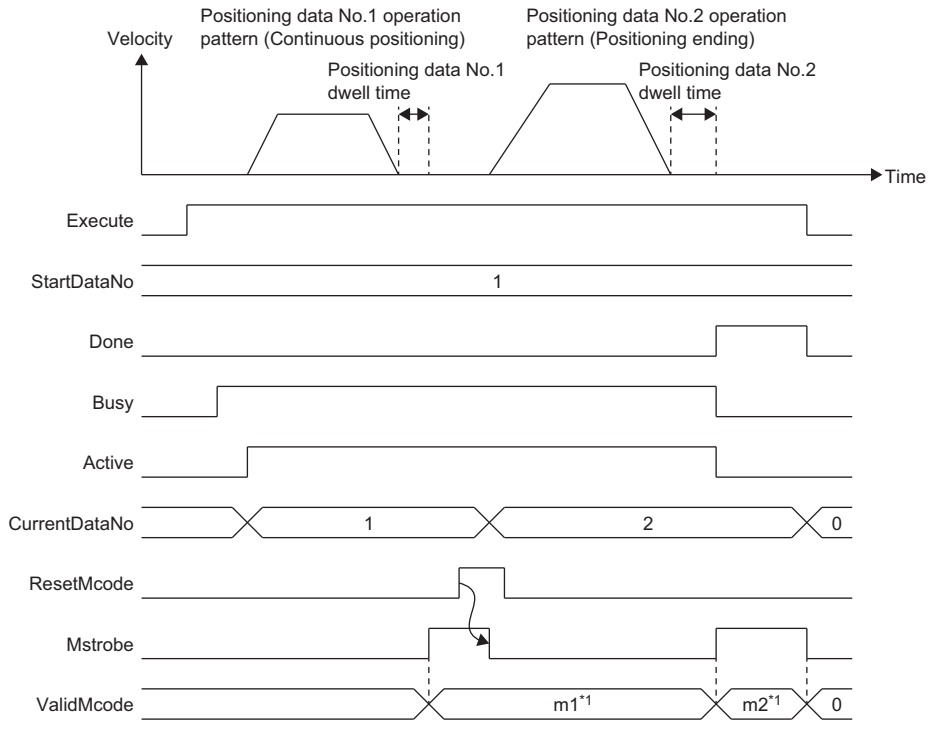
Point

When switching to continuous positioning data and decelerating due to insufficient movement amount, the positioning of the next positioning data No. is executed after stopping the axis.

- During the deceleration stop of the positioning complete data by inputting the skip signal, the change by the override function is not immediately reflected in the operation that is being executed. It is reflected at the timing when another stop cause occurs.
- If skipping is executed during acceleration/deceleration of continuous positioning data, acceleration (deceleration) is not taken over when switching positioning data even when switching "from the jerk acceleration/deceleration to another jerk acceleration/deceleration".
- If the refresh cycle of the signal set for the skip signal is different from the control cycle of the configuration axis for the axes group to be controlled, the signal may be lost. Maintain the signal status until CurrentDataNo is switched to the next positioning data No.

M code output function

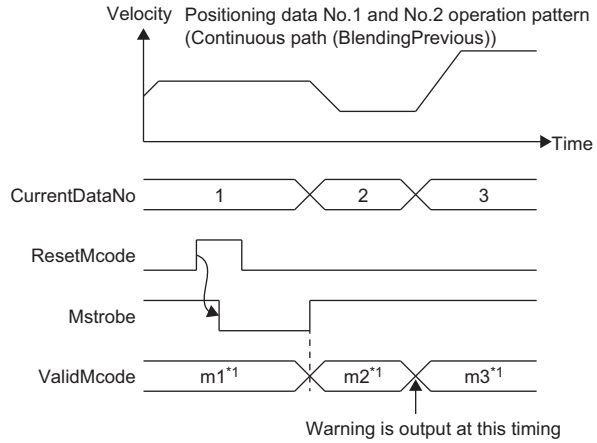


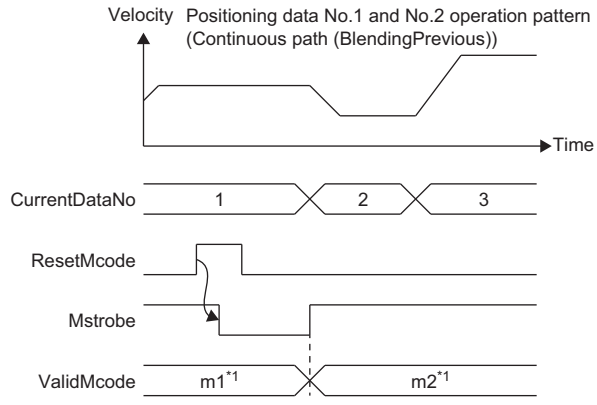


A function to execute the command of the auxiliary work (such as clamp, drill rotation, and tool replacement) related to positioning data that is being executed.

The M code can be set for each positioning data. The timing to output (store) the M code can also be set.

- This function is enabled when a value other than "0" is set to the M code.
- The M code is set to the M code (Mcode) of the positioning data.
- When executing each positioning data for multiple axes positioning data operation, the M strobe (Mstrobe) is set to TRUE at the set output timing, and the M code is stored in a valid M code (ValidMcode).

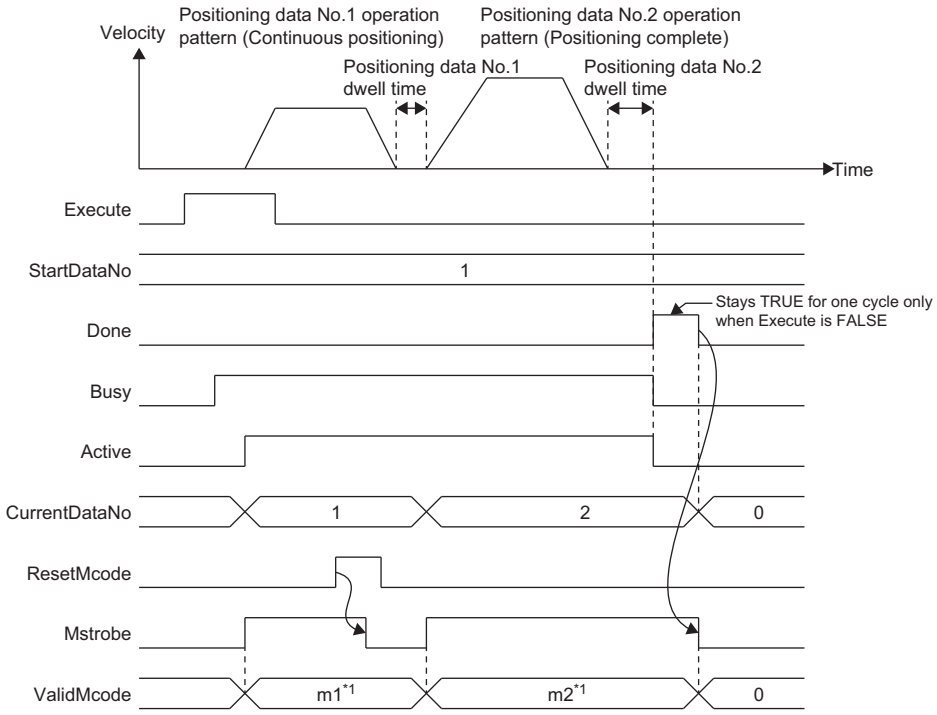




■M code output timing

- The M code output timing is set to the M code output timing (Options (Options): bit 16) for MCv_MovePositioningData (multiple axes positioning data operation). In addition, the M code output timing can be set for each positioning data by M code output timing override (McodeOutput_Override) of the positioning data.
- The timing for outputting the M code includes "WITH mode" and "AFTER mode".

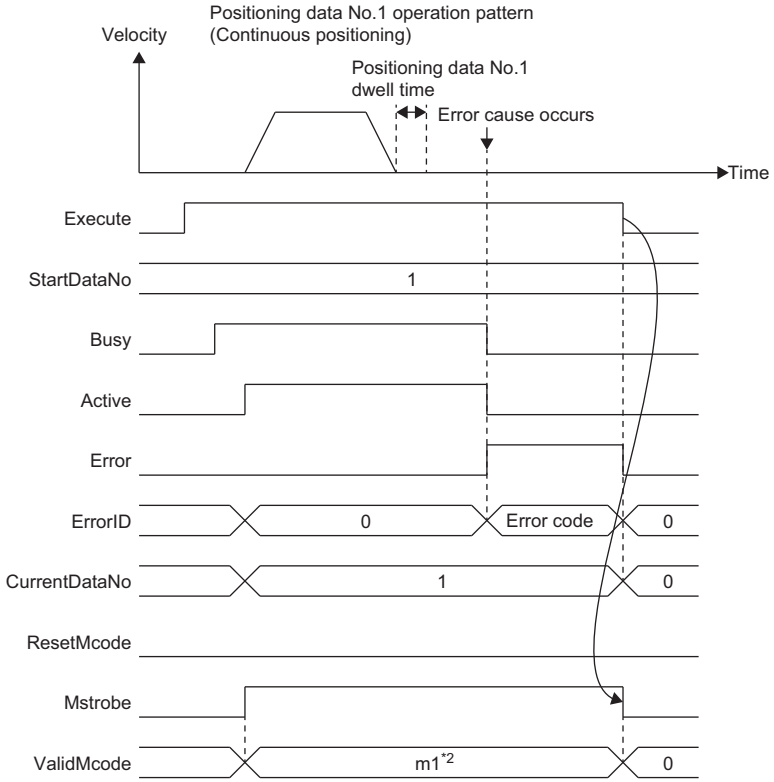
Output timing	Description
WITH mode	At the start of positioning of the positioning data, the M strobe (Mstrobe) is set to TRUE, and the M code (Mcode) of the positioning data is stored in a valid M code (ValidMcode).  *1 m1 and m2 indicate the M code (Mcode) set for each positioning data No.
AFTER mode	At the time of reaching the target position (after the set time elapses if dwell time is set), the M strobe (Mstrobe) is set to TRUE, and the M code of the positioning data is stored in the M code (Mcode).  *1 m1 and m2 indicate the M code (Mcode) set for each positioning data No.



■Function of waiting for M code reset

- During M code output (while M strobe (Mstrobe) is TRUE), wait for the processing of positioning data to be completed until M code reset is executed. The multiple axes positioning data operation is continued under control even during the wait state.
- M code reset is executed by starting the M code reset (ResetMcode). M strobe (Mstrobe) becomes FALSE due to M code reset.
- The following operations depend on the operation pattern.

Operation pattern	Description
Positioning complete	Do not wait for M code reset. Even if the M strobe (Mstrobe) is TRUE, FB is completed.
Continuous positioning	While M strobe (Mstrobe) is TRUE, wait to move to the next positioning data.
Continuous path	Do not wait for M code reset. Even if the M strobe (Mstrobe) is TRUE, the next positioning operation is executed. ■When the M code is set for the following positioning data Operation profile data control profile ID setting incorrect warning (event code: 0D48H) will occur.  *1 m1, m2, and m3 indicate the M code (Mcode) set for each positioning data No. ■When the M code is not set for the following positioning data No warning will be output, but M code output will continue.  *1 m1 and m2 indicate the M code (Mcode) set for each positioning data No. (M code (Mcode) of positioning data No.3 is "0 (no setting)")



Precautions

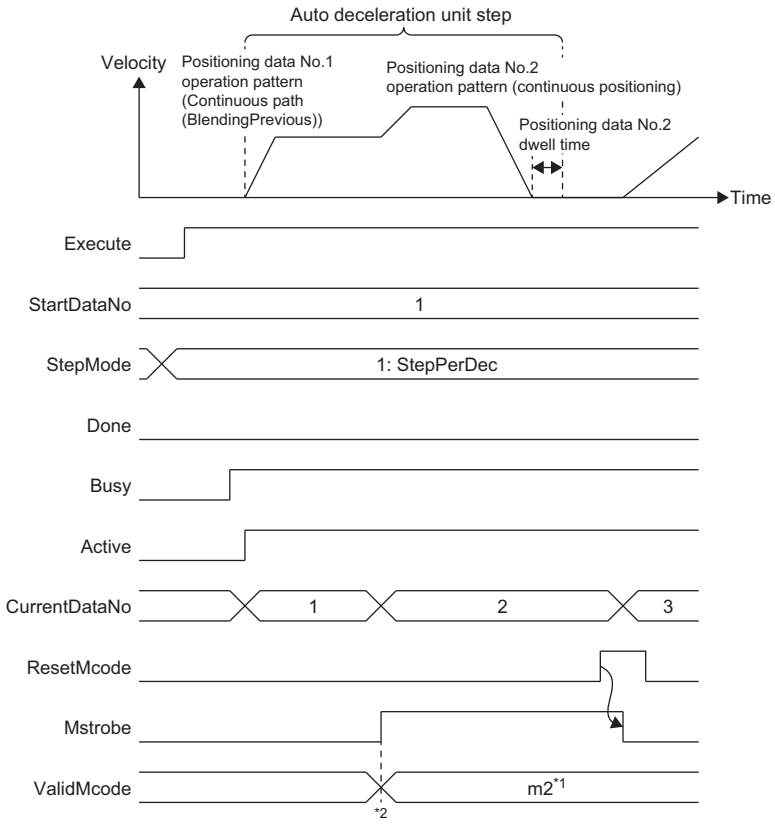
- If "0" is set for M code (Mcode), M code will not be output. (At M code output timing, M strobe (Mstrobe) is not TRUE and the valid M code (ValidMcode) is not updated.)
- M code reset is executed by starting the M code reset (ResetMcode). Even if the M code reset (ResetMcode) is set to TRUE in advance before the M strobe (Mstrobe) becomes TRUE, it will not be reset. To avoid starting an M code reset (ResetMcode) while the M strobe (Mstrobe) is FALSE, execute the mutual exclusion in the user program.
- For the continuous path, if the positioning operation time is short, the time to execute the M code reset may not be taken, and Operation profile data control profile ID setting incorrect warning (event code: 0D48H) may occur. In this case, the warning can be avoided without outputting the M code by setting "0" for the M code (Mcode) of the positioning data for the warning part.
- The valid M code (ValidMcode) and M strobe (Mstrobe) are reset upon completion if the execution command (Execute) is FALSE upon completion. They are reset when the execution command (Execute) is FALSE if the execution command (Execute) is TRUE upon completion.

*1 m1 and m2 indicate the M code (Mcode) set for each positioning data No.

• During the waiting for M code reset, if an error occurs or the execution is interrupted, the M strobe (Mstrobe) remains TRUE and the state of waiting for reset is released.

*2 m1 indicates the M code (Mcode) set for each positioning data No.

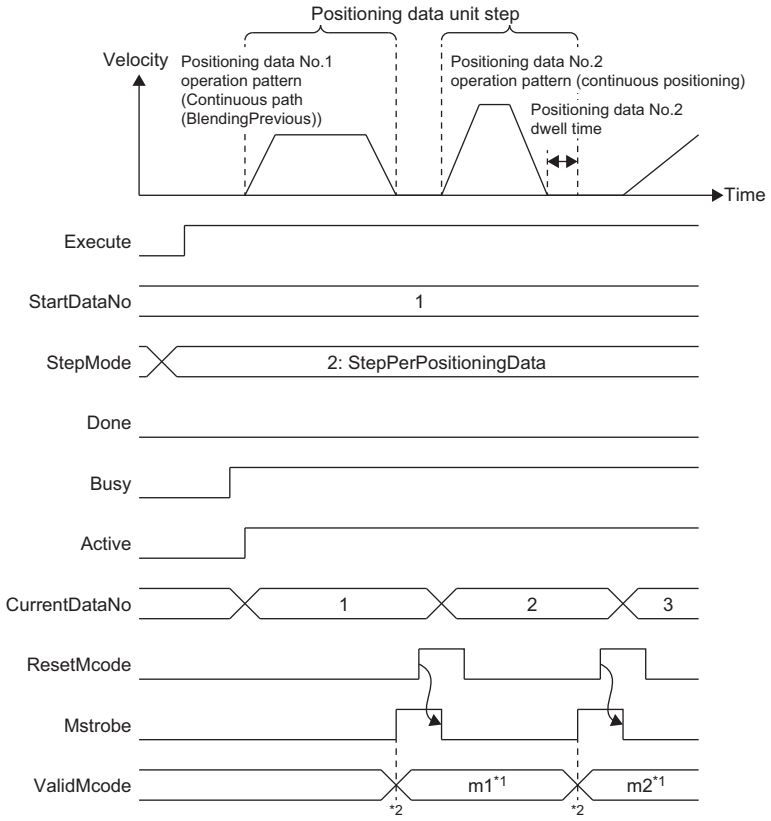
Step function



A function to check the positioning operation one by one. Use it for debugging work.
Multiple axes positioning data operation with "Step function" enabled is called "Step operation".
In step operation, the timing to pause the operation can be set. It is called "Step mode". (The multiple axes positioning data operation continues under control even during the pause.)

- To execute the step operation, set the Step mode (StepMode) to "1: Deceleration unit step (StepPerDec)" or "2: Positioning data unit step (StepPerPositioningData)" and execute MCv_MovePositioningData (multiple axes positioning data operation).
- In the positioning data to be paused in the step operation, execute the waiting for M code reset. In the positioning data whose M code output with "0" set in M code (Mcode) is invalid, M strobe (Mstrobe) becomes TRUE and waits for the M code reset. (The valid M code (ValidMcode) is not updated.)
- During M code output (while M strobe (Mstrobe) is TRUE), wait for the next step to continue.

■Step mode

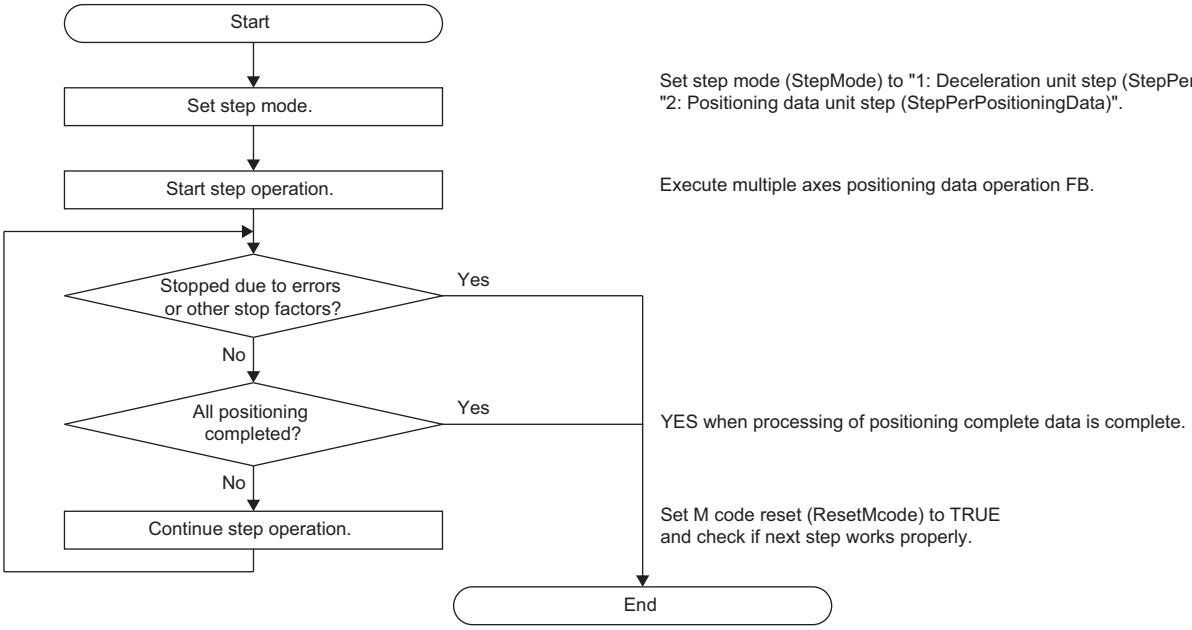


There are two types of "Step mode": "Deceleration unit step" and "Positioning data unit step".
In both modes, to release the pause and continue the next one step, set the M code reset (ResetMcode) to TRUE during M code output. In addition, as with normal operation, the multiple axes positioning data operation is completed after the processing of the positioning complete data is completed.

- "1: Deceleration unit step (StepPerDec)": Pause with continuous positioning data. Normal operation is executed for continuous path data and positioning complete data.

*1 m2 indicates the M code (Mcode) set for each positioning data No. (When M code (Mcode) is "0 (no setting)", it will not be updated.)
*2 When the M code output timing for each positioning data No. is "WITH mode"

• "2: Positioning data unit step (StepPerPositioningData)": Automatically decelerate and pause for each positioning data. Even for the continuous path data, it is forced to automatically decelerate and pause.



*1 m1 and m2 indicate the M code (Mcode) set for each positioning data No. (When M code (Mcode) is "0 (no setting)", it will not be updated.)

*2 When the M code output timing for each positioning data No. is "AFTER mode"

■How to use step operation

The procedure for checking the positioning data using step operation is shown below.

■Precautions

- As with normal operation, the skip function is also enabled in step operation. In the positioning data to be paused in the step operation, when skipping is executed before the pause, the next one step is continued without pausing. (During M code output, M strobe (Mstrobe) becomes FALSE.) In addition, if skipping is executed during the pause, the M strobe (Mstrobe) becomes FALSE, the pause is released and the next one step is continued.

Precautions

- In MCv_MovePositioningData (multiple axes positioning data operation), the operation profile data analysis such as pre-reading and external signal setting may extend the time required for start and multiple start (Aborting).
- If an error is detected during the control of multiple axes positioning data operation, MCv_MovePositioningData instruction error (error code: 1BD1H) is output along with the error indicating the error definition. Detailed information such as detected positioning data No. is recorded in the event history as the information of MCv_MovePositioningData instruction error (error code: 1BD1H).
- The timing of importing from the open area of operation profile data (multiple axes positioning data format) is different for each item. The following table lists the import timing for each item.

—: No import

Setting item	Import timing
Profile ID	When executing FB
Periodic	—
Input absolute coordinate	—
Output absolute coordinate	—
Operation profile data format	When executing FB
Profile data type	When executing FB
Interpolation method specification	—
Resolution/number of coordinates	—
Start point	—
Initial stroke amount	—
Initial velocity	—
Initial acceleration	—
Options	—
Number of positioning data settings	When executing FB
Total number of positioning data	When executing FB
Condition signal 1 to Condition signal 10 (ConditionSignal1 to ConditionSignal10)	When executing FB
Skip signal 1 to Skip signal 10 (SkipSignal1 to SkipSignal10)	When executing FB
Positioning data	When executing FB or during control (when pre-reading positioning data)
Length per cycle	—
Length unit setting per cycle	—
Length unit string per cycle	—
Minimum value per cycle	—
Maximum value per cycle	—
Time per cycle	—
Stroke amount	—
Stroke amount unit setting	—
Stroke amount unit string	—

Required object data

When using MCv_MovePositioningData (multiple axes positioning data operation), map the object assigned to the following object data to PDO for all configuration axes in the specified axes group.

- Target position (607AH)

If there is a configuration axis that does not map the above object to PDO, Required object data unset (error code: 1AF7H) will occur and the operation will not start.

For details on the object data settings, refer to the following.

☞ Page 466 Axis Assignment

Relevant add-ons

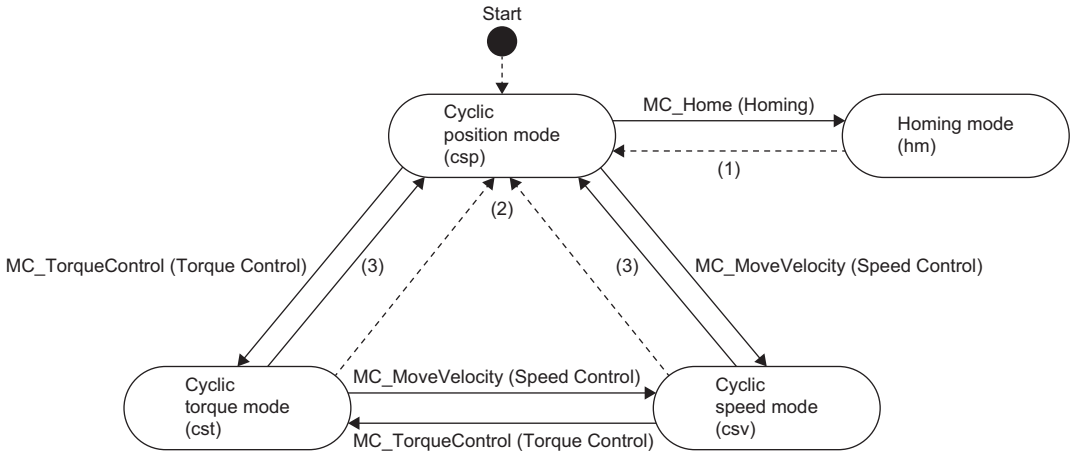
The following add-ons are required to use this function.

- MotionEngine
- MotionControl_General
- ProfileControl
- SignalIO*1

*1 When setting any of Condition signal 1 to Condition signal 10 (ConditionSignal1 to ConditionSignal10) and Skip signal 1 to Skip signal 10 (SkipSignal1 to SkipSignal10) of the operation profile data (multiple axes positioning data format)

29 DIRECT CONTROL

Direct control includes absolute position follow-up control, velocity control, torque control, and pressure control. The operation details of each control are as shown below.



Control name	Driver control mode	Applicable instruction	Operation details	Reference
Absolute position follow-up control	Cyclic synchronous position mode (csp)	MCv_PositionControl (Absolute Position Follow-up Control)	This function outputs the set position for each control cycle (Performs an operation with acceleration and deceleration)	Page 712 Absolute Position Follow-up Control
Velocity control	Cyclic synchronous position mode (csp)	MCv_SpeedControl (Speed Control (Including Position Loop))	This function outputs the set position based on the command velocity for each control cycle.	Page 715 Velocity Control
	Cyclic synchronous velocity mode (csv)	MC_MoveVelocity (Speed Control)	This function outputs the command velocity for each control cycle (excluding the position loop).	
Torque control	Cyclic synchronous torque mode (cst)	MC_TorqueControl (Torque Control)	This function outputs the command torque for each control cycle (excluding the position loop).	Page 726 Torque Control
Pressure control	Cyclic synchronous pressure mode (cspr)	MCv_PressureControl (Pressure Control)	This function outputs the command pressure for each control cycle (excluding the position loop).	Page 742 Pressure Control

Point

Creating a path, such as acceleration/deceleration for sending the target position, target velocity, and target torque to the drive unit, in the program is not required because the acceleration/deceleration function and torque ramp function exist. When the acceleration/deceleration function or torque ramp function is not used, refer to the motion cyclic control.

☞ Page 760 MOTION CYCLIC CONTROL

The control mode of the drive unit must be cyclic synchronous position mode (csp) when the unit is connected.
The switching of the drive unit control mode is simultaneously executed when the motion control FB is executed. The following shows the state transition.

No.	State transition description
(1)	Transits after the axis stops by homing completion or error occurrence.
(2)	Transits at stop completion or error occurrence.
(3)	Transits when Aborting or Buffered is executed to a motion control FB other than MC_MoveVelocity (Speed Control) and MC_TorqueControl (Torque Control).

Point

For usage such as pressing a workpiece using the MR-J5(W)-G, switch to the continuous operation to torque control mode (ct) by using torque control (MC_TorqueControl).
Using the continuous operation to torque control mode (ct) can switch the operation smoothly from the cyclic synchronous position mode or the cyclic synchronous velocity mode to the pressing operation. Therefore, reducing load to a machine and molding high in quality are provided as the velocity and torque do not change abruptly.
For details, refer to the following.
☞ Page 2165 Relevant functions

Operation of this function for each system status

○: Available, ×: Not available

System status	Operation availability
STOP	×
RUN	○
Moderate error	×
Major error	×

29.1 Absolute Position Follow-up Control

The target position of the absolute position is changed by restart/continuous update, and positioning control is performed without completing the instruction.

Relevant variables

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
SetPosition	Set Position	Stores the current position address.*1 The set position is a value where the cumulative current position is rounded within the ring counter range.
SetVelocity	Set Velocity	Stores the velocity calculated from the difference of the set position updated by the follow up.
SetAcceleration	Set Acceleration	Stores a value calculated from the difference of the set velocity.
SwStrokeLimit_Target	Software Stroke Limit Target	Displays the software stroke limit check method target.

*1 The stored value includes an error because a floating-point error occurs.

Relevant FB

For details on motion control FBs, refer to the following.

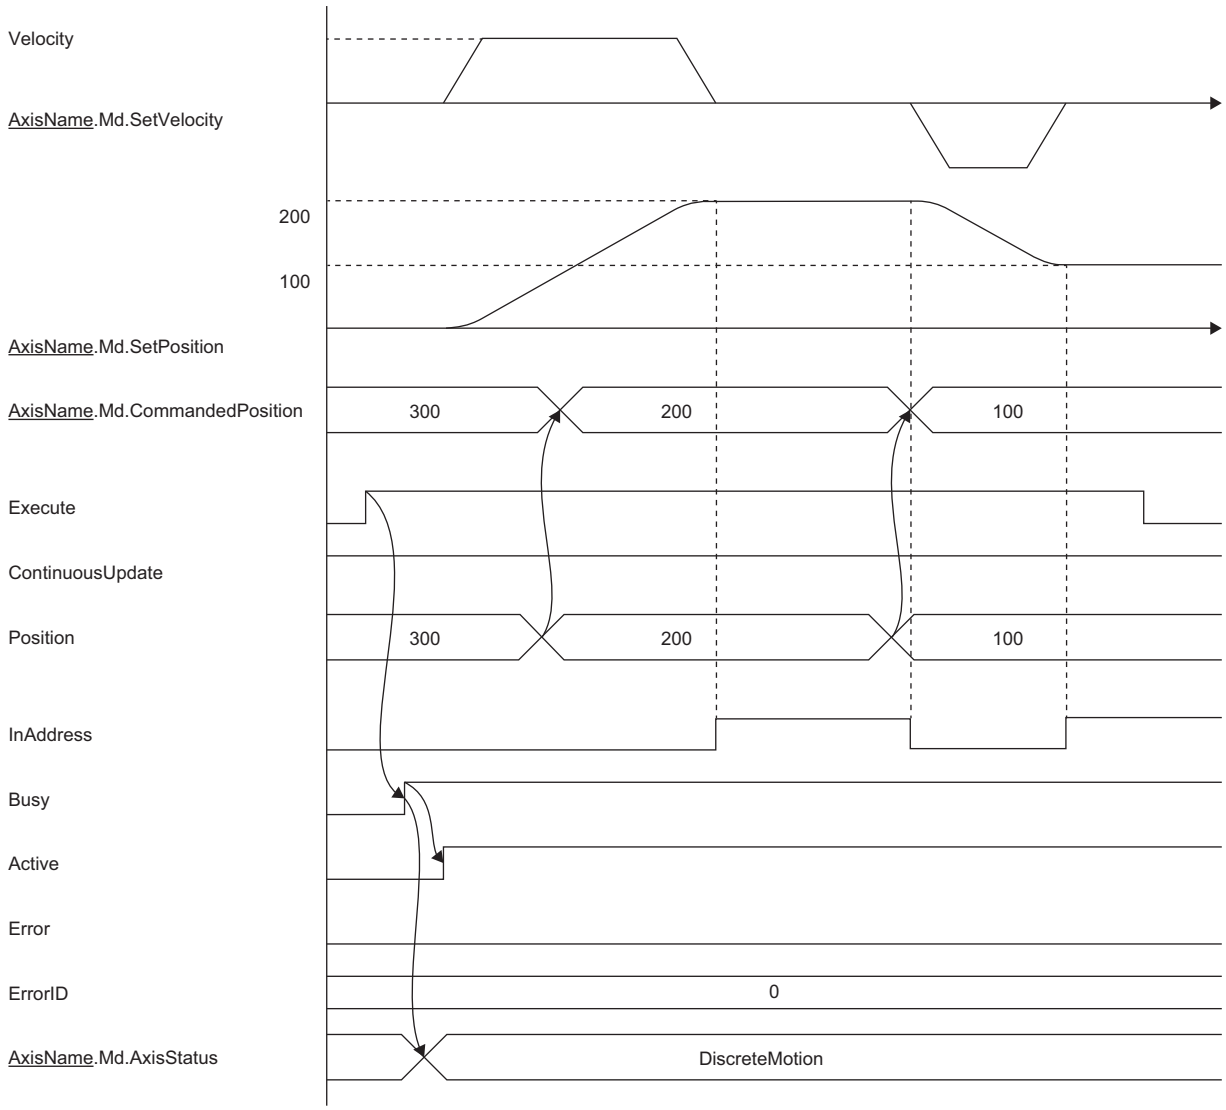
MELSEC MX Controller MX-R Model Programming Manual

Motion control FB	Name	Description
MCv_PositionControl	Absolute position follow-up control	This function moves the specified axis to the target position as follows. • Limit velocity • Acceleration • Deceleration • Jerk After the command reaches the target position, the target position can be changed by restart/continuous update and the axis can be moved.

Control details

MCv_PositionControl (Absolute Position Follow-up Control) moves the specified axis to the target position as follows.

- Limit velocity
- Acceleration
- Deceleration
- Jerk



After the command reaches the target position, the target position can be changed by restart/continuous update and the axis can be moved.

If the target position is changed before reaching the target position, the previous target position is ignored and the axis starts to move to the new target position.

To finish this FB, start MC_Stop (Forced Stop) or the other operation instruction.

Timing chart

■When the processing is completed successfully

■When the processing is completed with an error

For details when an error occurs, refer to "Basic operation of Execution command (Execute) type motion control FBs" in the following manual.

MELSEC MX Controller MX-R Model Programming Manual

Operation at stop cause occurrence

When a stop cause occurs during the axis operation, the axis will stop immediately or stop with deceleration depending on each cause. For details, refer to the following.

☞ Page 584 Stop causes during axis operation

Relevant object data

If no object data is set, PDO mapping is not performed, or no object exists in the device station, there will be errors and restrictions in the following function.

For details on the object data settings, refer to the following.

☞ Page 466 Axis Assignment

◎: Required

Instruction/function	Required object data	PDO mapping	Operation with no object
MCv_PositionControl (Absolute Position Follow-up Control)	Target position	◎	Required object data unset (error code: 1AF7H) occurs.

Precautions

If the target position (Position) and direction selection (Direction) are changed at the same time, data inconsistency may occur.

By changing the target position (Position) after changing the direction selection (Direction) first, both changes are applied when the target position (Position) is changed.

If the value of the target position (Position) and direction selection (Direction) must be changed at the same time, perform MCv_PositionControl (Absolute Position Follow-up Control) by fixed cycle program, or restart.

☞ Page 546 Retrigger/Continuous Update

29.2 Velocity Control

This control method switches the drive unit control mode to the cyclic synchronous velocity mode (csv), and performs the control excluding the position loop.

For speed control including position loop, refer to the following.

☞ Page 629 Single Axis Speed Control

Relevant variables

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
SetVelocity	Set Velocity	Stores the velocity calculated from the difference of the set position updated by the follow up.
SetAcceleration	Set Acceleration	Stores a value calculated from the difference of the set velocity.
TargetVelocity	Target Velocity	Stores the actual command velocity whose override and the velocity limit value are considered to Velocity (Velocity).
ActualVelocity	Actual Velocity	Stores the actual velocity (same as positioning control).
Io_TargetVelocity	Object Data_TargetVelocity	Displays the value of object data TargetVelocity. (The velocity command to send to devices)
Io_VelActualValue	Object Data_VelActualValue	Displays the value of object data_VelActualValue. (The actual velocity to be received from the device)
InVelocity	Target Velocity Reached	Indicates that Object Data_TargetVelocity (AxisName.Md.Io_TargetVelocity) has reached the target velocity.

Relevant FB

For details on motion control FBs, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

Motion control FB	Name	Description
MC_MoveVelocity	Speed Control	Switches the drive unit to the cyclic synchronous velocity mode (csv), and performs the velocity control based on the specified velocity.

Control details

MC_MoveVelocity (Speed Control) switches the drive unit control mode to the cyclic synchronous velocity mode (csv) and executes control. This function controls the command velocity based on the specified Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk). To finish this FB, start MC_Stop (Forced Stop).

Velocity initial value selection

Set the speed initial value when switching control mode from the cyclic synchronous position mode (csp) to the cyclic synchronous velocity mode (csv) to Velocity initial value selection (Options (Options): bit 16, 17).

- Cyclic synchronous position mode (csp) → Cyclic synchronous velocity mode (csv)

Setting value	Description
0: Command velocity	The velocity during command (AxisName.Md.SetVelocity) is used as the velocity commanded to the drive unit immediately after switching.
1: Actual velocity	Motor speed (AxisName.Io_VelActualValue) received from the drive unit at switching is used.*1
2: Automatic selection	The lower velocity between "0: Command velocity" and "1: Actual velocity" is used as the velocity commanded to the drive unit immediately after switching.*2

*1 When object data "Velocity actual value (606CH)" is not mapped, motor speed received from the drive unit at switching is not used. (Speed initial value selection becomes "0".)

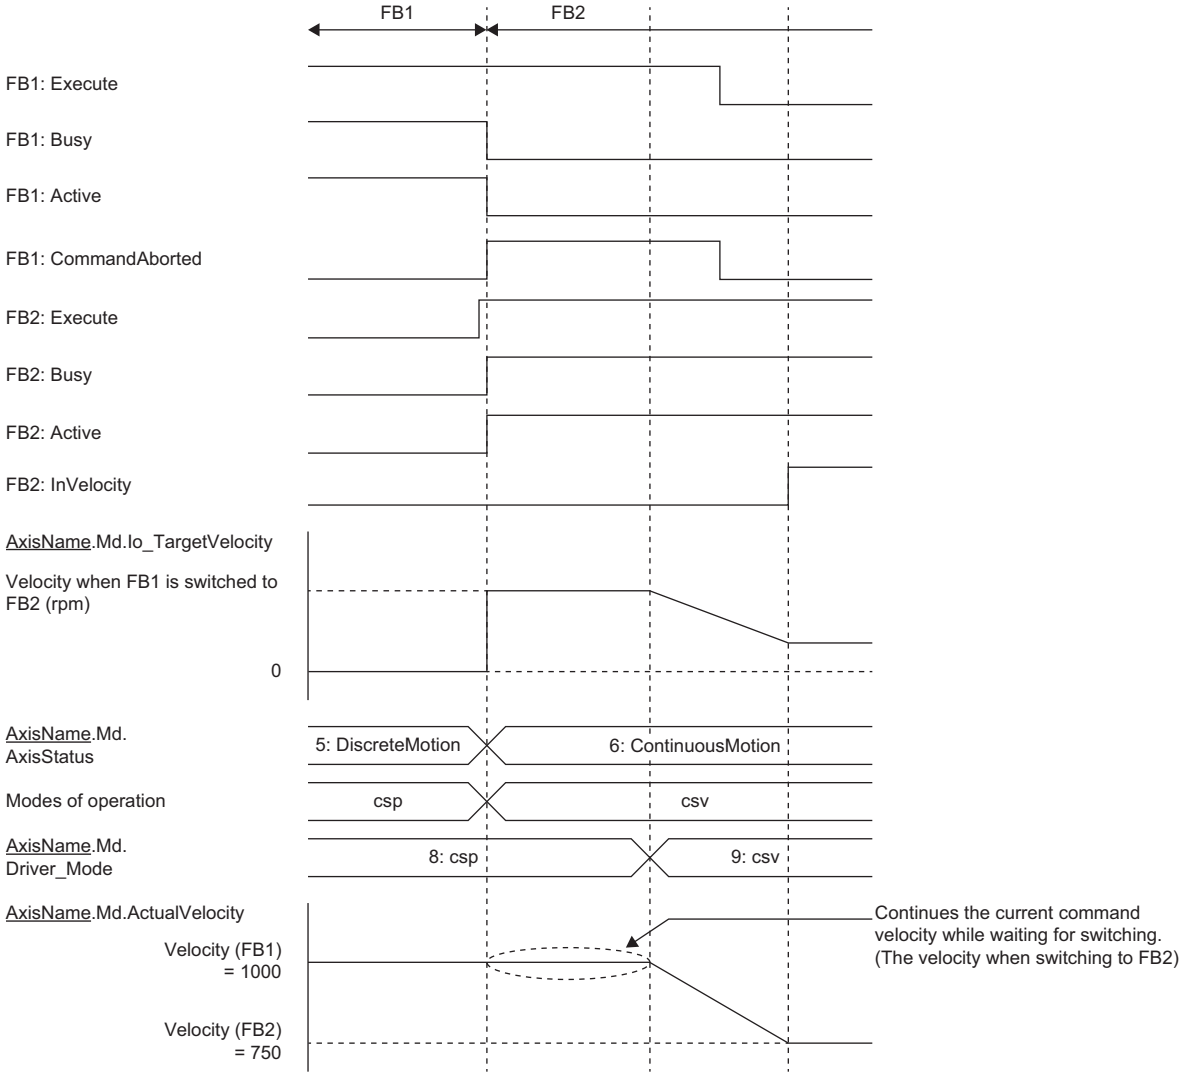
*2 When object data "Velocity actual value (606CH)" is not mapped, velocity commanded to the drive unit immediately after switching becomes "0: Command velocity".

Operation at stop cause occurrence

The following shows stop causes during the cyclic synchronous velocity mode (csv) and the process when each cause occurs.

Cause number	Stop cause	Axis Status (AxisName.Md.AxisStatus)		Stop process
		During deceleration stop	After stop	
1	"Forced stop input" is FALSE	—	1: Stopping on error (ErrorStop)	Immediate Stop[*1]
2	Drive unit power supply is FALSE Drive unit network disconnection detection Drive unit error Forced stop input to the drive unit Enable (Enable) of MC_Power (Operation Available) is FALSE Servo ON request (ServoON) of MC_Power (Operation Available) is FALSE (When Process Selection at Servo OFF Command During Operation (AxisName.Pr.StopMode_ServoOff) is "4: Servo OFF After Immediate Stop (ServoOffAfterImmediateStop)")[*2]	—	1: Stopping on error (ErrorStop)	Immediate Stop[*1]
3	Hardware stroke limit upper/lower limit error occurrence	1: Stopping on error (ErrorStop)	1: Stopping on error (ErrorStop)	Deceleration stop/Immediate stop (Follows Stop Selection at Hardware Stroke Limit Error Occurrence (AxisName.Pr.StopMode_HwStrokeLimit)) After stopping, the control mode switches to the cyclic synchronous position mode (csp).
4	Occurrence of a moderate or major error of the controller Occurrence of a moderate or major error of the built-in network function PLC READY (MotionSystem.Cd.SequenceReady) is off. Moderate error or major error of the motion system occurs Cycle over error occurrence	1: Stopping on error (ErrorStop)	1: Stopping on error (ErrorStop)	Deceleration stop/Immediate stop (Follows Stop Selection at All Axes Stop Cause Occurrence (MotionSystem.Pr.StopMode_All)) After stopping, the control mode switches to the cyclic synchronous position mode (csp).
5	Software stroke limit upper/lower limit error occurrence	1: Stopping on error (ErrorStop)	1: Stopping on error (ErrorStop)	Deceleration stop/Immediate stop (Follows Stop Selection at Software Stroke Limit Error Occurrence (AxisName.Pr.StopMode_SwStrokeLimit)) After stopping, the control mode switches to the cyclic synchronous position mode (csp).
6	Axis error detection[*3]	1: Stopping on error (ErrorStop)	1: Stopping on error (ErrorStop)	Deceleration stop/Immediate stop (Follows Stop Selection at Stop Cause Occurrence (AxisName.Pr.StopMode_General)) After stopping, the control mode switches to the cyclic synchronous position mode (csp).
7	Execution command (Execute) of MC_Stop (Forced Stop) is TRUE	2: Decelerating to stop (Stopping)	2: Decelerating to stop (Stopping)[*4]	Deceleration stop (Follows the deceleration speed set in the FB) After stopping, the control mode switches to the cyclic synchronous position mode (csp).
8	"Stop signal (STOP)" of external input signal is TRUE	No change	4: Standby (Standstill)	Deceleration stop/Immediate stop (Follows Stop Selection at Stop Cause Occurrence (AxisName.Pr.StopMode_General)) After stopping, the control mode switches to the cyclic synchronous position mode (csp).

*1 The servo turns off on the drive unit side and immediate stop is performed, and also the motion system side command is stopped.
*2 Operation differs depending on the setting of Process Selection at Servo OFF Command During Operation (AxisName.Pr.StopMode_ServoOff). For details, refer to the following.
☞ Page 592 Stop causes by Servo ON request (ServoON) input of MC_Power (Operation Available)
*3 If an axis error (the error that transits the status into the "1: Stopping on error (ErrorStop)" status) occurs in the buffering FB, immediate stop will be performed upon the occurrence of the error.
*4 When Execution command (Execute) of MC_Stop (Forced Stop) is FALSE at stop completion, Axis Status (AxisName.Md.AxisStatus) after stop will be "4: Standby (Standstill)".



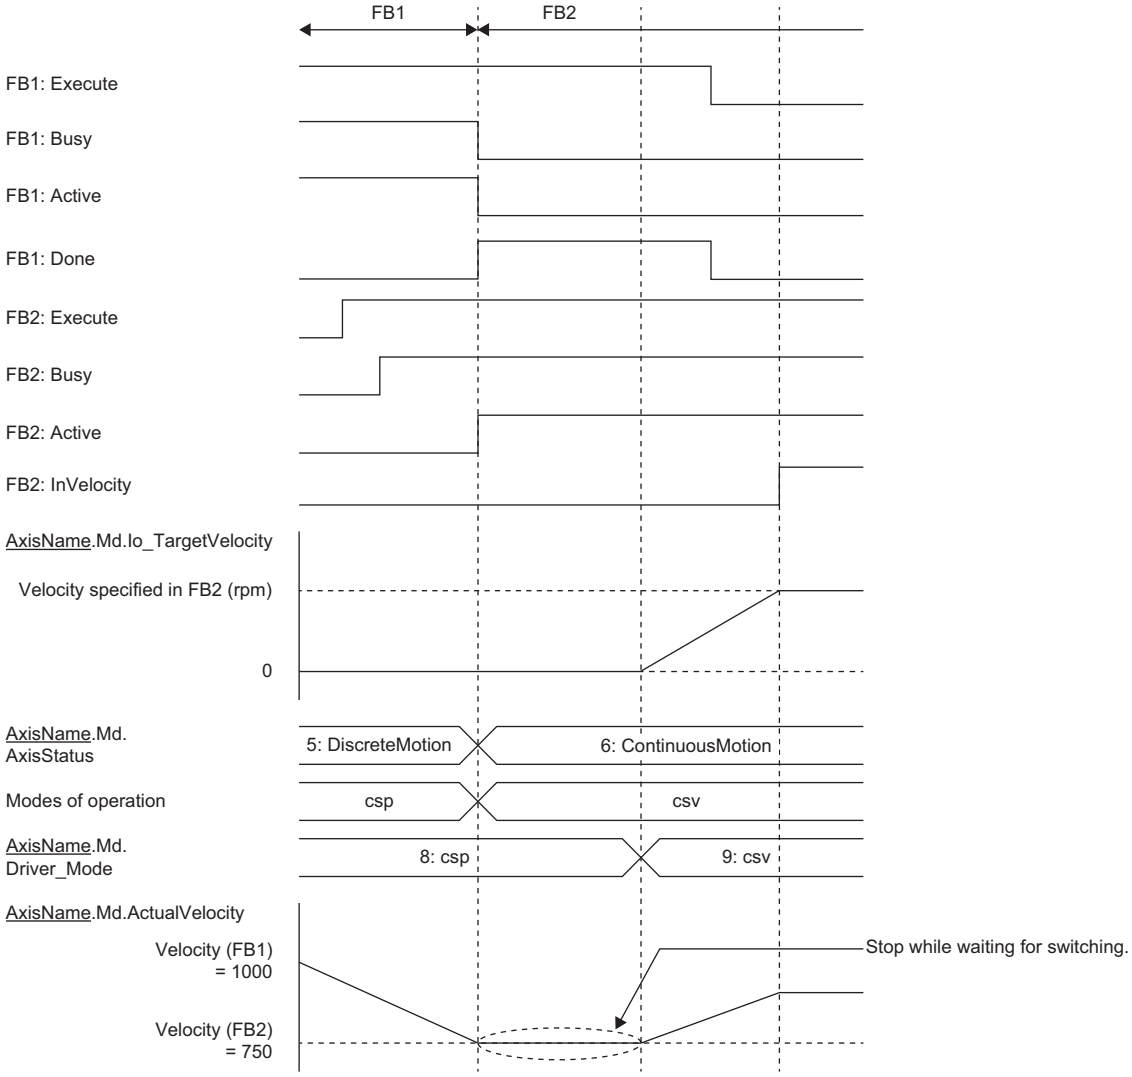
Buffer mode (BufferMode)

When starting this FB during another instruction execution

■Single axis position control (FB1) → Velocity control (FB2)

• 0: Aborting (mcAborting)

1. Input variables are analyzed, and a switching request to the cyclic synchronous velocity mode (csv) is issued to the drive unit.
2. Until the drive unit is switched, the axis is operated at the previous velocity with velocity control including the position loop.
3. When the drive unit switches to the cyclic synchronous velocity mode (csv), Target Velocity (TargetVelocity) is obtained based on the actual velocity and the acceleration/deceleration process is started again.



• 1: Buffered (mcBuffered)

1. Input variables are analyzed, and the axis waits until the previous instruction is completed.

2. When the previous instruction is completed, a switching request to the cyclic synchronous velocity mode (csv) is issued to the drive unit.

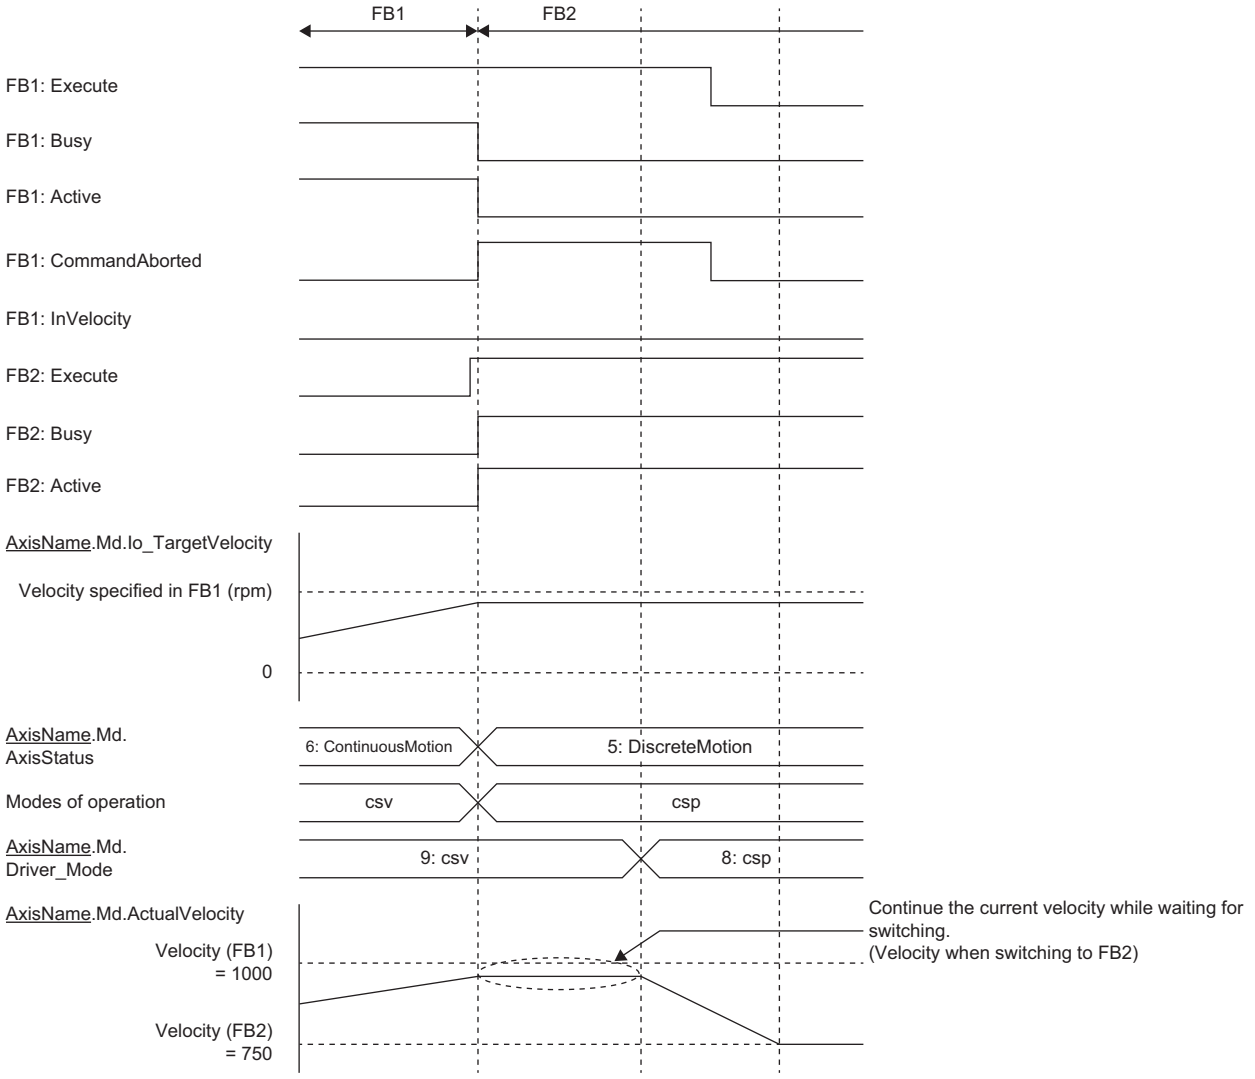
3. When the drive unit switches to the cyclic synchronous velocity mode (csv), the acceleration/deceleration process is started based on the settings of FB2.

When starting another instruction during this FB execution

While this FB is executed, only Aborting and Buffered are supported.

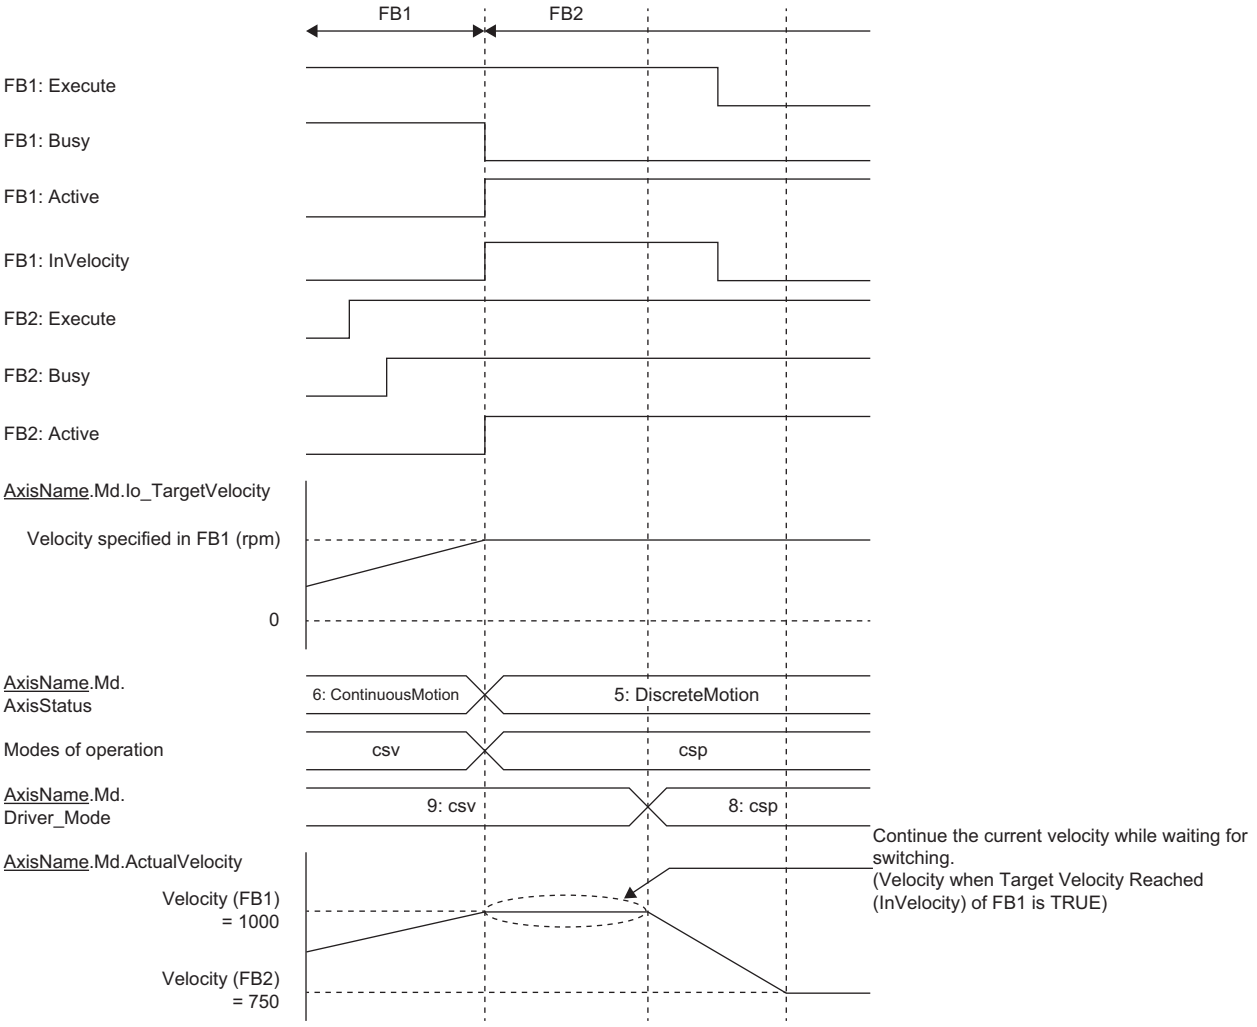
■Velocity control → Operation at positioning start

1. A switching request to the cyclic synchronous position mode (csp) is issued to the drive unit.
2. The positioning control FB that was started is analyzed, and the axis waits until the drive unit switches to the cyclic synchronous position mode (csp). (Even if a switching request to the cyclic synchronous position mode (csp) is executed during axis operation, switching may not be carried out depending on the drive unit specifications. If switching to the cyclic synchronous position mode (csp) is not completed within 1 [s], Control mode switching error (error code: 1A95H) occurs due to timeout and the axis stops.)
3. While waiting, velocity control is continued with the command velocity when Execution command (Execute) of FB2 is TRUE.
4. When the drive unit switches to the cyclic synchronous position mode (csp), the positioning control starts.



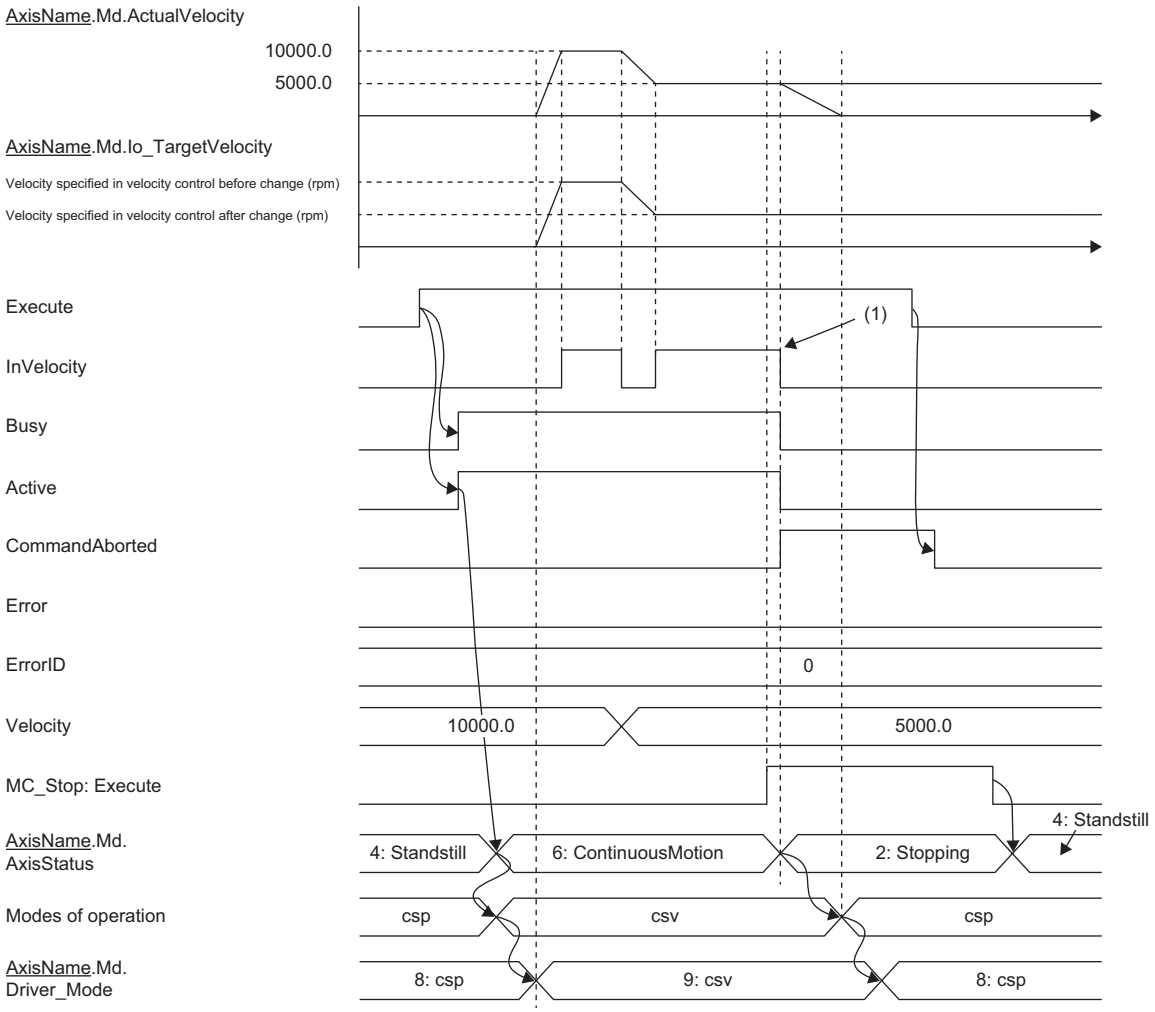
Point

- The deceleration distance may not be secured and the target position may be overrun depending on the travel distance switching from the cyclic synchronous velocity mode (csv) to the cyclic synchronous position mode (csp). In this case, the axis operates based on Operation Setting at Overrun (AxisName.Pr.OverrunOperation).



☞ Page 547 Multiple Start (Buffer Mode)

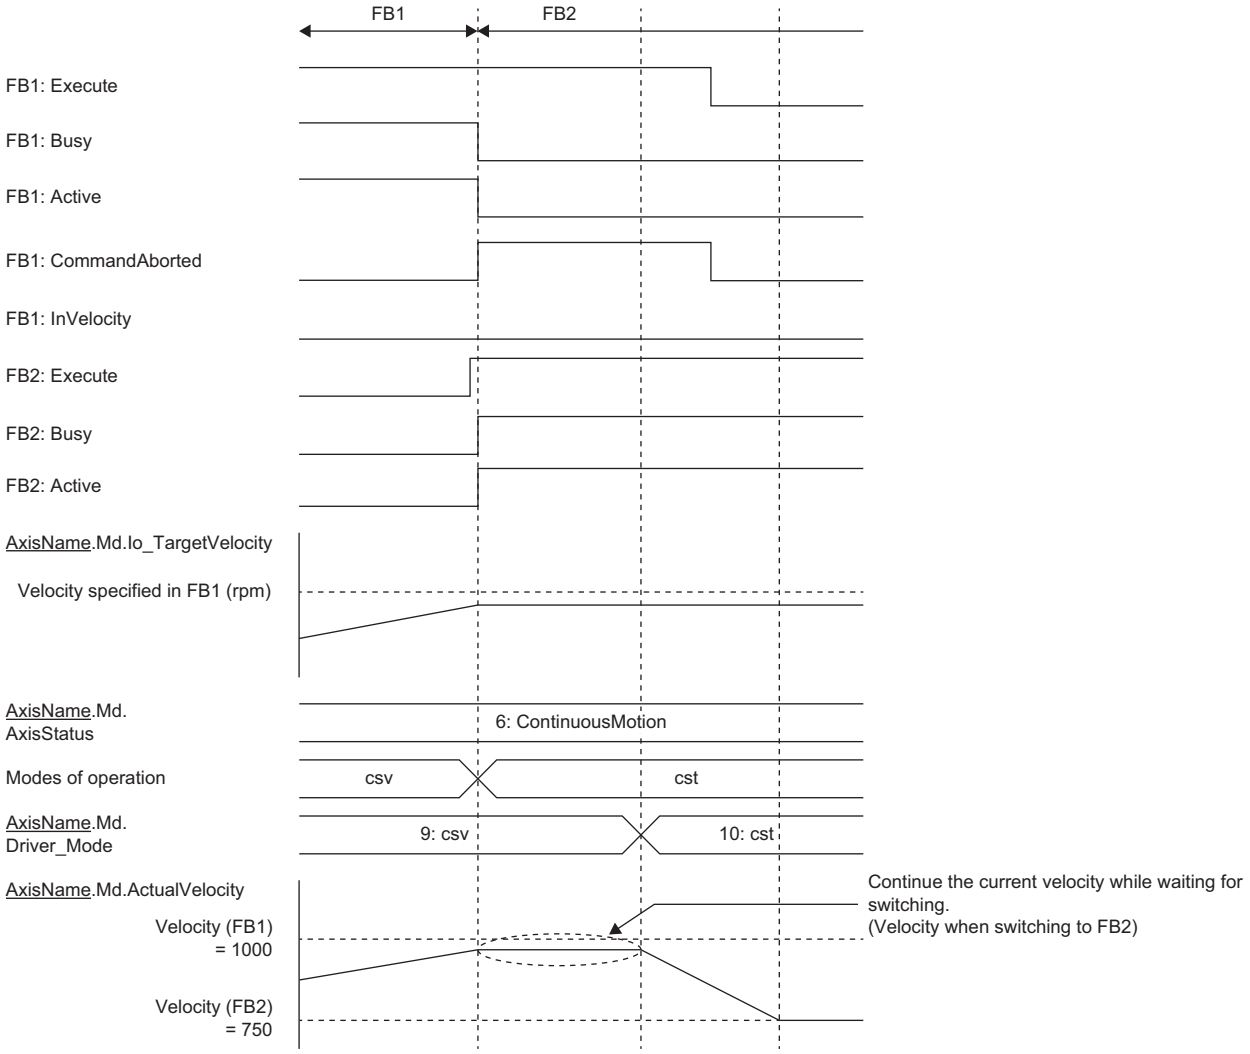
- If an overrun occurs while waiting for switching, Overrun error (error code: 1AE3H) will occur immediately after switching to the cyclic synchronous position mode (csp), and the motor will stop immediately, regardless of Operation Setting at Overrun (AxisName.Pr.OverrunOperation).



• 0: Aborting (mcAborting)

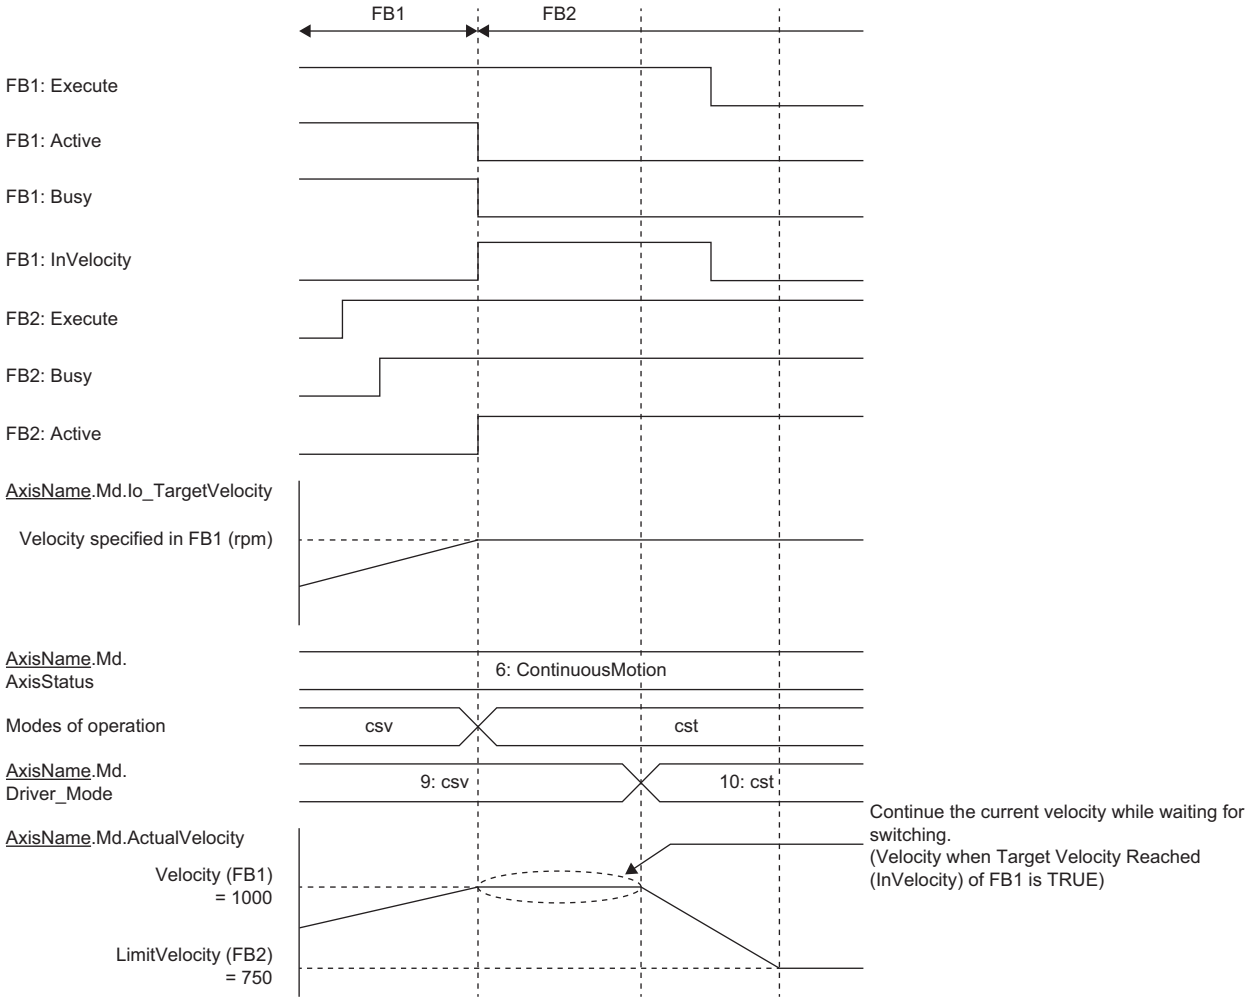
• 1: Buffered (mcBuffered)

■Speed control → Stop instruction (MC_Stop (Forced Stop))



(1) MC_Stop (Forced Stop) is started.

■Speed control → Torque control



1. A switching request to the cyclic synchronous torque mode (cst) is executed to the drive unit.

2. The torque control that was started is analyzed, and the axis waits until the drive unit switches to the cyclic synchronous torque mode (cst).

• 0: Aborting (mcAborting)

• 1: Buffered (mcBuffered)

When the operation direction is reversed

When starting this FB and operation direction is reversed during another instruction execution, a deceleration stop is performed once.

After the deceleration stop is completed, operation is started in the changed direction.

Relevant object data

If no object data is set, PDO mapping is not performed, or no object exists in the device station, there will be errors and restrictions in the following function.

For details on the object data settings, refer to the following.

☞ Page 466 Axis Assignment

◎: Required, ○: Recommended

Instruction/function	Required object data	PDO mapping	Operation with no object
MC_MoveVelocity (Speed Control)	Target velocity	◎	Required object data unset (error code: 1AF7H) occurs.
	Velocity actual value	○	☞ Page 715 Velocity initial value selection

Precautions

- Velocity Override Factor (AxisName.Cd.VelocityOverride) and Acceleration Override Factor (AxisName.Cd.AccelerationOverride) are valid.
- The set position and the machine feed value are updated by follow up.
- Time until the control mode is switched depends on the specifications of the drive unit.
- When the stop cause occurs during the control mode switching, the axis will stop immediately.
- Do not start the positioning control FB during the control mode switching. Start the positioning control FB after checking that Driver Control Mode (AxisName.Md.Driver_Mode) is switched to "9: csv (Velocity Control) (csv)".
- When switching the control mode from the cyclic synchronous position mode (csp) to the cyclic synchronous velocity mode (csv), if a stop cause (axis error detection) occurs before the control mode is switched, follow-up may continue in cyclic synchronous position mode (csp) until the zero speed status is reached.
- When switching from the cyclic synchronous position mode (csp) to the cyclic synchronous velocity mode (csv) or from the cyclic synchronous velocity mode (csv) to the cyclic synchronous position mode (csp) without waiting for stop of the motor by using the MR-J5(W)-G, note the following.
  - Set the servo parameter (extension setting) "ZSP disabled selection at control switching (PC76.1)" to "1: Disabled" and disable monitoring of zero speed status. However, note that it may cause vibration or impact at control mode switching.
  - For the setting value of the servo parameter "Electronic gear numerator (PA06)" and "Electronic gear denominator (PA07)", refer to the following. ☞ Page 2152 Setting method

29.3 Torque Control

This control method switches the drive unit control mode to the cyclic synchronous torque mode (cst), and performs the control.

Relevant variables

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
SetVelocity	Set Velocity	Stores the velocity calculated from the difference of the set position updated by the follow up.
SetAcceleration	Set Acceleration	Stores a value calculated from the difference of the set velocity.
TargetVelocity	Target Velocity	Stores value set to the limit velocity (LimitVelocity) The value becomes 0 or more regardless of the movement direction. Stores 0 after the control is completed.
ActualVelocity	Actual Velocity	Stores the actual velocity (same as positioning control).
Cst_SetTorque	Set Torque at cst/ct	Stores the current command torque in the cyclic synchronous torque mode (cst) and the continuous operation to torque control mode (ct).
Cst_TargetTorque	Target Torque at cst/ct	Stores the target torque in the cyclic synchronous torque mode (cst) and the continuous operation to torque control mode (ct).
Cst_SetLimitVelocity	Set Limit Velocity at cst/ct/cspr	Stores the command limit velocity in the cyclic synchronous torque mode (cst), continuous operation to torque control mode (ct), and cyclic synchronous pressure mode (cspr).
Io_TorqueActualValue	Object Data_TorqueActualValue	Displays the value of object data_TorqueActualValue. (The actual torque to be received from the device)
Io_VelActualValue	Object Data_VelActualValue	Displays the value of object data_VelActualValue. (The actual velocity to be received from the device)
InVelocity	Target Velocity Reached	Stores FALSE in the cyclic synchronous torque mode (cst) and the continuous operation to torque control mode (ct).

Relevant FB

For details on motion control FBs, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

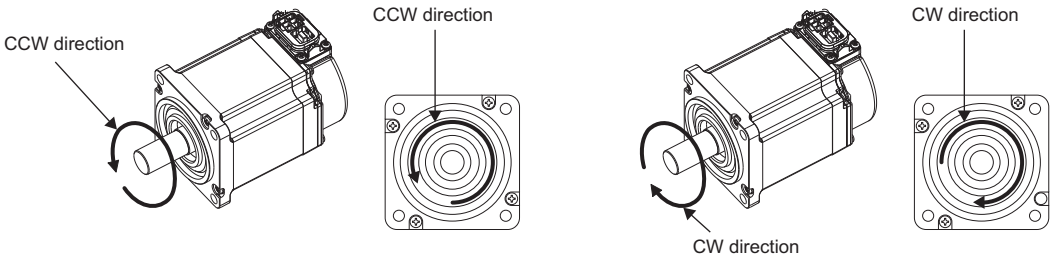
Motion control FB	Name	Description
MC_TorqueControl	Torque control	Switches the drive unit to the cyclic synchronous torque mode (cst), and executes the torque control based on the specified target torque.

Control details

MC_TorqueControl (Torque Control) switches the drive unit control mode to the cyclic synchronous torque mode (cst) and executes control. This function controls the set torque based on the specified Torque positive direction ramp (TorquePositiveRamp) and Torque negative direction ramp (TorqueNegativeRamp). To finish this FB, start MC_Stop (Forced Stop).

Relation between torque generation direction of servo motor and set torque

When using the MR-J5(W)-G, it differs based on the settings of the servo parameter "Movement direction selection (PA14)" and "Torque POL reflection selection (PC29.3)".



- When the servo parameter (extension setting) "Torque POL reflection selection (PC29.3)" is set to "0: Enabled"

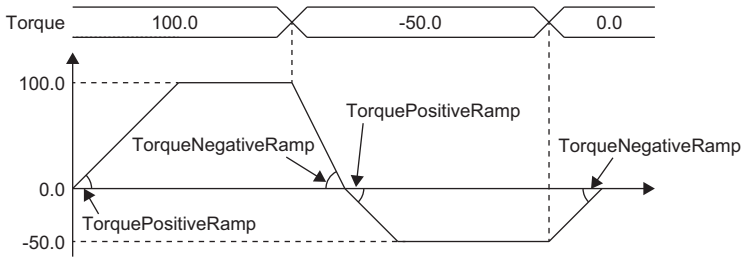
Setting value of "Travel direction selection (PA14)"	Set torque	Torque generation direction of servo motor
0: Positioning address increasing CCW rotation	Positive value (positive direction)	CCW direction*1
	Negative value (negative direction)	CW direction*1
1: Positioning address increasing CW rotation	Positive value (positive direction)	CW direction*1
	Negative value (negative direction)	CCW direction*1

- When the servo parameter (extension setting) "Torque POL reflection selection (PC29.3)" is set to "1: Disabled" (Initial value)

Setting value of "Travel direction selection (PA14)"	Set torque	Torque generation direction of servo motor
0: Positioning address increasing CCW rotation	Positive value (positive direction)	CCW direction*1
	Negative value (negative direction)	CW direction*1
1: Positioning address increasing CW rotation	Positive value (positive direction)	CCW direction*1
	Negative value (negative direction)	CW direction*1

*1 For details, refer to the following illustration.

Torque ramp function selection (Options (Options): bit 16, 17)

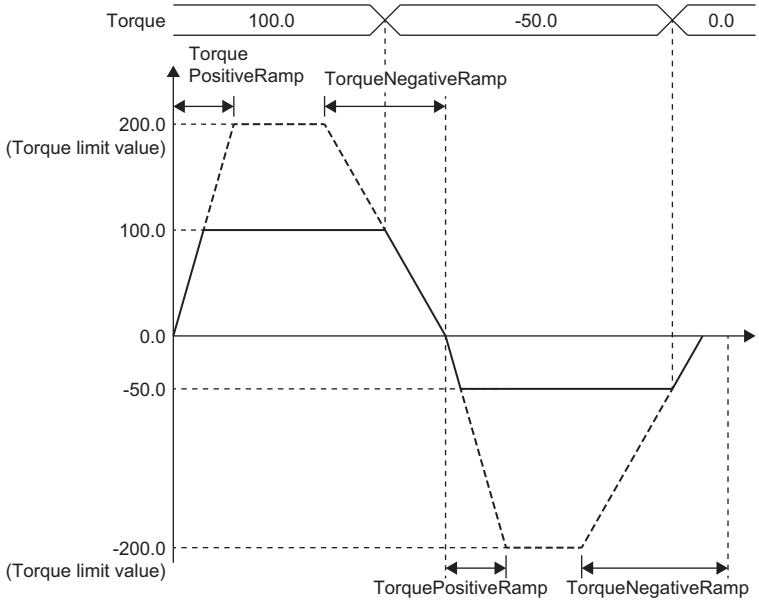


Set the method from set torque until the target torque is reached.

Torque positive direction ramp (TorquePositiveRamp) and Torque negative direction ramp (TorqueNegativeRamp) differ depending on the setting values.

■For "0: Ramp method"

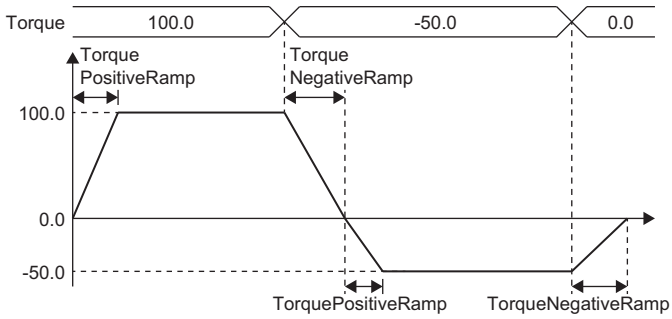
Specify the ramp from the current set torque until the target torque is reached.



Setting range
0.0 to 1000.0 [%/s]

■For "1: Time constant method"

Set the time until the set torque reaches the positive/negative torque limit value from "0".



Setting range
0.0 to 8400.0 [s]

■For "2: Fixed time method"

Set the time from the current set torque until the target torque is reached.

Setting range
0.0 to 8400.0 [s]

When the output torque direction is changed due to the target torque change, the set torque becomes "0.0" based on the setting value of the torque negative direction ramp. After that, it becomes the target torque based on the setting value of the torque positive direction ramp.

When the torque positive direction ramp and the torque negative direction ramp are set to "0.0", the value reaches the target torque in one operation cycle.

Torque initial value selection (Options (Options): bit 18)

Set the torque initial value when switching to the cyclic synchronous torque mode (cst).

Setting value	Description
0: Target torque	Target torque (Torque) value at start is set as the set torque regardless of the value of torque positive direction ramp and torque negative direction ramp immediately after the control mode switching.
1: Actual torque	Torque actual value at switching is set as the set torque.*1

*1 When the object assigned to object data Torque actual value is not mapped to PDO, actual torque received from the drive unit at switching is not used. The torque initial value is 0.

Point

Normally, set this bit to "0: Target torque". Set "1: Actual torque" only when switching the control mode immediately after the command to the motor is completed without waiting for the servo motor to stop.

Operation at stop cause occurrence

The following shows stop causes during the cyclic synchronous torque mode (cst) and the process when each cause occurs.

Cause number	Stop cause	Axis Status (AxisName.Md.AxisStatus)	Stop process
		After stop	
1	"Forced stop input" is FALSE	1: Stopping on error (ErrorStop)	Immediate Stop[*1]
2	Drive unit power supply is FALSE	1: Stopping on error (ErrorStop)	Immediate Stop[*1]
	Drive unit network disconnection detection		
	Drive unit error		
	Forced stop input to the drive unit		
	Enable (Enable) of MC_Power (Operation Available) is FALSE		
	Servo ON request (ServoON) of MC_Power (Operation Available) is FALSE (When Process Selection at Servo OFF Command During Operation (AxisName.Pr.StopMode_ServoOff) is "4: Servo OFF After Immediate Stop (ServoOffAfterImmediateStop)" or "5: Servo OFF After Deceleration to Stop (ServoOffAfterDecelStop)")[*2]		
3	Hardware stroke limit upper/lower limit error occurrence	1: Stopping on error (ErrorStop)	The limit velocity is changed to 0, and an immediate stop is performed.[*5] After stopping, the control mode switches to the cyclic synchronous position mode (csp).
4	Occurrence of a moderate or major error of the controller	1: Stopping on error (ErrorStop)	
	Occurrence of a moderate or major error of the built-in network function		
	PLC READY (MotionSystem.Cd.SequenceReady) is off.		
	Moderate error or major error of the motion system occurs		
	Cycle over error occurrence		
5	Software stroke limit upper/lower limit error occurrence	1: Stopping on error (ErrorStop)	
6	Axis error detection[*3]	1: Stopping on error (ErrorStop)	
7	Execution command (Execute) of MC_Stop (Forced Stop) is TRUE	2: Decelerating to stop (Stopping)[*4]	The limit velocity is changed to 0, and an immediate stop is performed.[*5] After stopping, the control mode switches to the cyclic synchronous position mode (csp). (Not based on the deceleration of MC_Stop (Forced Stop))
8	"Stop signal (STOP)" of external input signal is TRUE	4: Standby (Standstill)	The limit velocity is changed to 0, and an immediate stop is performed.[*5] After stopping, the control mode switches to the cyclic synchronous position mode (csp).

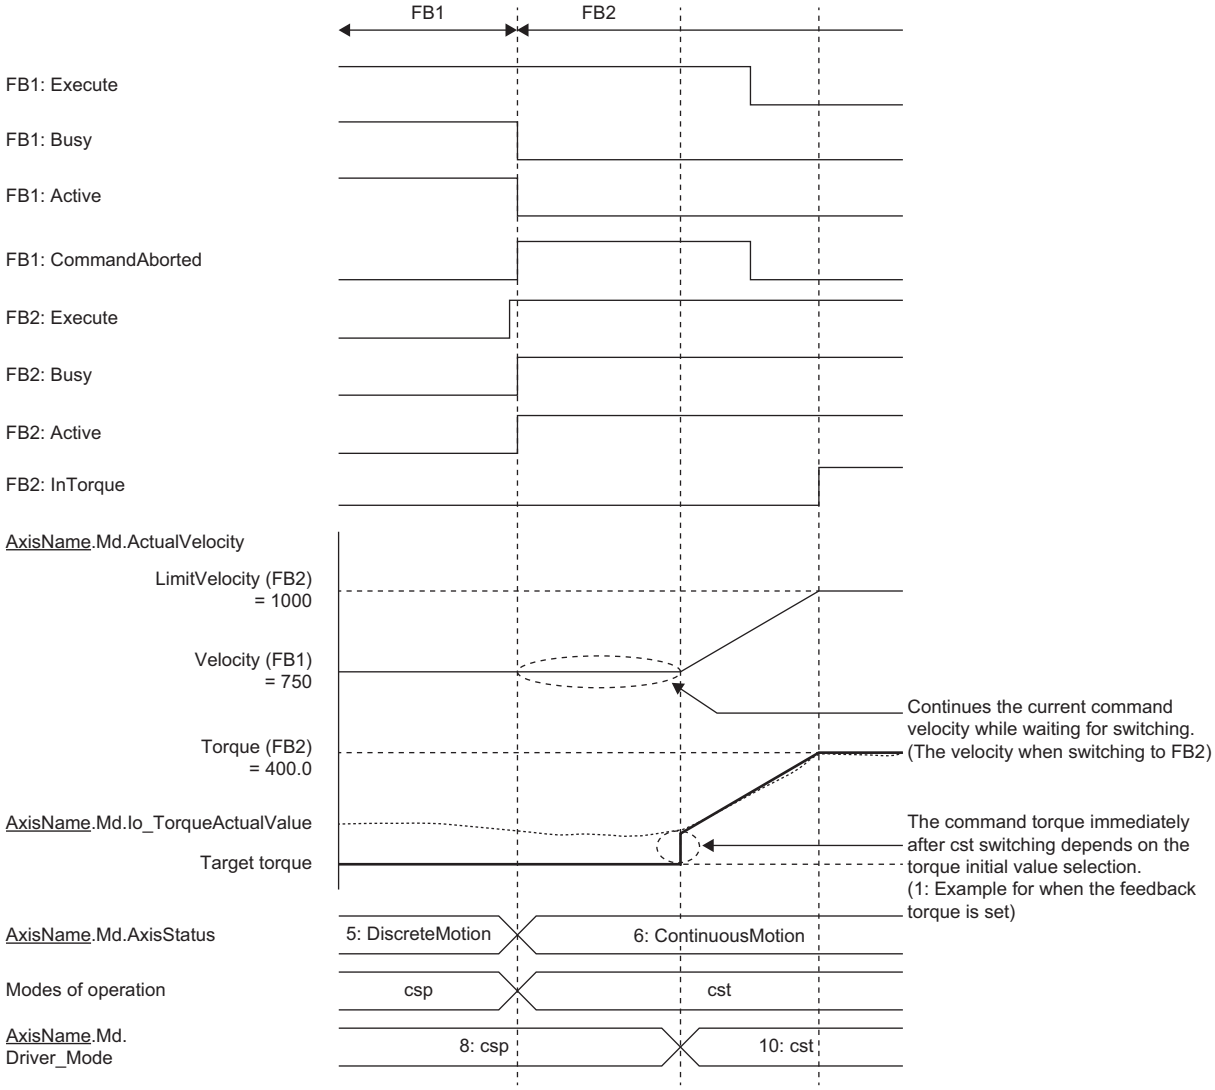
*1 The servo turns off on the drive unit side and immediate stop is performed, and also the motion system side command is stopped.

*2 Operation differs depending on the setting of Process Selection at Servo OFF Command During Operation (AxisName.Pr.StopMode_ServoOff). For details, refer to the following.
☞ Page 579 Relevant variables

*3 If an axis error (the error that transits the status into the "1: Stopping on error (ErrorStop)" status) occurs in the buffering FB, immediate stop will be performed upon the occurrence of the error.

*4 When Execution command (Execute) of MC_Stop (Forced Stop) is FALSE at stop completion, Axis Status (AxisName.Md.AxisStatus) after stop will be "4: Standby (Standstill)".

*5 The set torque value is not changed. Note that it may take time to reach velocity 0 depending on the torque command value that is currently specified.

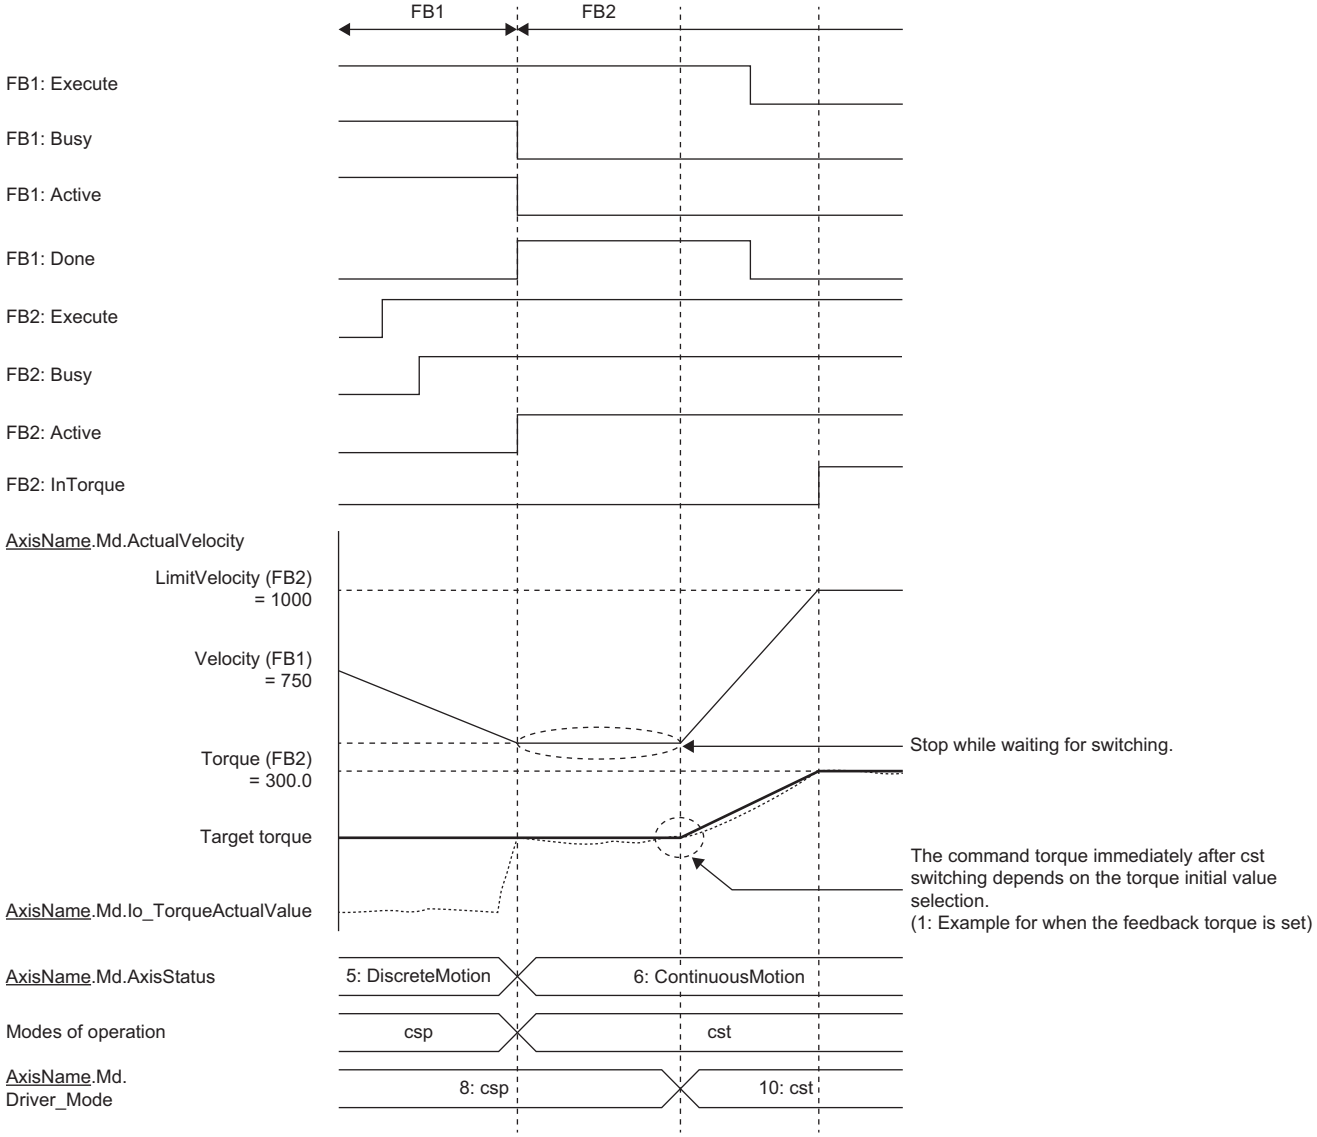


When starting this FB during another instruction execution

While this FB is executed, only Aborting and Buffered are supported.

■Position control (FB1) → Torque control (FB2)

- 0: Aborting (mcAborting)

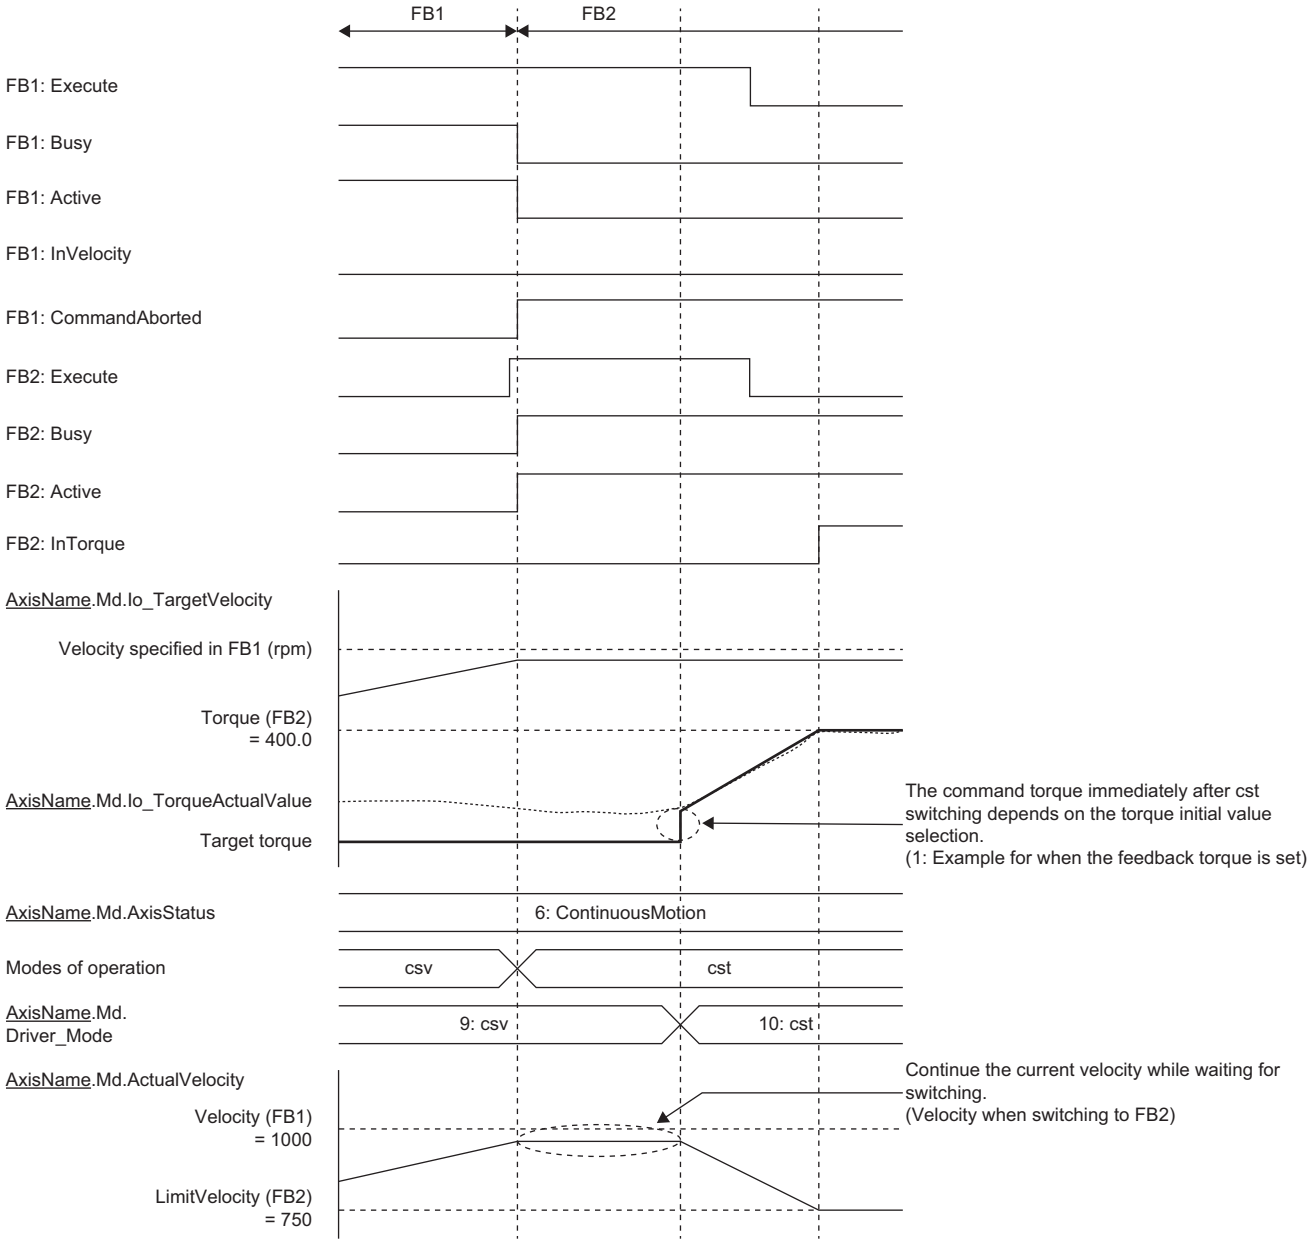


1. A switching request to the cyclic synchronous torque mode (cst) is issued to the drive unit.
2. Until the drive unit is switched, the axis is operated at the previous velocity with velocity control including the position loop.
3. When the drive unit switches to the cyclic synchronous torque mode (cst), the torque increase/decrease is started from the current actual torque, and the acceleration/deceleration process of the velocity limit value is started from the current command velocity.

• 1: Buffered (mcBuffered)

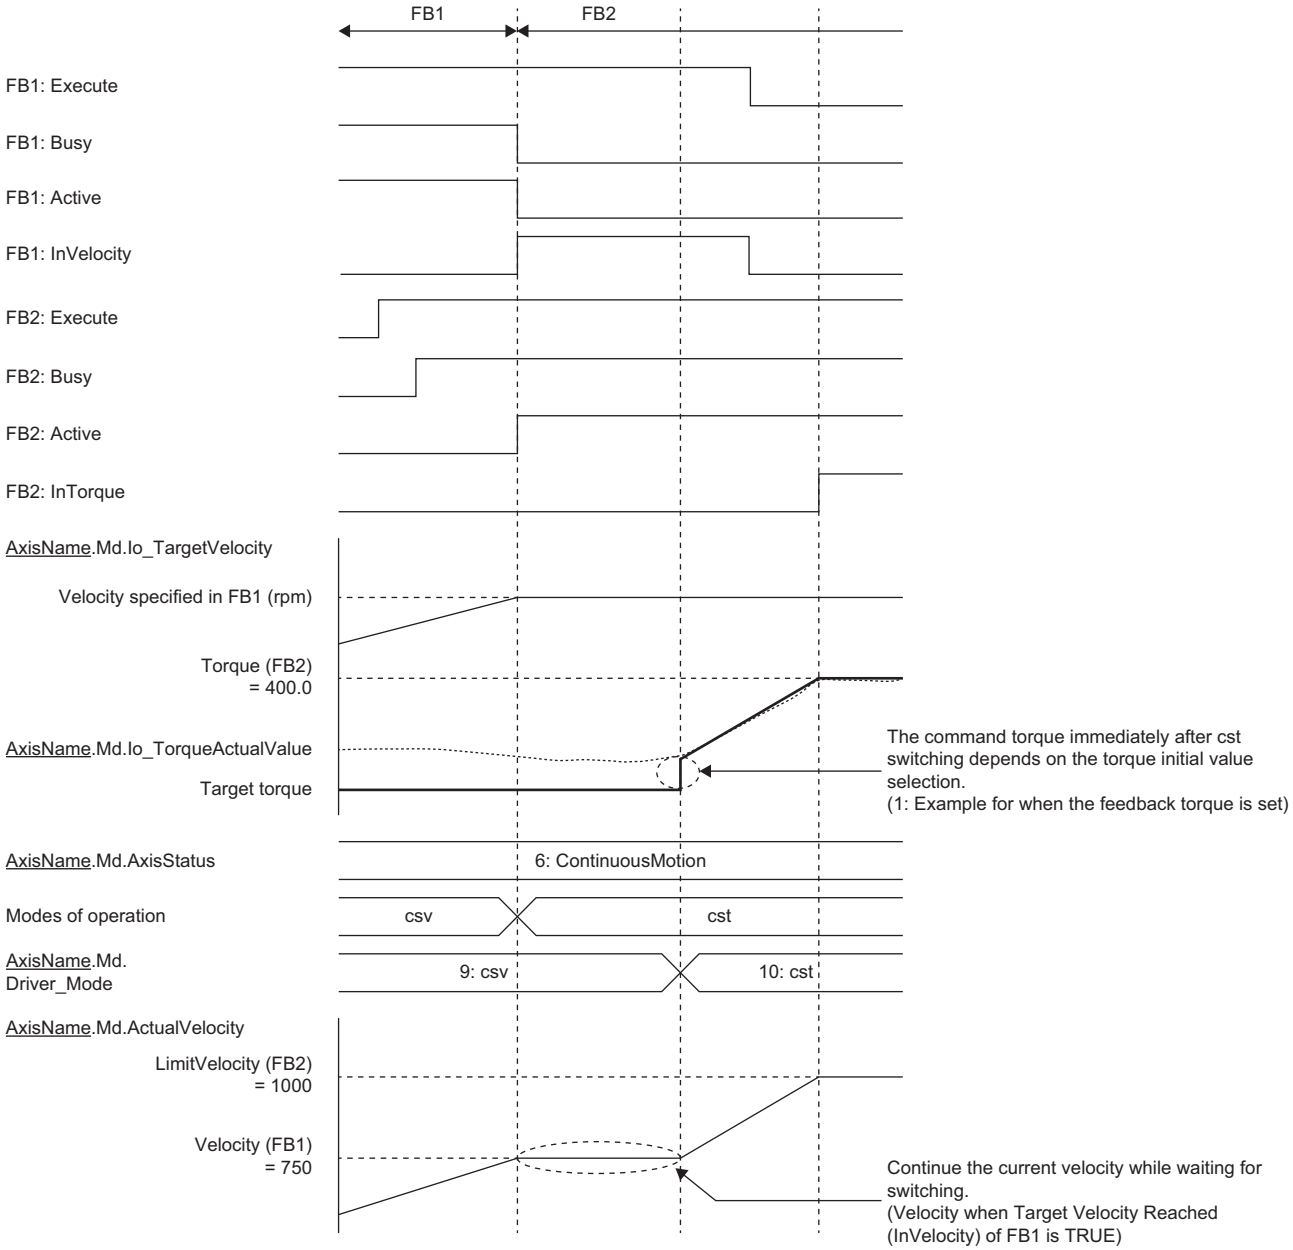
1. When the first instruction is completed, a cyclic synchronous torque mode (cst) change request is issued to the drive unit.

2. When the drive unit switches to the cyclic synchronous torque mode (cst), the acceleration/deceleration process of the torque and the velocity is started from the current actual torque and the command velocity.



■Speed control (FB1) → Torque control (FB2)

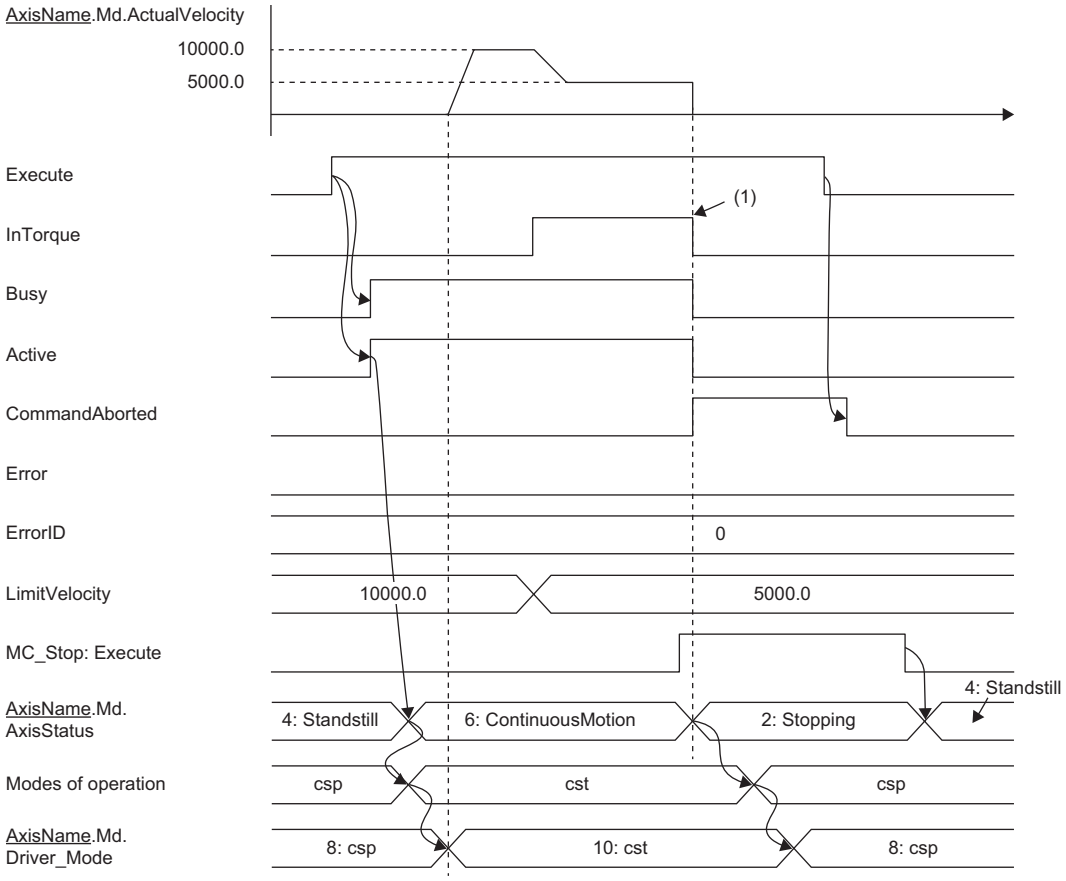
1. A cyclic synchronous torque mode (cst) change request is issued to the drive unit.



2. While waiting for change, the cyclic synchronous velocity mode (csv) is continued.

3. When the drive unit switches to the cyclic synchronous torque mode (cst), the torque increase/decrease is started from the current actual torque, and the acceleration/deceleration process of the velocity is started from the command velocity.

• 0: Aborting (mcAborting)



• 1: Buffered (mcBuffered)

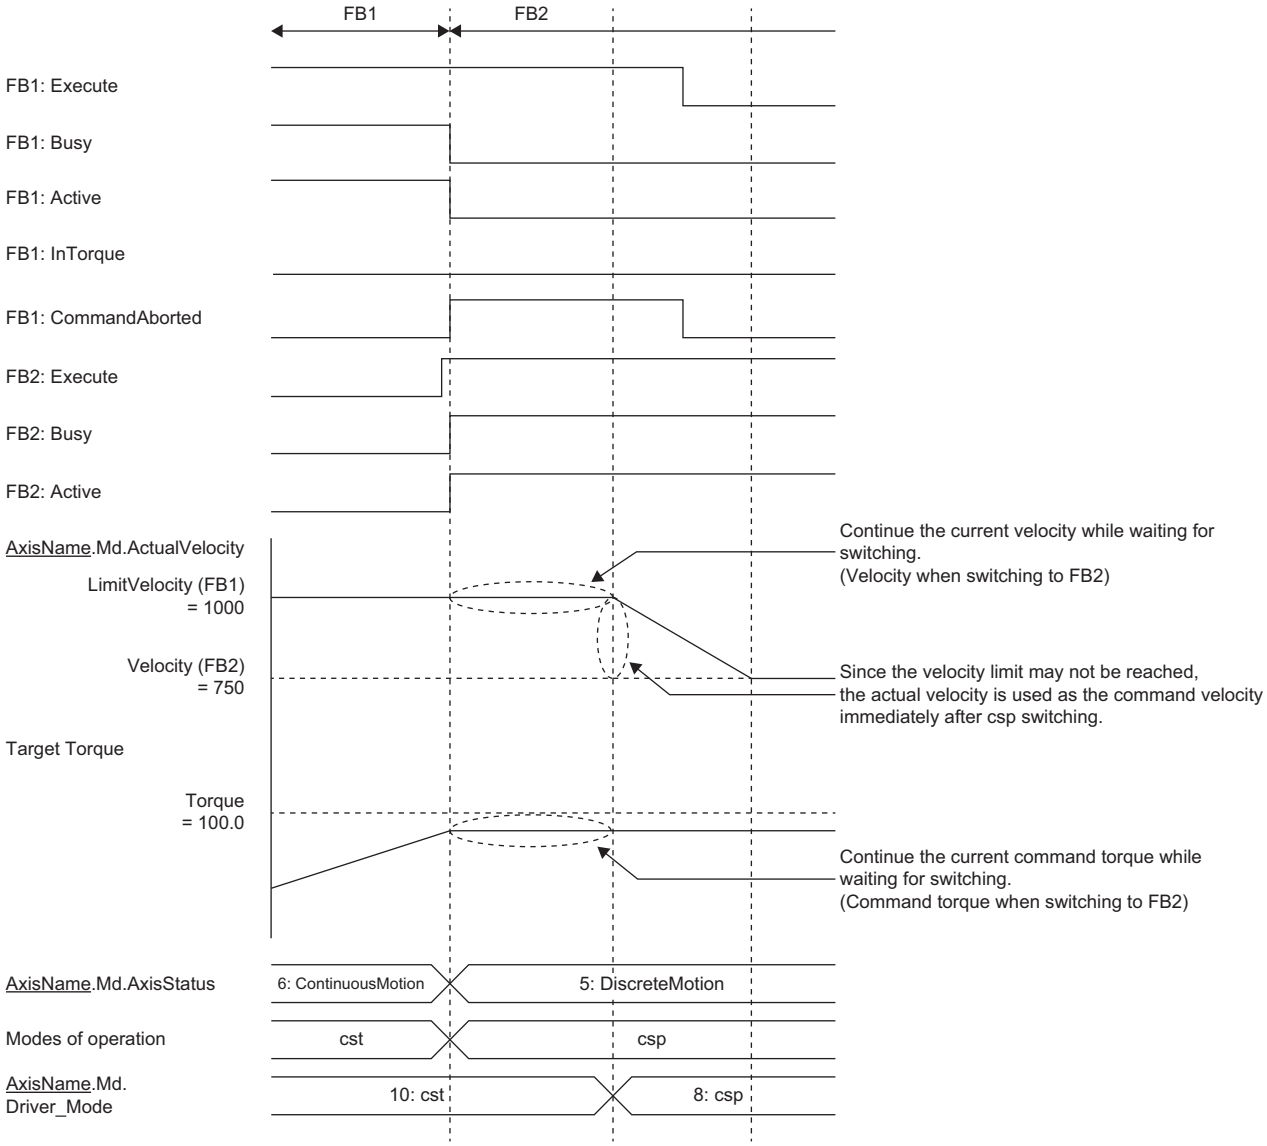
When starting another instruction during this FB execution

■Torque control → Stop instruction (MC_Stop (Forced Stop))

(1) MC_Stop (Forced Stop) is started.

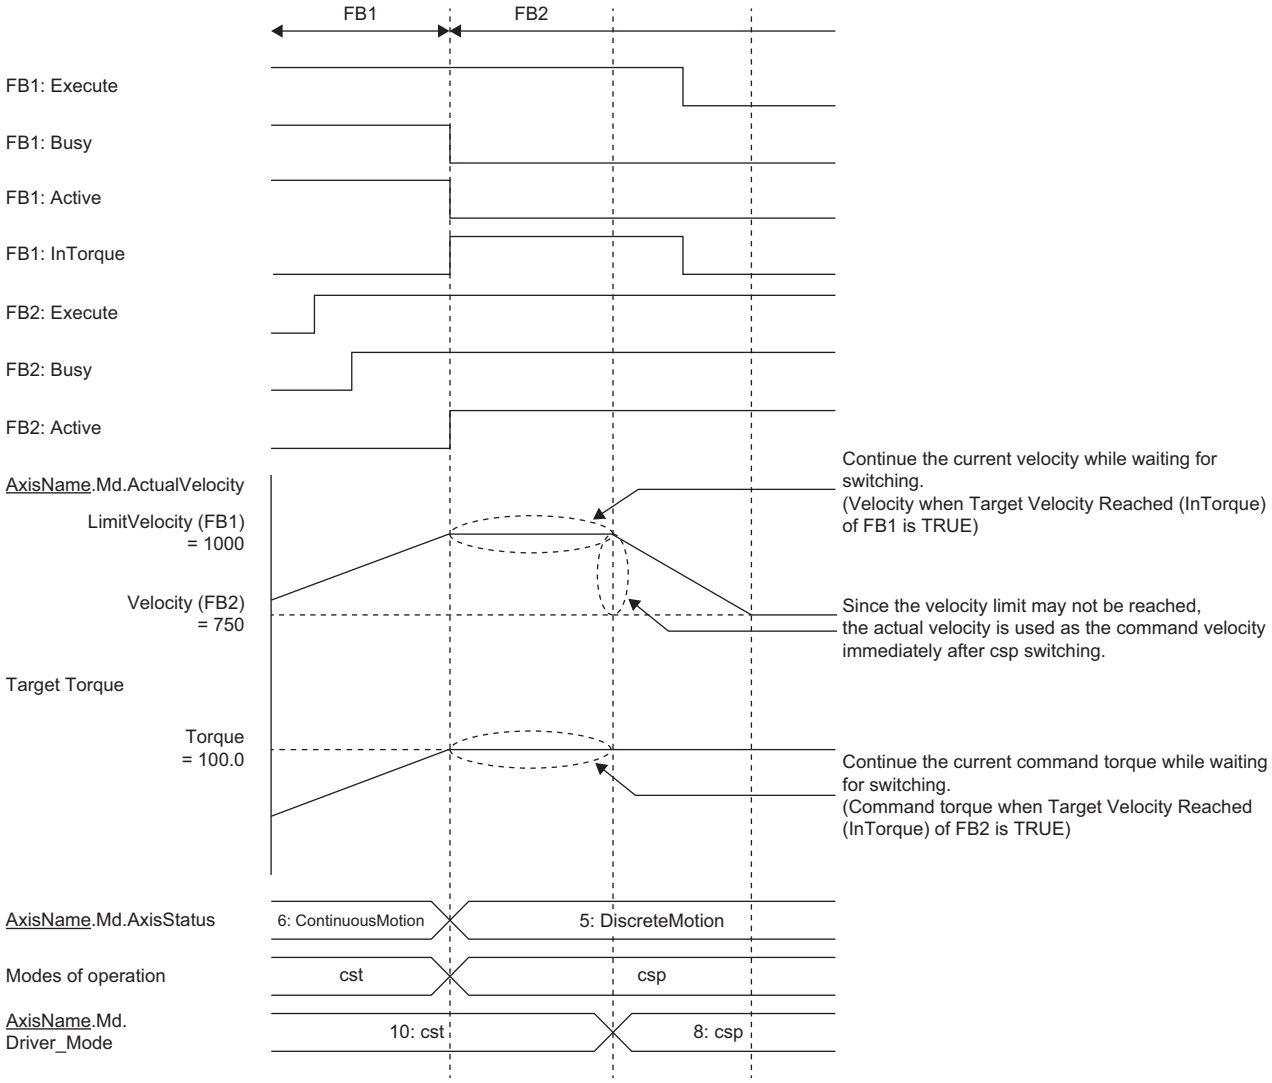
■Torque control → Positioning (Absolute value/Relative value positioning)

1. A switching request to the cyclic synchronous position mode (csp) is issued to the drive unit.
2. The positioning control FB that was started is analyzed, and the axis waits until the drive unit switches to the cyclic synchronous position mode (csp). (Even if a switching request to the cyclic synchronous position mode (csp) is executed during axis operation, switching may not be carried out depending on the drive unit specifications. If switching to the cyclic synchronous position mode (csp) is not completed within 1 [s], Control mode switching error (error code: 1A95H) occurs due to timeout and the axis stops.)
3. While waiting for switching, torque control is continued with the torque and the limit velocity at switching.
4. When the drive unit switches to the cyclic synchronous position mode (csp), the positioning control starts.



Point

- The deceleration distance may not be secured and the target position may be overrun depending on the travel distance switching from the cyclic synchronous torque mode (cst) to the cyclic synchronous position mode (csp). In this case, the axis operates based on Operation Setting at Overrun (AxisName.Pr.OverrunOperation). For the operation at the overrun occurrence, refer to the following.



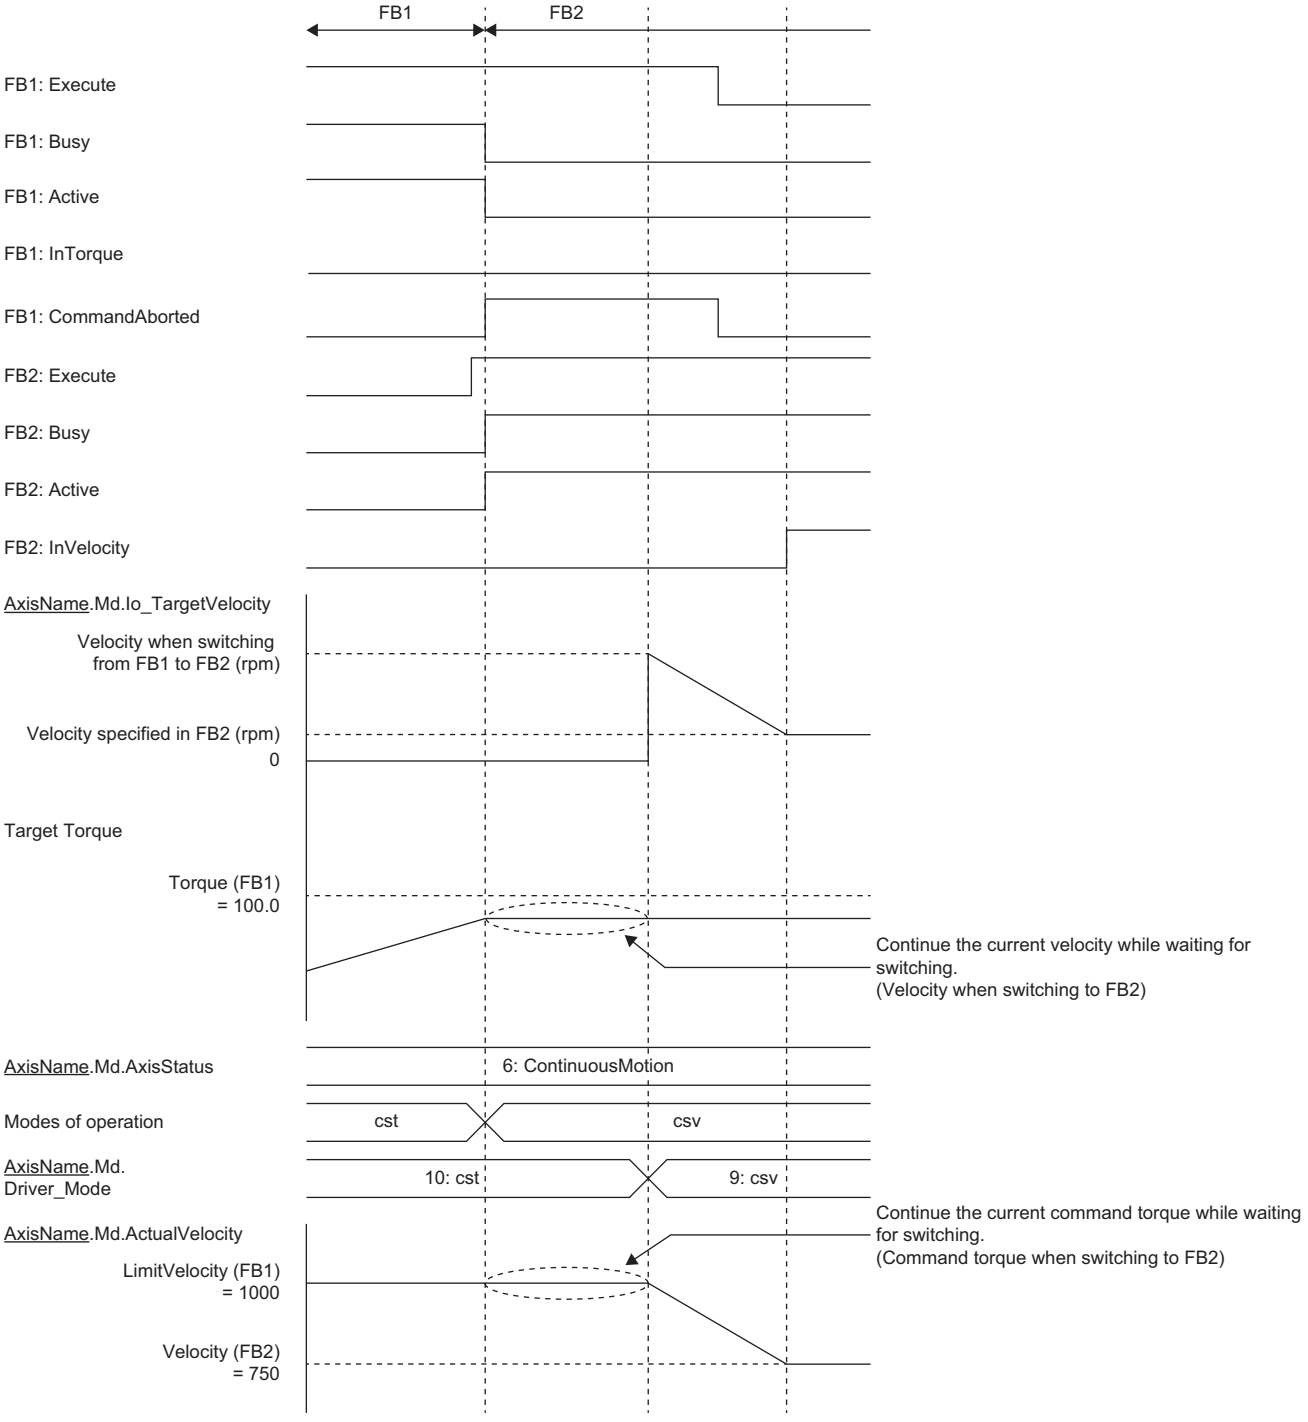
☞ Page 547 Multiple Start (Buffer Mode)

- If an overrun occurs while waiting for switching, Overrun error (error code: 1AE3H) will occur immediately after switching to the cyclic synchronous position mode (csp), and the motor will stop immediately, regardless of Operation Setting at Overrun (AxisName.Pr.OverrunOperation).

• 0: Aborting (mcAborting)

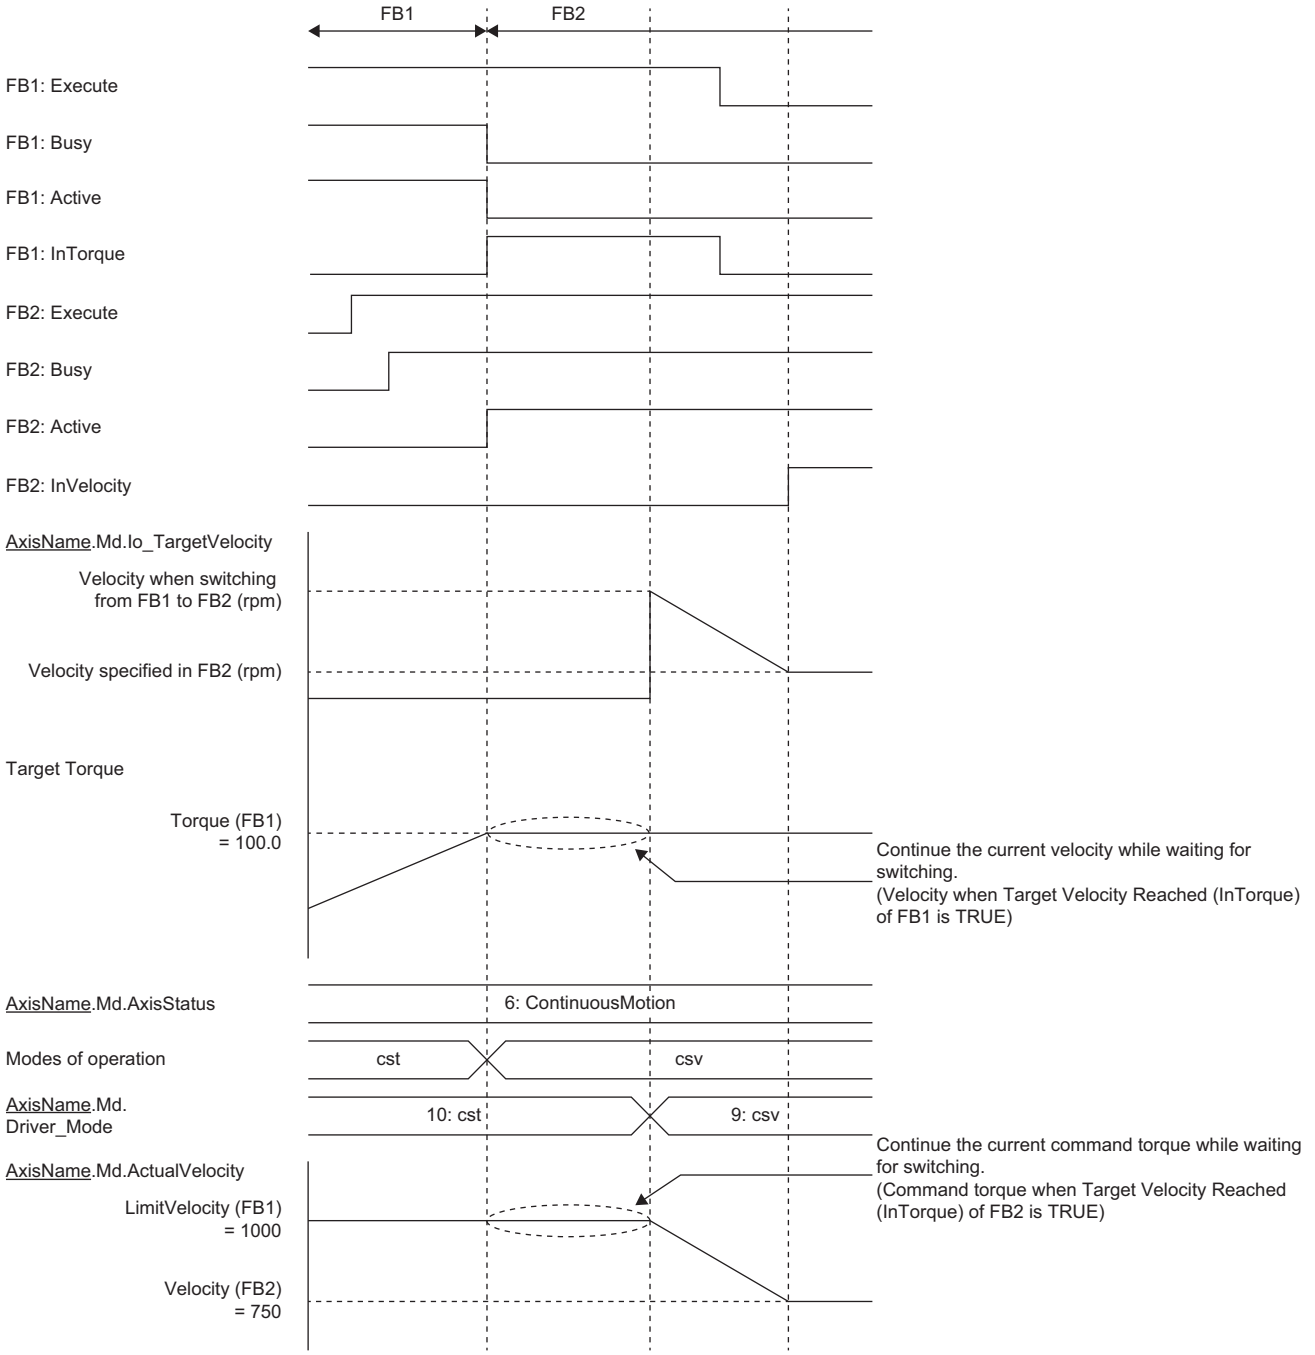
• 1: Buffered (mcBuffered)

■Torque control (FB1) → Velocity control (FB2)



1. A switching request to the cyclic synchronous velocity mode (csv) is issued to the drive unit.

2. The positioning control FB that was started is analyzed, and the axis waits until the drive unit switches to the cyclic synchronous velocity mode (csv). (Even if a switching request to the cyclic synchronous velocity mode (csv) is executed during axis operation, switching may not be carried out depending on the drive unit specifications. If switching to the cyclic synchronous velocity mode (csv) is not completed within 1 [s], Control mode switching error (error code: 1A95H) occurs due to timeout and the axis stops.)



3. While waiting for switching, torque control is continued with the torque and the limit velocity at switching.

4. When the drive unit switches to the cyclic synchronous velocity mode (csv), the velocity control starts.

• 0: Aborting (mcAborting)

• 1: Buffered (mcBuffered)

When the operation direction is reversed

When starting this FB and operation direction is reversed during another instruction execution, reverse the set torque according to the torque positive direction ramp and the torque negative direction ramp.

When starting an FB operated in the cyclic synchronous position mode (csp) and operation direction is reversed during this instruction execution, set velocity at the cyclic synchronous position mode (csp) switching is set to 0. After that, the operation starts in the changed direction.

Relevant object data

If no object data is set, PDO mapping is not performed, or no object exists in the device station, there will be errors and restrictions in the following functions.

For details on the object data settings, refer to the following.

☞ Page 466 Axis Assignment

◎: Required, ○: Recommended

Instruction/function	Required object data	PDO mapping	Operation with no object
MC_TorqueControl (Torque Control) (Control mode switching*1: cst)	Target torque	◎	Required object data unset (error code: 1AF7H) occurs.
	Velocity limit value	○	Velocity limit in cst cannot be set using LimitVelocity.
	Torque actual value	○	☞ Page 729 Torque initial value selection (Options (Options): bit 18)
MC_TorqueControl (Torque Control) (Control mode switching*1: ct)	Target torque	◎	Required object data unset (error code: 1AF7H) occurs.
	Velocity limit value	◎	Required object data unset (error code: 1AF7H) occurs.
	Torque actual value	○	☞ Page 729 Torque initial value selection (Options (Options): bit 18)
	Velocity actual value	○	☞ Page 715 Velocity initial value selection

*1 It can be set by control mode switching selection (Options bit19).

Precautions

- Velocity Override Factor (AxisName.Cd.VelocityOverride) and Acceleration Override Factor (AxisName.Cd.AccelerationOverride) are valid.
- The set position and the machine feed value are updated by follow up.
- Time until the control mode is switched depends on the specifications of the drive unit.
- When the stop cause occurs during the control mode switching, the axis will stop immediately.
- Do not start the positioning control FB during the control mode switching. Start the positioning control FB after checking that Driver Control Mode (AxisName.Md.Driver_Mode) is switched to "10: cst (Torque Control) (cst)".
- When switching the control mode from the cyclic synchronous position mode (csp) to cyclic synchronous velocity mode (csv), if a stop cause (axis error detection) occurs before the control mode is switched, follow-up may continue in cyclic synchronous position mode (csp) until the zero speed status is reached.
- When switching from the cyclic synchronous position mode (csp) to the cyclic synchronous torque mode (cst) or from the cyclic synchronous torque mode (cst) to the cyclic synchronous position mode (csp) without waiting for stop of the motor by using the MR-J5(W)-G, note the following.
  - Set the servo parameter (extension setting) "ZSP disabled selection at control switching (PC76.1)" to "1: Disabled" and disable monitoring of zero speed status. However, note that it may cause vibration or impact at control mode switching.
  - For the setting value of the servo parameter "Electronic gear numerator (PA06)" and "Electronic gear denominator (PA07)", refer to the following.
    ☞ Page 2152 Setting method
- When Velocity limit value is not mapped, the set torque is changed to 0 at stop cause occurrence.

Torque limit change during the cyclic synchronous torque mode (cst)

At restart or continuous update, if the target torque is changed to a value bigger than the torque limit value (Positive Direction Torque Limit Value (AxisName.Md.TorqueLimit_Positive), Negative Direction Torque Limit Value (AxisName.Md.TorqueLimit_Negative)), Torque Limit Value Over Warning (event code: 00D12H) occurs and the axis operates at the value before change.

During torque control, if Positive Direction Torque Limit Value (AxisName.Cd.TorqueLimit_Positive) and Negative Direction Torque Limit Value (AxisName.Cd.TorqueLimit_Negative) are changed to a value smaller than the target torque, the target torque will be changed to the torque limit value. In this case, the set torque is changed at one cycle.

29.4 Pressure Control

This control method switches the drive unit control mode to the cyclic synchronous pressure mode (cspr), and performs the control.
The pressure control compatible drive unit controls the pressure sensor (load cell) value.
The pressure ramp function and velocity limit acceleration/deceleration function adjust the slope of the command pressure and command limit velocity before sending them to the drive unit. Pressure control uses a drive unit that supports cyclic synchronous pressure mode (cspr). The following table lists the available drive unit and its firmware version.

Model name	Version
MR-J5-G-LL	"F0" or later

Restriction

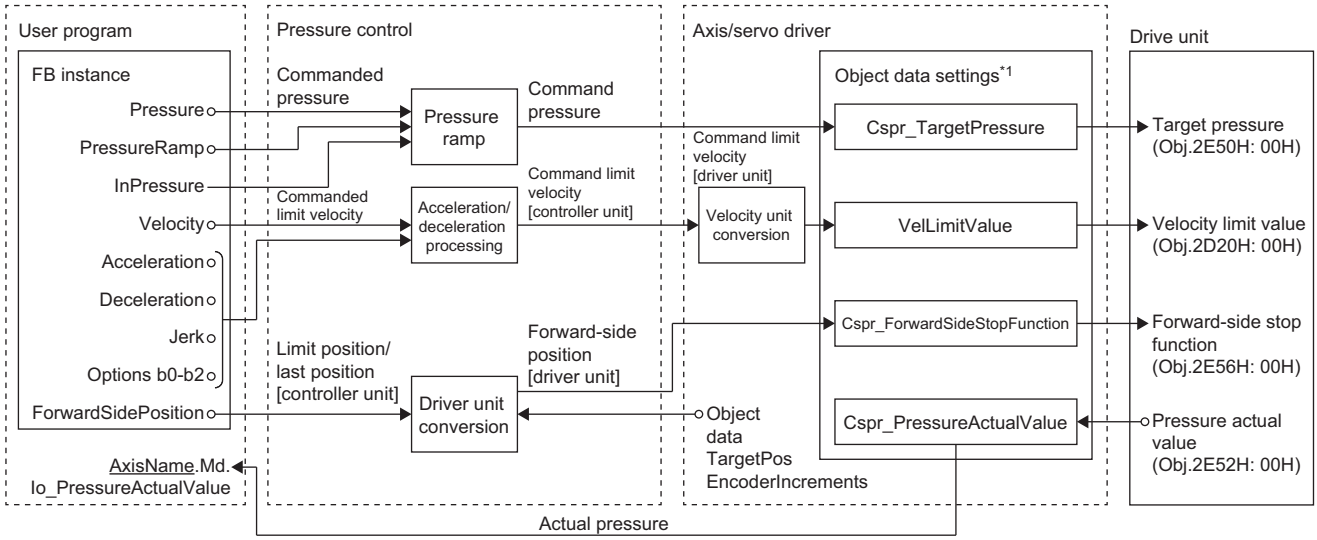
Before using this function, check the versions of the controller and engineering tool used. (☞ Page 2196 Added or Enhanced Functions and Supported Versions)

Relevant variable

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
ActualPosition	Actual Position	Stores the actual position (same as positioning control).
ActualVelocity	Actual Velocity	Stores the actual velocity (same as positioning control).
Cst_SetLimitVelocity	Set Limit Velocity at cst/ct/cspr	Stores the command limit velocity in the cyclic synchronous torque mode (cst), continuous operation to torque control mode (ct), and cyclic synchronous pressure mode (cspr).
Cspr_SetPressure	Set Pressure at cspr	Stores the command pressure in cyclic synchronous pressure mode (cspr).
Cspr_ForwardSidePosition	Forward-side Position at cspr	Stores the forward end position in cyclic synchronous pressure mode (cspr).
Io_PressureActualValue	Object Data_PressureActualValue	Displays the value of "Pressure actual value (2E52H)" in the object data.*1
TargetVelocity	Target Velocity	• Stores the actual velocity limit, taking override into account, in the limit velocity (LimitVelocity). The value becomes "0" or more regardless of the movement direction. • Stores "0" after the control is completed.
InVelocity	Target Velocity Reached	Stores FALSE (Not reached) when in cyclic synchronous pressure mode (cspr).

*1 For details on the object data, refer to the following.
☞ Page 472 Object data list



Relevant FB

For details on motion control FBs, refer to the following.
MELSEC MX Controller MX-R Model Programming Manual

Motion control FB	Name	Description
MCv_PressureControl	Pressure Control	Switches the drive unit control mode to cyclic synchronous pressure mode (cspr), and performs pressure control according to the specified pressure.

Overall block diagram

The relationship between pressure control and other functions is shown below.

*1 For the initial value of the real drive axis

Control details

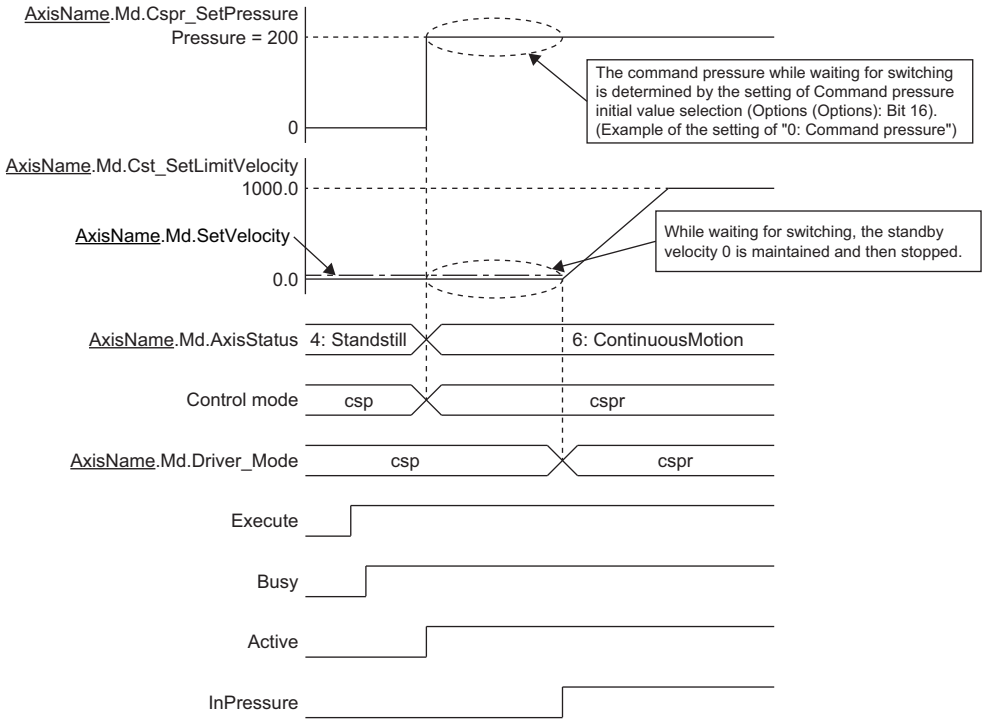
MCv_PressureControl (Pressure Control) is a function that switches the drive unit control mode to cyclic synchronous pressure mode (cspr) and performs pressure control.
To finish this FB, execute multiple start of MC_Stop (Forced Stop) or input an axis stop signal. Or, execute multiple start of another motion FB to switch to the cyclic synchronous position mode (csp).

Command pressure increase/decrease and servo motor movement direction

When using the MR-J5-G-LL, it differs according to the settings of the servo parameters "Selection of pressure increasing direction for positioning address (PW12.1)" and "Travel direction selection (PA14)".

- When "Selection of pressure increasing direction for positioning address (PW12.1)" is "0: The pressure increases as the positioning address decreases."

Setting value of Travel direction selection (PA14)	Command pressure	Servo motor movement direction
0: Positioning address increasing CCW rotation	Increase	Movement in the CW direction
	Decrease	Movement in the CCW direction
1: Positioning address increasing CW rotation	Increase	Movement in the CCW direction
	Decrease	Movement in the CW direction



- When "Selection of pressure increasing direction for positioning address (PW12.1)" is "1: The pressure increases as the positioning address increases."

Setting value of Travel direction selection (PA14)	Command pressure	Servo motor movement direction
0: Positioning address increasing CCW rotation	Increase	Movement in the CCW direction
	Decrease	Movement in the CW direction
1: Positioning address increasing CW rotation	Increase	Movement in the CW direction
	Decrease	Movement in the CCW direction

Driver control mode switching

This section describes the operation in which the driver control mode becomes cyclic synchronous pressure mode (cspr).

1. At startup, a control mode switching request to the cyclic synchronous pressure mode (cspr) is issued to the drive unit.
2. The standby velocity remains at "0" and the command position stops until the drive unit control mode is switched. Also, the command pressure will be Command pressure initial value selection (Options (Options): Bit 16), and the command limit velocity will be the initial value set in Command limit velocity initial value selection (Options (Options): bit 18, bit 19).
3. After the drive unit control mode is switched, the pressure ramp and acceleration/deceleration process will start from each set value.

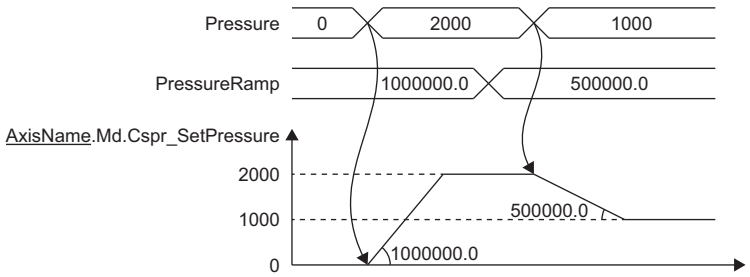
Operation at stop cause occurrence

The following shows stop causes during cyclic synchronous pressure mode (cspr) and the process when each cause occurs.

Cause number	Stop cause	Axis Status (AxisName.Md.AxisStatus)	Stop process
		After stop	
1	"Forced stop input" is off	1: Stopping on error (ErrorStop)	Immediate Stop*1
2	Drive unit power supply is off	1: Stopping on error (ErrorStop)	Immediate Stop*1
	Drive unit network disconnection detection		
	Drive unit error		
	Forced stop input to the drive unit		
	Enable (Enable) of MC_Power (Operation Available) is FALSE		
	Servo ON request (ServoON) of MC_Power (Operation Available) is FALSE (When Process Selection at Servo OFF Command During Operation (AxisName.Pr.StopMode_ServoOff) is "4: Servo OFF After Immediate Stop (ServoOffAfterImmediateStop)" or "5: Servo OFF After Deceleration to Stop (ServoOffAfterDecelStop)")*2		
	Drive unit control mode has switched to the control mode that is not supported by the motion system axis control.		
3	Hardware stroke limit upper/lower limit error occurrence	1: Stopping on error (ErrorStop)	The command limit velocity is changed to 0, and an immediate stop is performed.*5 After stopping, the control mode switches to the cyclic synchronous position mode (csp).
4	Occurrence of a moderate or major error of the controller	1: Stopping on error (ErrorStop)	
	PLC READY is off.		
	Motion system moderate or major error occurrence		
	Cycle over error occurrence		
5	Software stroke limit upper/lower limit error occurrence	1: Stopping on error (ErrorStop)	
6	Axis error detection*3	1: Stopping on error (ErrorStop)	
7	Execution command (Execute) of MC_Stop (Forced Stop) is TRUE	2: Decelerating to stop (Stopping)*4	The command limit velocity is changed to 0, and an immediate stop is performed.*5 After stopping, the control mode switches to the cyclic synchronous position mode (csp). (Not based on the deceleration of MC_Stop (Forced Stop))
8	"Stop signal (STOP)" of external input signal is TRUE	4: Standby (Standstill)	The command limit velocity is changed to 0, and an immediate stop is performed.*5 After stopping, the control mode switches to the cyclic synchronous position mode (csp).

*1 The servo turns off on the drive unit side and an immediate stop is performed, and also the motion system side command is stopped.

*2 Operation differs depending on the setting value selected in Process Selection at Servo OFF Command During Operation (AxisName.Pr.StopMode_ServoOff). For details, refer to the following.
☞ Page 579 Relevant variables



*3 If an axis error (the error that transits the status into the "1: Stopping on error (ErrorStop)" status) occurs in the buffering FB, immediate stop will be performed upon the occurrence of the error.

*4 When Execution command (Execute) of MC_Stop (Forced Stop) is FALSE at stop completion, Axis Status (AxisName.Md.AxisStatus) after stop will be "4: Standby (Standstill)".

*5 The command pressure value is not changed. Note that it may take some time for the velocity to reach 0 depending on the command pressure when a stop cause occurs.

Pressure ramp function

- This function adjusts the slope of the command pressure to be sent to the drive unit.
- The command pressure is generated based on the pressure (Pressure) and pressure ramp (PressureRamp).

- If the generated result is not an integer, the value with the decimal portion truncated is used as the command pressure.
- If the pressure ramp (PressureRamp) is set to "0.0", the specified pressure is reached within one control cycle.
- When the control mode is switched from the cyclic synchronous position mode (csp) to the cyclic synchronous pressure mode (cspr) at startup or multiple start, the command pressure set in Command pressure initial value selection (Options (Options): Bit 16) will be used as the initial value for operation. For details on startup and multiple start, refer to the following.

☞ Page 745 Driver control mode switching

Command pressure initial value selection (Options (Options): Bit 16)

Set the initial value of the command pressure when the control mode is switched from the cyclic synchronous position mode (csp) to the cyclic synchronous pressure mode (cspr).

Setting value	Description
0: Specified pressure	The initial value of the command pressure is the pressure (Pressure).
1: Feedback pressure	The initial value of the command pressure is the feedback pressure (Object data _PressureActualValue(AxisName.Md.Io_PressureActualValue)). If the feedback pressure is a negative value, it will be set to "0". Also, if the value exceeds "30000", it will be set to "30000".*1

*1 When the object assigned to object data "Pressure actual value (2E52H)" is not PDO mapped, it will not be used as the feedback pressure. (The initial pressure value is "0".)

Precautions

- The time (pressure ramp time) required for the command pressure to reach the pressure (Pressure) is limited to 8400 [s]. The pressure ramp time calculated from the pressure (Pressure), the pressure ramp (PressureRamp), and the command pressure is limited. Set the pressure (Pressure) and the pressure ramp (PressureRamp) so that the pressure ramp time does not exceed 8400 [s].
- The pressure ramp time is calculated as follows.

Type	Item	Abbreviation	Description	Calculation formula
Specified value	Pressure (Pressure)	P	Sets the specified pressure.	—
	Pressure ramp (PressureRamp)	PR	Sets the ramp (slope) for reaching the pressure (Pressure) from the command pressure.	
Command current value	Command pressure	Pnow	Current pressure command value	
Calculated value	Pressure ramp time	—	Time to reach the pressure (Pressure) from the command pressure	| P - Pnow | ÷ PR

- At startup or when switching between FBs due to executing multiple start, if the command pressure has not yet reached the pressure (Pressure) and the pressure ramp time exceeds 8400 [s], Ramp time over (error code: 1B3FH) will occur.
- When the pressure (Pressure) or pressure ramp (PressureRamp) is changed during a restart/continuous update, if the command pressure has not yet reached the pressure (Pressure) and the pressure ramp time exceeds 8400 [s], the changed value will be ignored, and the operation will continue with the previous value. When changing the setting, Ramp Time Over Warning (event code: 00D53H) will occur.

Velocity limit acceleration/deceleration processing function

- Adjusts the slope of the command limit velocity to be sent to the drive unit.
- The command limit velocity is generated based on the limit velocity (LimitVelocity), acceleration (Acceleration), deceleration (Deceleration), and acceleration/deceleration method setting (Options (Options) bits 0 to 2). For details, refer to the following. (However, the variable velocity (Velocity) is to be interpreted as the limit velocity (LimitVelocity)).
  ☞ Page 1078 Acceleration/Deceleration Processing Function
- When the control mode is switched from the cyclic synchronous position mode (csp) to the cyclic synchronous pressure mode (cspr) at startup or multiple start, the command limit velocity set in Command limit velocity initial value selection (Options (Options): bit 18, bit 19) operates from the initial value. For details on startup and multiple start, refer to the following.
  ☞ Page 745 Driver control mode switching

Command limit velocity initial value selection (Options (Options): bit 18, bit 19)

Set the initial value of the command limit velocity when the control mode is switched from the cyclic synchronous position mode (csp) to the cyclic synchronous pressure mode (cspr).

Setting value	Description
0: Command velocity	The initial value of the command limit velocity is the absolute value of Set Velocity (AxisName.Md.SetVelocity). After switching, acceleration and deceleration occur toward the limit velocity (LimitVelocity).
1: Specified limit velocity	The command limit velocity initial value is the limit velocity (LimitVelocity).
2: Automatic selection	The command limit velocity initial value is the lower of "0: Command velocity" and "1: Commanded velocity". If "0: Command velocity" is lower, after switching, acceleration and deceleration occur toward the limit velocity (LimitVelocity).

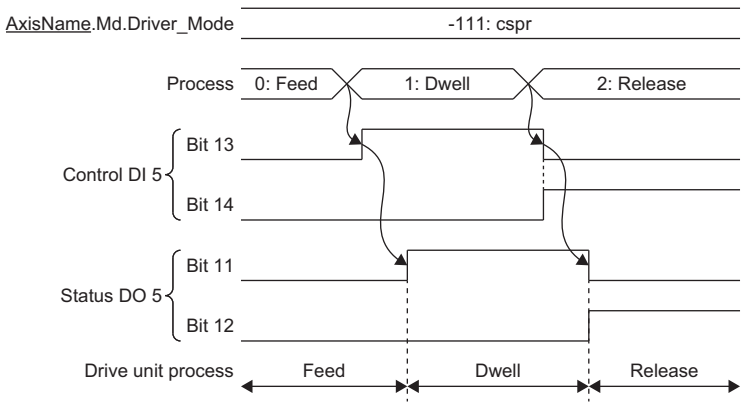
When switching from the cyclic synchronous position mode (csp) to the cyclic synchronous pressure mode (cspr) during axis movement, vibration or impact at the time of switching can be suppressed using the command limit velocity, by setting Command limit velocity initial value selection (Options (Options): bit 18, bit 19) and the limit velocity (LimitVelocity) as follows.

- Set Command limit velocity initial value selection (Options (Options): bit 18, bit 19) to "0: Command velocity".
- Set the limit velocity (LimitVelocity) to a value equal to or lower than the command velocity at the time of switching, and set Command limit velocity initial value selection to "1: Commanded limit velocity".

Precautions

- The command limit velocity and its acceleration/deceleration override function are enabled. For details on the override function, refer to the following. (However, "target velocity" is to be interpreted as "command limit velocity".)
  ☞ Page 1116 Override Function
- If multiple start was executed by specifying "0" for acceleration (Acceleration) or deceleration (Deceleration), the target acceleration or target deceleration of the previous FB will not be inherited. The operation is the same as when starting up.

Pressure control process



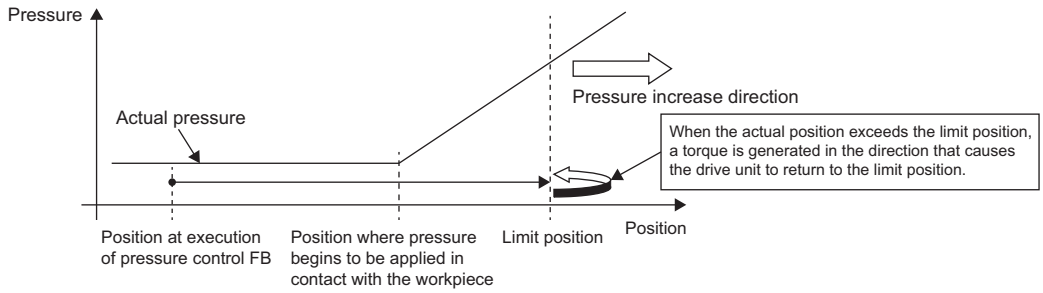
- Pressure control involves the feeding, pressure-holding, and pressure-release processes. Use MCv_PressureControl (Pressure Control) to create a user program that performs the following in each process.

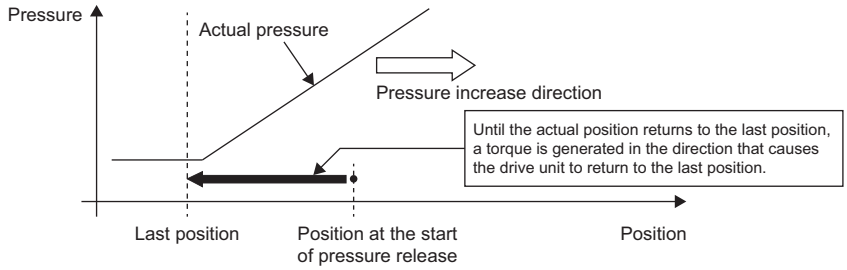
Pressure control process (Process)	Process description	Process operation procedure
0: Feeding (Feed)	The process of bringing the tip of the machine that applies pressure into contact with the workpiece and gradually moving it to the pressure-holding start position	1. The tip of the machine approaches the workpiece at a low velocity. 2. The tip of the machine contacts the workpiece. After contact, the load cell pressure (feedback pressure) begins to increase. 3. Specify the velocity limit and pressure, and gradually move to the pressure-holding start position. 4. Switch to pressure holding.
1: Pressure holding (Dwell)	The process of applying pressure to the workpiece	5. Set the pressure and apply various levels of pressure to the workpiece. <Example> Light pressure → Strong pressure → Medium pressure
2: Pressure release (Release)	The process of releasing pressure applied to the workpiece	6. Set the pressure or the final position to reduce the pressure applied to the workpiece. This reduces the feedback pressure. 7. Once the feedback pressure has sufficiently decreased, end the pressure-release process.

- Set the pressure control process (Process) to send the pressure control process to the drive unit. When using the MR-J5-G-LL, the servo parameter "Pressure model adaptive control selection (PW34.0)" is used to enable or disable the pressure model adaptive control during pressure holding or pressure release.

Pressure model adaptive control selection (PW34.0) setting value	Pressure control process	
	Pressure holding	Pressure release
0	Disable	Disable
1	Enable	
2	Disable	Enable
3	Enable	

- When the servo parameter "Pressure model adaptive control selection (PW34.0)" is set to a value other than "0" and pressure model adaptive control is enabled for pressure holding or pressure release, set the pressure control process (Process) according to the content to be executed in the user program. If the pressure model adaptive control is not enabled, the pressure control process (Process) remains at its initial value (0: Feed), and no further settings are required. For details on the pressure model adaptive control, refer to the manuals for the MR-J5-G.
- To send to the drive unit, use "Bit 13 (C_ATHO): Pressure control Dwelling command" and "Bit 14 (C_ATRE): Pressure control Depressurization command" of "Control DI 5 (2D05H)" in the object data. To check the drive unit process, monitor "Bit 11 (S_ATHO): Pressure control Dwelling in progress" and "Bit 12 (S_ATRE): Pressure control Depressurization in progress" in "Status DO 5 (2D15H)" of the network-labeled object data.





Precautions

- If the feedback velocity at the start of feeding has not reached the limit velocity, increase the command pressure at the start of feeding. (The command pressure at the start of pressure holding does not need to be changed.)
- If the feedback pressure overshoots during the switch from feeding to pressure holding, set the acceleration (Acceleration) and deceleration (Deceleration) so that the acceleration/deceleration at the start of pressure holding is reduced.

Limit position / final position (forward end position)

By setting the forward end position (ForwardSidePosition), the following operations occur for each pressure control process.

Pressure control process	Operation
Feeding / pressure holding	Limit the range of movement in the direction of increasing pressure. Set the range limit position at the forward end position (ForwardSidePosition). 
Pressure release	Specify the final position where the feedback pressure decreases, and perform the pressure-release operation. Set the final position at the forward end position (ForwardSidePosition). 

- MCv_PressureControl (pressure control) converts the forward end position (ForwardSidePosition) into driver units and generates the forward end position to be sent to the drive unit. To send to the drive unit, use the object data "Forward-side stop function (2E56H)".
- During cspr, Forward End Position (AxisName.Md.Cspr_ForwardSidePosition) can be used to check the forward end position sent to the drive unit in position command units.
- Regardless of the pressure control process, if the current position exceeds the limit position/final position (forward end position) in the direction of increasing pressure, the drive unit's forward end stop function generates torque in the direction of returning to the forward end position.

Precautions

- There are restrictions on the effective range of the forward end position (ForwardSidePosition) and the movement range during control. Use them within the restricted range. The upper limit of the range is shown below.

Upper limit of the range
(2147483648[*1] - 10 × Encoder resolution [*2] / Electronic gear[*3]) × Driver unit conversion denominator / Driver unit conversion numerator

*1 "2147483648" = "2^{31}"
*2 Encoder resolution obtained from the drive unit (object data "Encoder increments (608FH)")
*3 This electronic gear (Gear ratio) is obtained from the drive unit. When using the MR-J5-G-LL, this value reflects the settings of the servo parameter "Electronic gear numerator (PA06)" and "Electronic gear denominator (PA07)".

■Effective range of the forward end position (ForwardSidePosition)

Restriction	Timing	Processing when out of range
Set Position (AxisName.Md.SetPosition) at the time of the control mode switching request[*1] to the cyclic synchronous pressure mode (cspr) is set as the reference position, and the forward end position (ForwardSidePosition) is set within the range where the absolute value of the difference from the reference position does not exceed the upper limit.	When control begins	Forward End Position Incorrect (error code: 1B3EH) occurs.
Set Position (AxisName.Md.SetPosition) at the time of the control mode switching request[*1] to the cyclic synchronous pressure mode (cspr) is set as the reference position, and the forward end position (ForwardSidePosition) is changed within the range where the absolute value of the difference from the reference position does not exceed the upper limit.	When control changes	The changed value will be ignored and the operation will continue with the previous value. When the change is made, Forward End Position Incorrect Warning (event code: 00D51H) occurs.
During cspr, the forward end position (ForwardSidePosition) is changed within the range where the absolute value of the difference from Forward End Position (AxisName.Md.Cspr_ForwardSidePosition) does not exceed the upper limit.		

*1 If the pressure control FB is called from a program with the same cycle as the axis control cycle, its behavior is the same as at rising during control (Active).

■Movement range during control

Restriction	Timing	Processing when out of range
The absolute value of the difference between Set Position (AxisName.Md.SetPosition) and Forward End Position (AxisName.Md.Cspr_ForwardSidePosition) during cspr is used within the range that does not exceed the upper limit.	During control	Forward end position error (error code: 1B40H) occurs.

- By setting the electronic gear and driver unit conversion so that the encoder resolution of driver units is reduced, it is possible to expand the effective range of the forward end position (ForwardSidePosition) and the movement range during control. For details on the electronic gear setting of the drive unit, refer to the following.
☞ Page 2152 MR-J5(W)-G (cyclic synchronous mode) connection method

Ex.

When performing pressure control using the MR-J5-G-LL and a rotary servo motor

In settings A and B, the relationship between the units of the motion system and the servo motor end is the same.

If the range of restrictions is a problem with setting A, changing to setting B can expand the range while maintaining the relationship between the units of the motion system and the servo motor end.

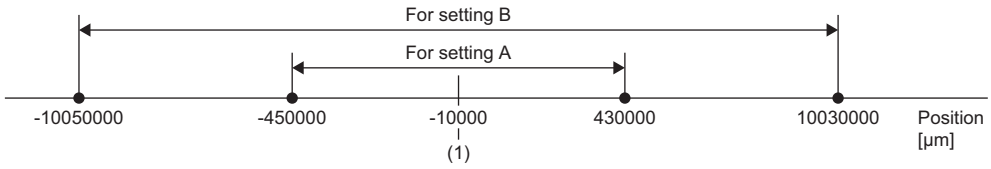
■Setting

- Motion system

Setting item	Setting value	
	Setting A	Setting B
Position Command Unit (AxisName.Pr.Unit_Position)	HFA010000 (μm)	
Driver Unit Conversion Numerator (AxisName.Pr.Drive_UnitConvRatioNum)	67108864 [pulse]	4194304 [pulse]
Driver Unit Conversion Denominator (AxisName.Pr.Drive_UnitConvRatioDen)	20000 [μm]	

- MR-J5-G-LL

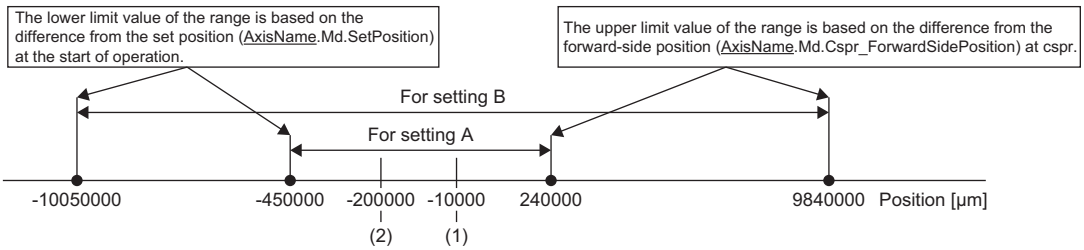
Setting item	Setting value	
	Setting A	Setting B
Electronic gear numerator (PA06)	1	16
Electronic gear denominator (PA07)	1	
Motor encoder resolution	67108864 [pulse/rev]	



■Upper limit of the range

$(2^{31}$ - 10 × Encoder resolution / Electronic gear) × Driver unit conversion denominator / Driver unit conversion numerator

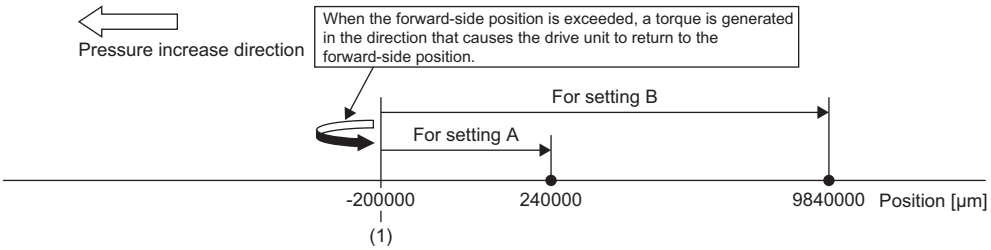
$=(2^{31}$ - 10 × Encoder resolution / (Electronic gear numerator (PA06) / Electronic gear denominator (PA07))) × Driver unit conversion denominator / Driver unit conversion numerator



Setting	Upper limit of the range
Setting A	(2147483648 - 10 × 67108864 / (1 / 1)) × 20000 / 67108864 = 440000[μm]
Setting B	(2147483648 - 10 × 67108864 / (16 / 1)) × 20000 / 4194304 = 10040000[μm]

- When the pressure control FB is started with Set Position (AxisName.Md.SetPosition) set to "-10000 [μm]", the effective range of "Forward-side position at start (ForwardSidePosition)" is as follows.

(1) Set Position (AxisName.Md.SetPosition) at startup



• If the pressure control FB is started with Set Position (AxisName.Md.SetPosition) set to "-10000[μm]", and Forward End Position (AxisName.Md.Cspr_ForwardSidePosition) during cspr is "-200000[μm]", the effective range of the forward end position (ForwardSidePosition) when control is changed is as follows.

(1) Set Position (AxisName.Md.SetPosition) at startup

(2) Forward End Position (AxisName.Md.Cspr_ForwardSidePosition) during cspr

• When Forward End Position (AxisName.Md.Cspr_ForwardSidePosition) during cspr is "-200000[μm]", the movement range during control of the pressure control FB is as follows.

(1) Forward End Position (AxisName.Md.Cspr_ForwardSidePosition) during cspr

• To enable the limit position/final position, perform PDO mapping on the object assigned to the object data "Forward-side stop function (2E56H)". If PDO mapping is not performed, the forward end position (ForwardSidePosition) setting will be ignored and the limit position/final position will be disabled.
When using the MR-J5-G-LL, the following PDO mapping and servo parameter settings are recommended.

Limit position/final position	Setting of PDO mapping of the object assigned to the object data "Forward-side stop function (2E56H)"	Setting of the servo parameter "Forward/reverse-side stop function (PW12.2)"
Enable	Perform PDO mapping.	1h (Forward-end stop: Enabled, Backward-end stop: Disabled)
Disable*1	Do not perform PDO mapping.*2	2h (Forward-end stop: Disabled, Backward-end stop: Disabled)

*1 The forward end stop function is disabled. To limit the range of movement in the direction of increasing pressure, set the software stroke limit.

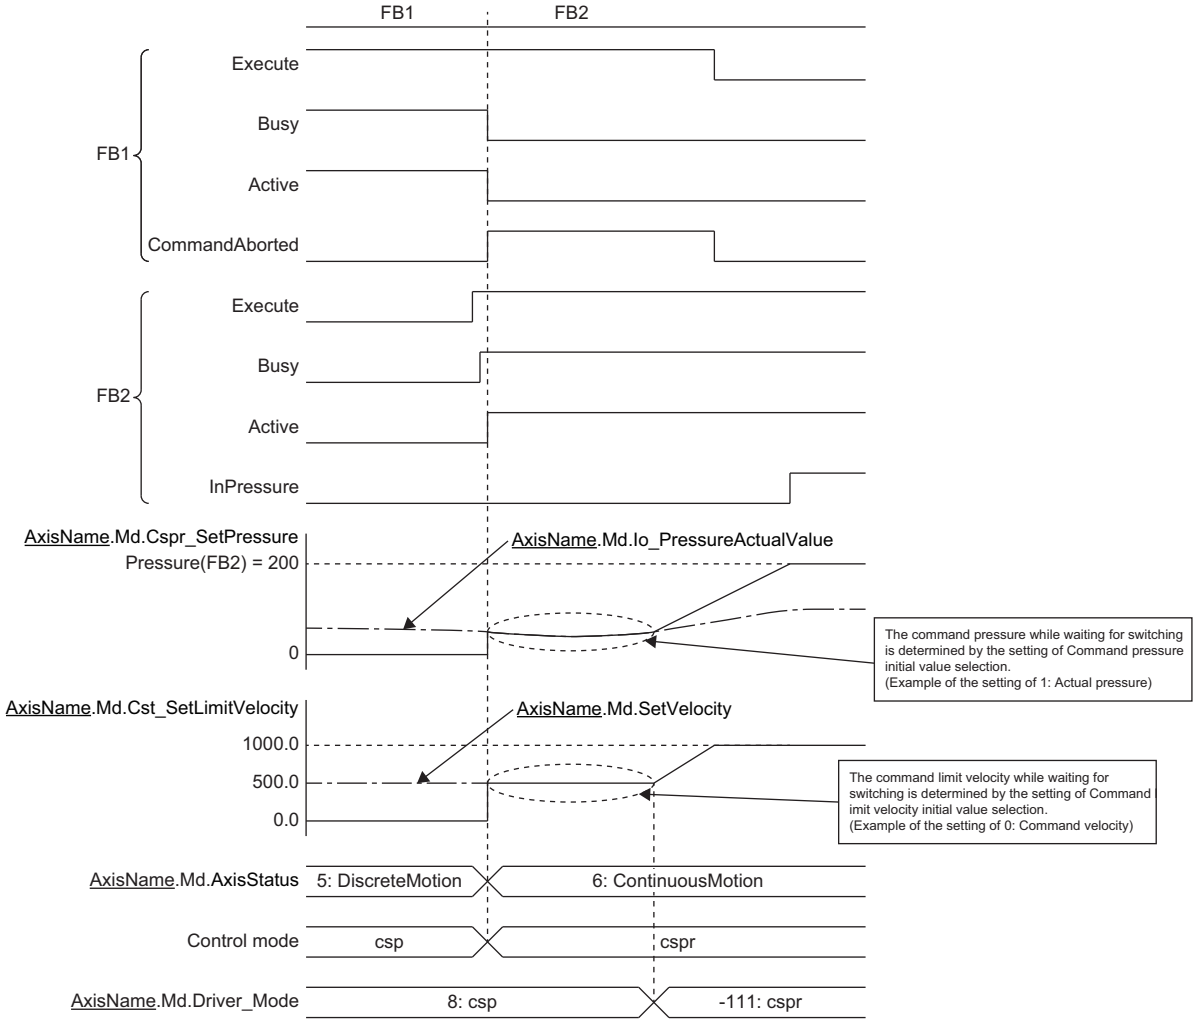
*2 Either set the "Forward-side stop function (2E56H)" not to be PDO mapped, or set the object data (AxisName.PrConst.SlaveObject.vCspr_ForwardSideStopFunction) to "" (string of length 0).

• When performing pressure control with the limit position/final position enabled, enable the software stroke limit function. If the software stroke limit function is disabled, executing the FB will result in Start when software stroke limit is disabled (error code: 1B3DH).

Multiple start (buffer mode)

When multiple start was executed for the pressure control FB while a previous motion FB is still in control

■Cyclic synchronous position mode (csp) → Cyclic synchronous pressure mode (cspr)



1. When switching FBs due to multiple start, a control mode switching request to the cyclic synchronous pressure mode (cspr) is issued to the drive unit.

2. Position control continues at the velocity of the previous motion FB until the drive unit control mode is switched. Also, the command pressure and command limit velocity will be set to their initial values[*1].

*1 The initial values of the command pressure and command limit velocity are set as follows.
· Command pressure initial value selection (Options (Options): bit 16)
· Command limit velocity initial value selection (Options (Options): bit 18, bit 19)

3. After the drive unit control mode is switched, the pressure ramp and acceleration/deceleration process will start from each set value.

• For 0: Aborting (mcAborting)

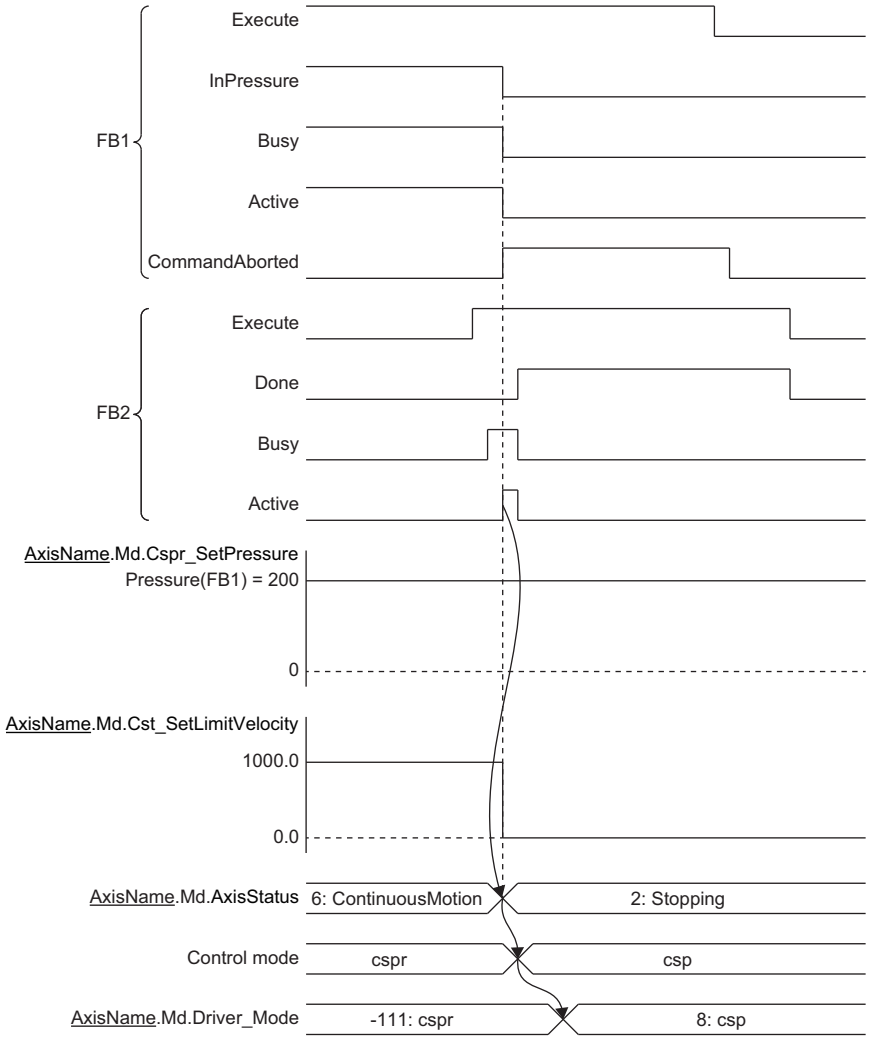
■If the previous motion FB is a pressure control FB

If the previous motion FB is a pressure control FB, refer to the following.

☞ Page 757 When multiple start was executed for another pressure control FB while the pressure control FB is still in control

When multiple start was executed for the next motion FB while the pressure control FB is still in control

■Cyclic synchronous pressure mode (cspr) → Cyclic synchronous position mode (csp)

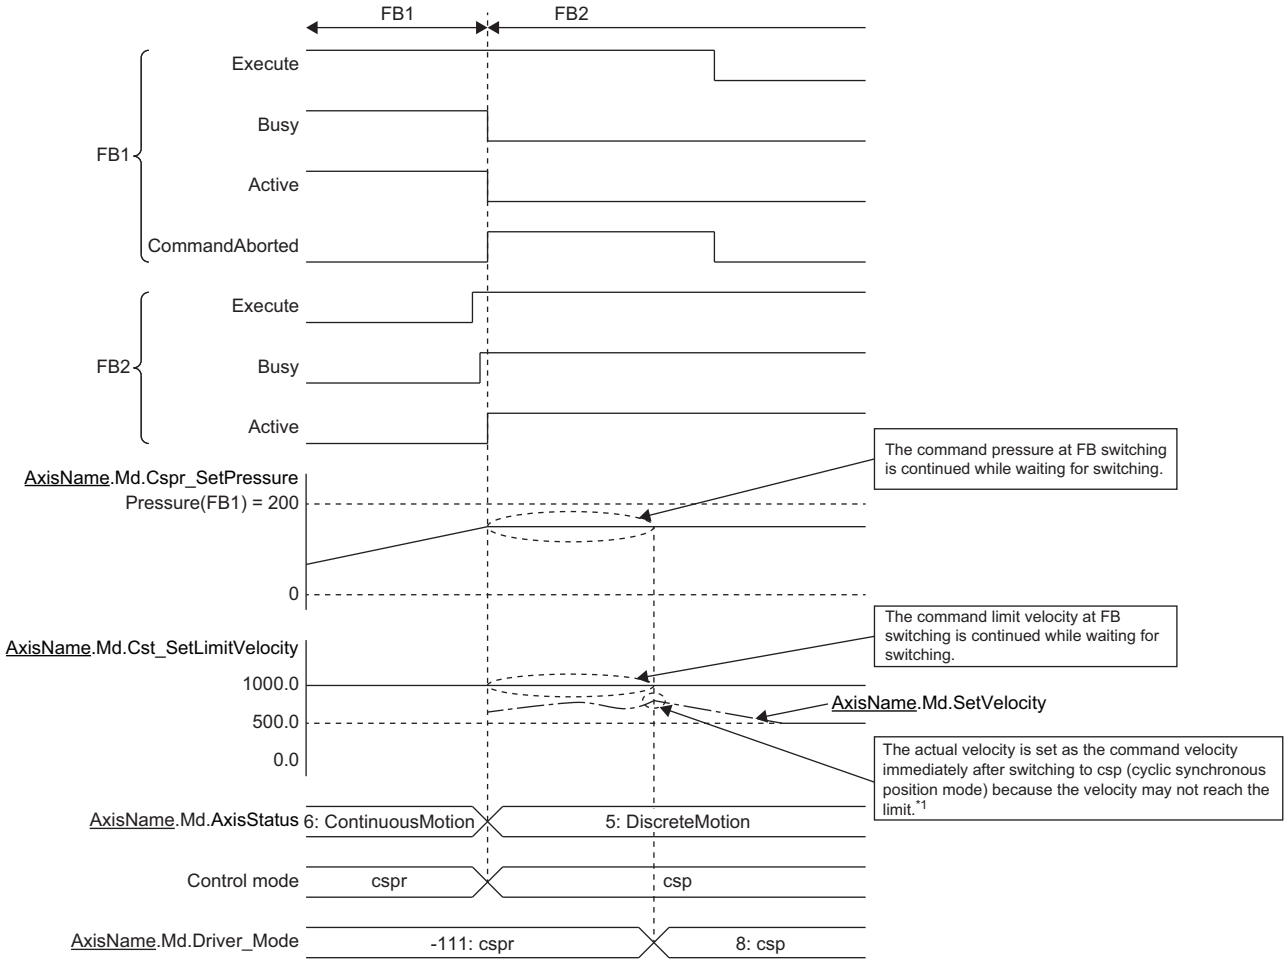


- When the next motion FB is MC_Stop (Forced Stop)

1. When switching FBs due to multiple start, a control mode switching request to the cyclic synchronous position mode (csp) is issued to the drive unit. Also, the command limit velocity is set to "0".

2. Until the drive unit control mode is switched, pressure control continues with the command limit velocity set to "0" and with the command pressure set at the time the request was issued.

3. Once the drive unit control mode has been switched, MC_Stop (Forced Stop) is complete.



- MC_Stop (Forced Stop) 0: Aborting (mcAborting)

• When the next motion FB is not MC_Stop (Forced Stop)

1. When switching FBs due to multiple start, a control mode switching request to the cyclic synchronous position mode (csp) is issued to the drive unit.
2. Until the drive unit control mode is switched, pressure control continues with the command pressure and command limit velocity at the time the request was issued.
3. Once the drive unit control mode is switched, position control begins.

• Positioning control FB 0: Aborting (mcAborting)

*1 When the operation direction differs between the pressure control FB and the next motion FB, the set velocity immediately after switching to the cyclic synchronous position mode (csp) is set to "0". After that, position control starts in the direction of the next motion FB.

Point

When the next motion FB is a positioning control FB, depending on the distance moved before the control mode of the drive unit is switched, the deceleration distance may not be secured and the target position may be overrun. In this case, immediately after switching to the cyclic synchronous position mode (csp), the axis operates based on Operation Setting at Overrun (AxisName.Pr.OverrunOperation). For the operation at the overrun occurrence, refer to the following.

☞ Page 547 Multiple Start (Buffer Mode)

However, if overrun occurs while waiting for switching, regardless of Operation Setting at Overrun (AxisName.Pr.OverrunOperation), Overrun error (error code: 1AE3H) will occur immediately after switching to the cyclic synchronous position mode (csp), and the axis will stop immediately.

■When the next motion FB is a pressure control FB

When the next motion FB is a pressure control FB, refer to the following.

☞ Page 757 When multiple start was executed for another pressure control FB while the pressure control FB is still in control

When multiple start was executed for another pressure control FB while the pressure control FB is still in control

Do not execute multiple start of another pressure control FB while the pressure control FB is still in control.
Otherwise, BufferMode specification disabled (error code: 1AE5H) will occur.

Precautions

- Follow-up is performed during the cyclic synchronous pressure mode (cspr). For details on follow-up, refer to the following.
  ☞ Page 504 Follow Up
- Time until the control mode is switched depends on the specifications of the drive unit.
- Do not execute multiple start of the positioning control FB until the control mode is switched from the cyclic synchronous position mode (csp) to the cyclic synchronous pressure mode (cspr). Execute multiple start of the positioning control FB after checking that Driver Control Mode (AxisName.Md.Driver_Mode) is switched to "-111: Cyclic synchronous pressure mode (cspr)".
- An actual motor velocity may not reach the limit velocity depending on the machine load during the cyclic synchronous pressure mode (cspr).
- When switching the control mode from the cyclic synchronous position mode (csp) to the cyclic synchronous pressure mode (cspr), or from the cyclic synchronous pressure mode (cspr) to the cyclic synchronous position mode (csp), it is recommended to switch after changing the motor to stop status (zero speed status). The zero speed status can be monitored by network labeling Status DO2 (2D12H).
- When switching the control mode from the cyclic synchronous position mode (csp) to the cyclic synchronous pressure mode (cspr), if a stop cause (axis error detection) occurs before the control mode is switched, follow-up may continue in the cyclic synchronous position mode (csp) until the zero speed status is reached.
- When switching from the cyclic synchronous position mode (csp) to the cyclic synchronous pressure mode (cspr), or from the cyclic synchronous pressure mode (cspr) to the cyclic synchronous position mode (csp), without waiting for the motor to stop, set "ZSP disabled selection at control switching (PC76.1)" of the servo parameter to "1: Disabled" and disable monitoring of the zero speed status. However, note that it may cause vibration or impact at control mode switching.
- During the cyclic synchronous pressure mode (cspr), driver command discard detection is not performed regardless of Driver Command Discard Detection Setting (AxisName.Pr.StopOption_DriverTargetIgnored). If the servo parameter "Limit switch enabled status selection (PD41.2)" is set to "0: Limit switch always enabled" and limit detection is performed on the drive unit side, when stopping due to limit detection, switch to the cyclic synchronous position mode (csp) using MC_Stop (Forced Stop) or an axis stop signal.
- Wire the load cell amplifier output to the analog input of the drive unit. For details, refer to the manual of the connected device.
- For information about drive unit functions that cannot be used in the cyclic synchronous pressure mode (cspr), refer to the manual of the connected device.
- During pressure control, a load cell detector error or variations in load cell pressure may cause the axis to continue moving backward. Therefore, set the software stroke limit.
- When limiting the command pressure, change the object data "Positive pressure limit value (2E5BH)" using one of the following methods. For details on the "Positive pressure limit value (2E5BH)", refer to the manual for the connected device used.
  - Use MC_WriteParameter (Parameter Write) to change the object data "Positive pressure limit value (2E5BH)". For details on MC_WriteParameter (Parameter Write), refer to the following.
    MELSEC MX Controller MX-R Model Programming Manual
  - Map the object data "Positive pressure limit value (2E5BH)" to RPDO and create a network label. Change the value of that label. For details on network labels or PDO mapping settings, refer to the following.
    ☞ Page 108 Creation procedure for network labels
    ☞ Page 165 PDO mapping setting

Relevant object data

The following cases will result in errors and functional restrictions.

- Object data is not set.
- PDO is not mapped.
- There is no object in the device station.

For details on the object data settings, refer to the following.

☞ Page 469 Object data settings

■PDO

◎: PDO mapping is required, ○: PDO mapping is recommended

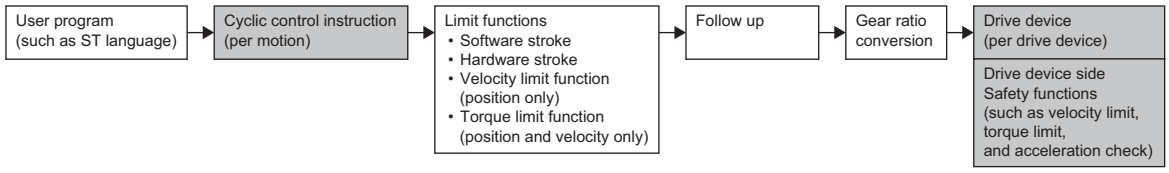
30 MOTION CYCLIC CONTROL

The motion cyclic control is a function that sends the position, velocity, and torque to the drive unit.
The motion cyclic control includes the following controls.

Control name	Driver control mode	Applicable instruction	Operation details	Reference
Motion cyclic positioning control	Cyclic synchronous position mode (csp)	MCv_CyclicPosition (position control)	Switches the control mode of the drive unit to the cyclic synchronous position mode (csp), and sends the target position.	Page 761 Motion Cyclic Positioning Control
Motion cyclic velocity control	Cyclic synchronous velocity mode (csv)	MCv_CyclicVelocity (velocity control)	Switches the control mode of the drive unit to the cyclic synchronous velocity mode (csv), and sends the target velocity.	Page 768 Motion Cyclic Velocity Control
Motion cyclic torque control	Cyclic synchronous torque mode (cst)	MCv_CyclicTorque (torque control)	Switches the control mode of the drive unit to the cyclic synchronous torque mode (cst), and sends the target torque.	Page 774 Motion Cyclic Torque Control

Point

A path such as acceleration/deceleration for sending the target position, target velocity, and target torque to the drive unit must be created in the program because no acceleration/deceleration function or torque ramp function exists. When using the acceleration/deceleration function or torque ramp function, refer to the DIRECT CONTROL.
☞ Page 710 DIRECT CONTROL



Operation of this function for each system status

Overall block diagram

The following diagram shows the relationship between the data used in the motion cyclic control and other functions.

30.1 Motion Cyclic Positioning Control

This function switches the control mode of the drive unit to the cyclic synchronous position mode (csp), and sends the target position.

Relevant variables

Axis parameter constant (AxisName.PrConst.)

Variable/structure name	Name	Details
RingCount_Enable	Ring counter enabled selection	Sets the ring counter enable/disable. • FALSE: Disabled • TRUE: Enabled
RingCount_UpperValue	Ring counter upper limit value	Sets the ring counter upper limit value.*1 • -10000000000.0 to 10000000000.0
RingCount_LowerValue	Ring counter lower limit value	Sets the ring counter lower limit value.*1 • -10000000000.0 to 10000000000.0

*1 The value is not fetched when the ring counter is disabled.

Axis parameter (AxisName.Pr.)

Variable/structure name	Name	Details
StopMode_SwStrokeLimit	Software stroke limit stop selection	Sets the operation when the software stroke limit error occurs.*1 • 1: Immediate Stop (ImmediateStop) • 2: Keep Current Acceleration/Deceleration (KeepCurrentAcc) • 3: Alternative Acceleration/Deceleration (AlternativeAcc)
SwStrokeLimit_Upper	Software stroke limit upper value	Sets the software stroke limit upper value. • -10000000000.0 to 10000000000.0
SwStrokeLimit_Lower	Software stroke limit lower value	Sets the software stroke limit lower value. • -10000000000.0 to 10000000000.0
StopMode_General	Stop selection at stop cause occurrence	Displays input status of the stop selection at stop cause occurrence. • 1: Immediate Stop (ImmediateStop) • 2: Keep Current Acceleration/Deceleration (KeepCurrentAcc) • 3: Alternative Acceleration/Deceleration (AlternativeAcc)
StopMode_DecelerationCurve	Stop selection at deceleration to stop	Sets the operation when a stop cause occurs during deceleration (including a stop cause and automatic deceleration). • 1: Recreate Deceleration Curve (OverrideCurve)
StopMode_HwStrokeLimit	Hardware stroke limit stop selection	Sets the operation when the hardware stroke limit error occurs.*1 • 1: Immediate Stop (ImmediateStop) • 2: Keep Current Acceleration/Deceleration (KeepCurrentAcc) • 3: Alternative Acceleration/Deceleration (AlternativeAcc)
VelocityLimit_Positive	Positive direction velocity limit value	Specifies the address increasing direction velocity limit value. • 0.0001 to 2500000000.0
VelocityLimit_Negative	Negative direction velocity limit value	Specifies the address decreasing direction velocity limit value. • 0.0001 to 2500000000.0
VelocityLimit_OverOperation	Operation setting at velocity limit value exceeded	Sets the operation when the velocity limit value during control is exceeded. • 0: Ignore (Ignore)*2 • 3: Immediate Stop (ImmediateStop)*3

*1 Immediate stop will be executed when executing an FB without deceleration specification.

*2 For "0: Ignore (Ignore)", if the command velocity exceeding the velocity limit value is detected, "Velocity Limit Value Over Warning (event code: 00D03H)" occurs, and the command exceeding the velocity limit value is output as it is.

*3 For "3: Immediate Stop (ImmediateStop)", if the command velocity exceeding the velocity limit value is detected, Velocity Limit Value Over during Controlling (error code: 1AA4H) occurs, and the positioning control in execution stops.

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
AxisStatus	Axis status	Displays the current axis status. • -1: Axis variable uninitialization/Axis parameter error (Invalid) • 0: Axis disabled (Disabled) • 1: Stopping on error (ErrorStop) • 2: Decelerating to stop (Stopping) • 3: During homing (Homing) • 4: Standby (Standstill) • 5: During positioning operation (DiscreteMotion) • 6: During continuous operation (ContinuousMotion) • 7: During synchronous operation (SynchronizedMotion)
SetPosition	Set position	Stores the current position address.*1 The set position is a value where the cumulative current position is rounded within the ring counter range.
SetVelocity	Set velocity	Stores the set output velocity.*1 This velocity is calculated from the difference of the set position. The value is positive when moving in the positive direction (Address increase direction), and the value is negative when moving in the negative direction (Address decrease direction). Stores the set velocity of the configuration axis during the axes group operation.
SwStrokeLimit_Target	Stroke limit target	Displays the software stroke limit target. • -1: Invalid (Invalid) • 1: Set position (SetPosition) • 3: Machine feed value (FeedMachinePosition)
FeedMachinePosition	Machine feed value	Stores the current position address by the machine coordinate. The accumulative value from the homing completed position is set. The address is not changed even if the current position is changed. The ring address is "-10000000000.0 ≤ Machine feed value < 10000000000.0".

*1 The stored value includes an error because a floating-point error occurs.

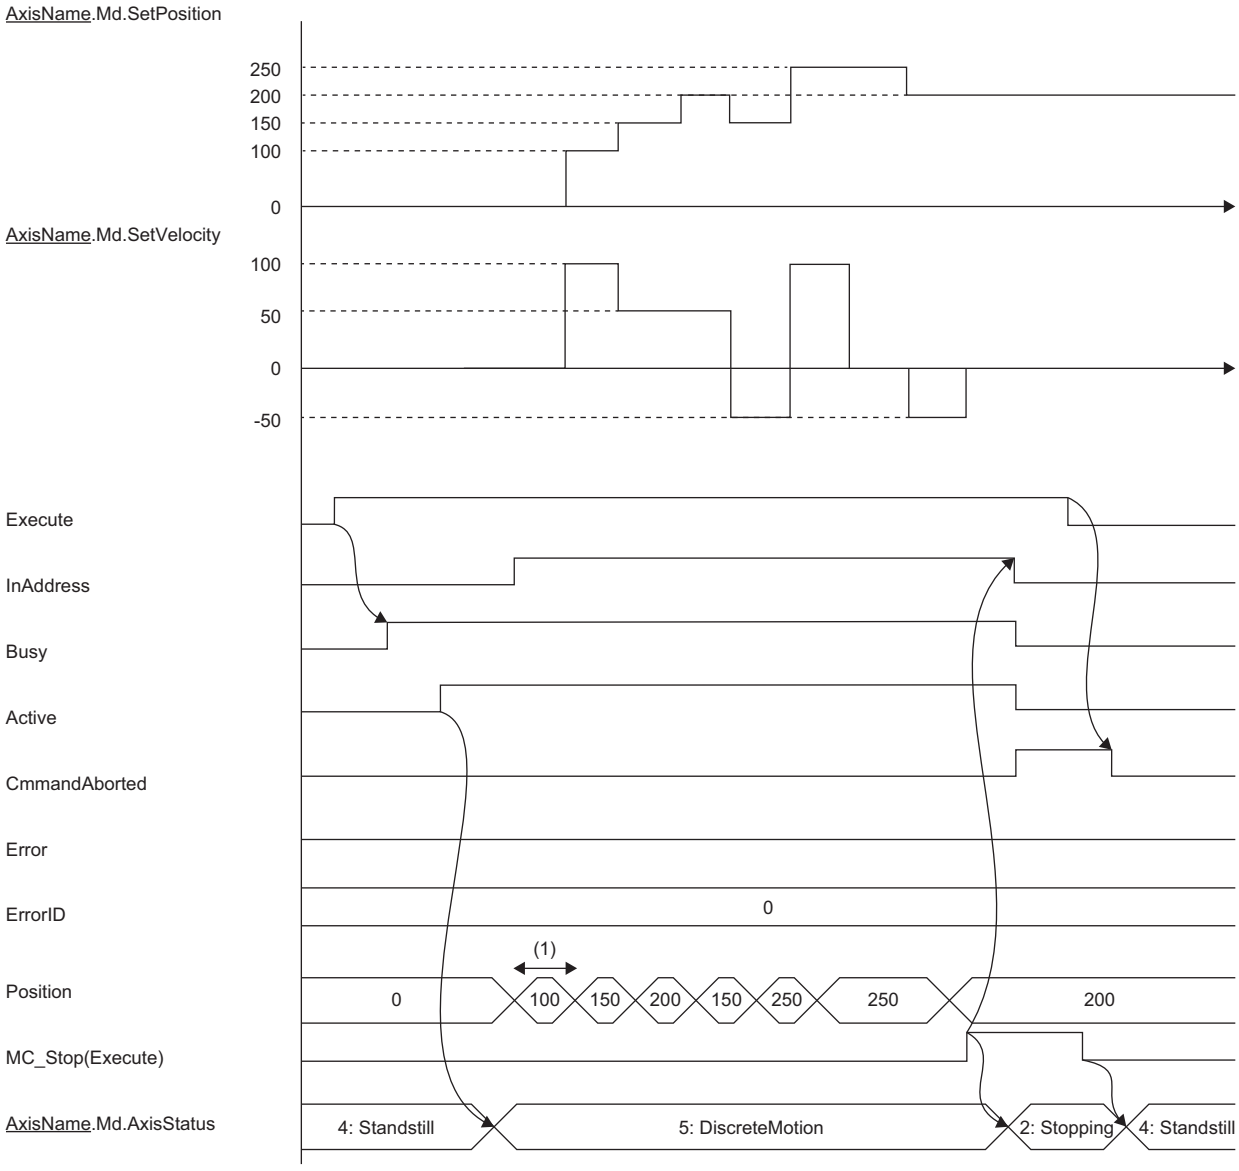
System parameter (MotionSystem.Pr)

Variable/structure name	Name	Details
StopMode_All	Stop selection at all axes stop cause occurrence	Sets whether to stop immediately or decelerate to stop when an all axes stop cause occurs. • 1: Immediate Stop (ImmediateStop) • 2: Keep Current Acceleration/Deceleration (KeepCurrentAcc) • 3: Alternative Acceleration/Deceleration (AlternativeAcc)

Relevant FB

For details on motion control FBs, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

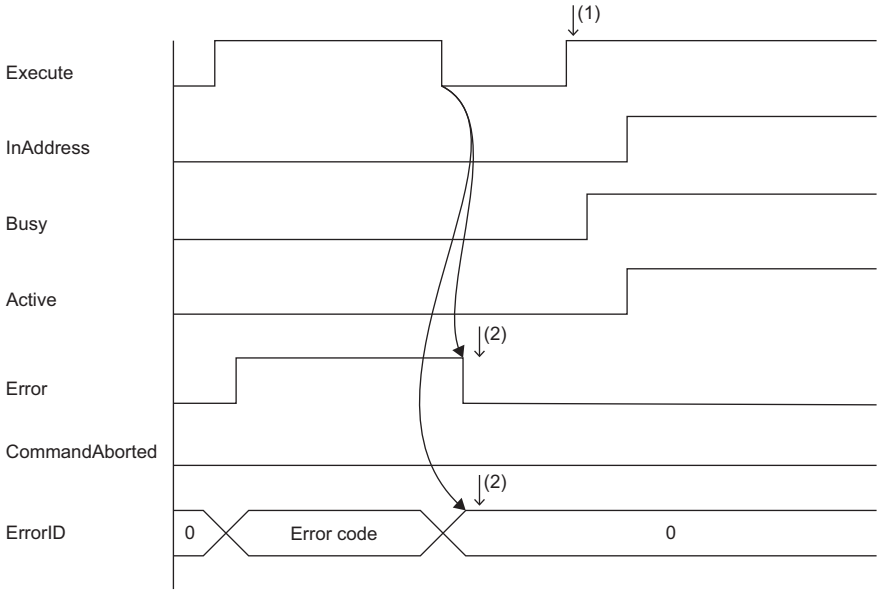


Motion control FB	Name	Description
MCv_CyclicPosition	Motion cyclic position control	Sends the target position to the drive unit according to the specified target position.

Control details

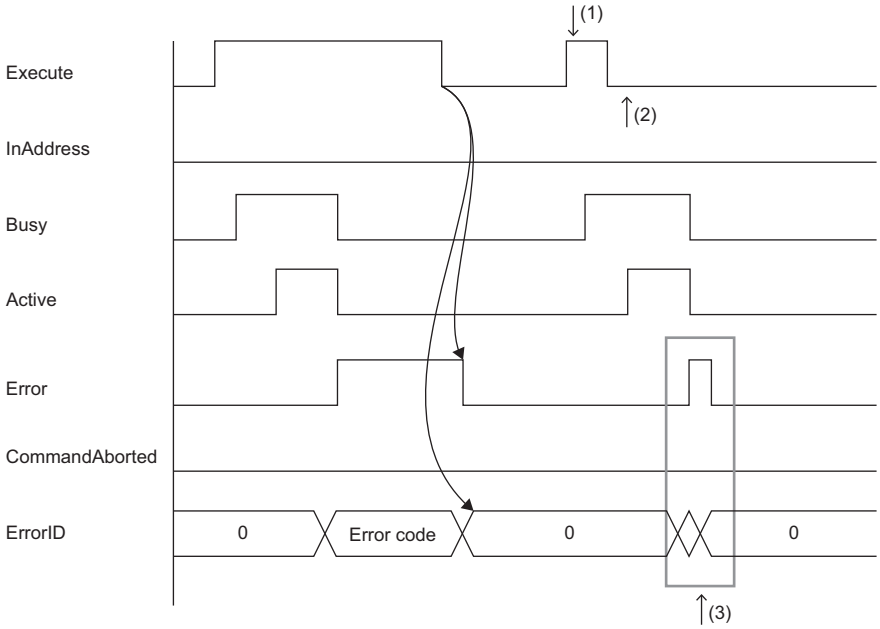
MCv_CyclicPosition (motion cyclic position control) switches the control mode of the drive unit to the csp (cyclic synchronous position mode) and executes control.
This function sends the set position without setting the acceleration, deceleration, and jerk.
To finish this FB, start MC_Stop (forced stop).

Timing chart of I/O signal



■When the processing is completed successfully

(1) One operation cycle



■When the processing is completed with an error

• When the I/O variables are abnormal

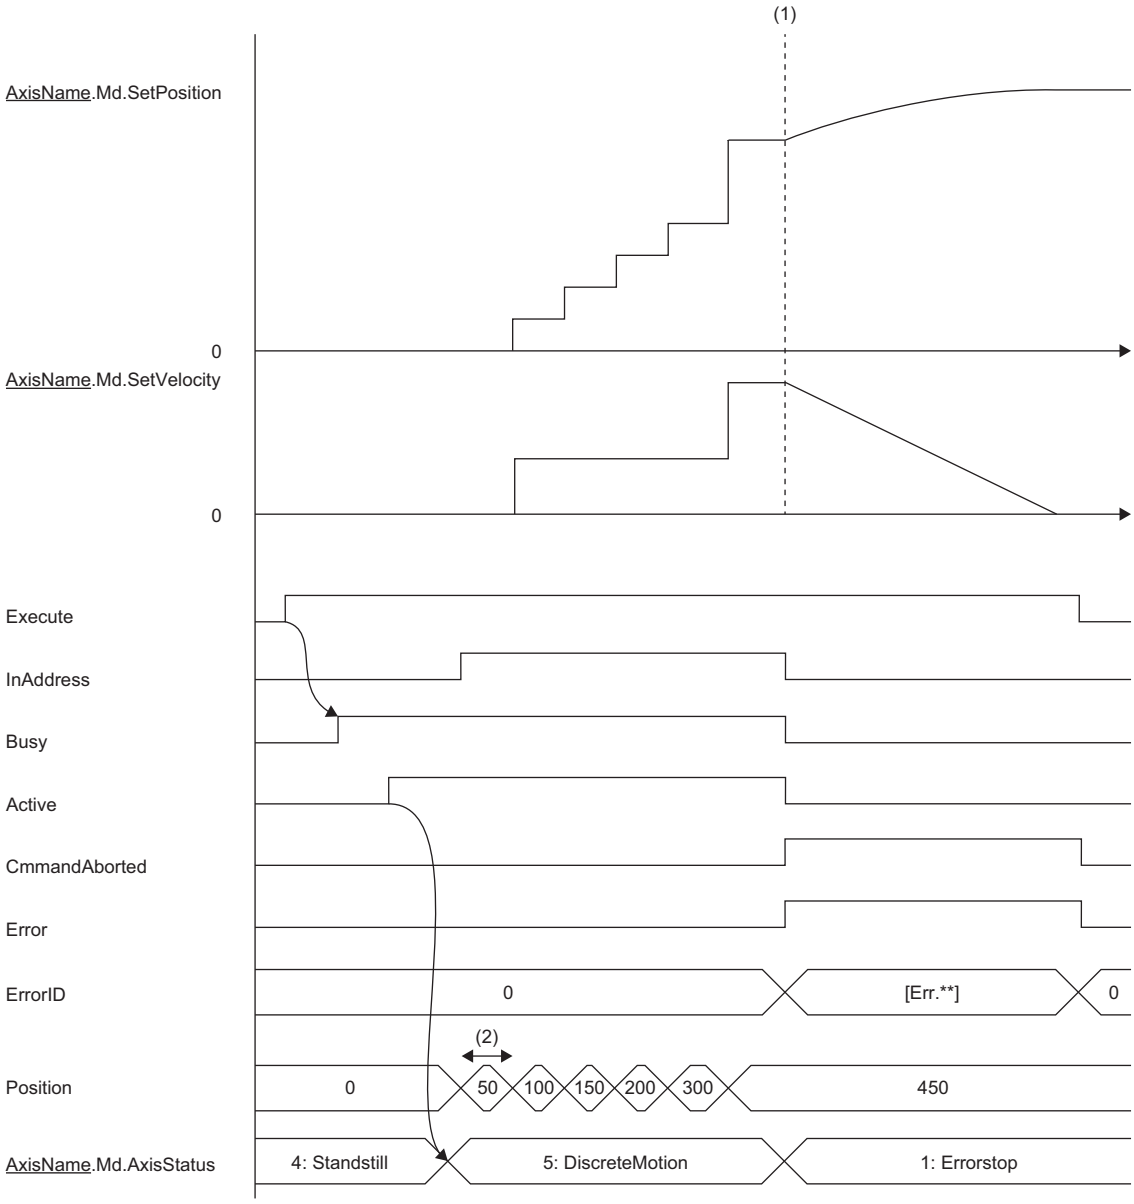
(1) Eliminate the error cause and restart.
(2) Clear when Execute falls.

• When the input variables are abnormal

(1) Eliminate the error cause and restart.
(2) Set to FALSE before error occurs.
(3) Output only one cycle.

Operation at stop cause occurrence

When a stop cause occurs during the axis operation, the axis will stop immediately or stop with deceleration depending on each cause.



For the stop cause during axis operation, refer to the following.

☞ Page 584 Stop causes during axis operation

When decelerating to stop, the axis decelerates with the trapezoidal acceleration/deceleration from the velocity stored in the Set Velocity (AxisName.Md.SetVelocity) at stop cause occurrence.

When "2: Keep Current Acceleration/Deceleration (KeepCurrentAcc)" is set for the following, the axis stops immediately instead of decelerating to stop.

- Stop selection at stop cause occurrence (AxisName.Pr.StopMode_General)
- Stop selection at hardware stroke limit error occurrence (AxisName.Pr.StopMode_HwStrokeLimit)
- Stop selection at software stroke limit error occurrence (AxisName.Pr.StopMode_SwStrokeLimit)
- Stop selection at all axes stop cause occurrence (MotionSystem.Pr.StopMode_All)

(1) Stop cause occurrence (axis error detection)
(2) One operation cycle

Relevant object data

If no object data is set, PDO mapping is not performed, or no object exists in the device station, there will be errors and restrictions in the following function.

For details on the object data settings, refer to the following.

☞ Page 466 Axis Assignment

◎: Required

Instruction/function	Required object data	PDO mapping	Operation with no object
MCv_CyclicPosition (motion cyclic position control)	Target position (607AH)	◎	Required object data unset (error code: 1AF7H) occurs.

Precautions

- Motion cyclic position control does not set acceleration, deceleration, or jerk, and may cause sudden acceleration or deceleration when sending a command position. Therefore, set a value that takes safety into consideration for the velocity limit value (Positive Direction Velocity Limit Value (AxisName.Pr.VelocityLimit_Positive) for the positive direction or Negative Direction Velocity Limit Value (AxisName.Pr.VelocityLimit_Negative) for the negative direction).
- When the set velocity exceeds the velocity limit value for each axis, the operation follows Operation Setting at Velocity Limit Value Exceeded (AxisName.Pr.VelocityLimit_OverOperation). Also, if the absolute value of the set velocity exceeds the maximum velocity, Velocity range over during controlling (error code: 1B1AH) will occur and the operation will stop.
- When switching from a control mode other than csp to csp by executing multiple start of MCv_CyclicPosition (motion cyclic position control), check that the motor has stopped before switching. If the switching is performed without stopping the motor, the difference between the current position and MCv_CyclicPosition (motion cyclic position control) may be large, resulting in rapid operation.

Program example

In the motion cyclic position control, the user can send an arbitrary position command to the drive unit for each operation cycle.

The following shows the program example that calculates the target position from the set position of axis 2 by a user-defined arbitrary function (User_Function) by setting the control start (bExecute) to TRUE, and sends the calculated target position to the drive unit of axis 1 by the motion cyclic position control.

Axis

Axis No.	Label name	Data type	Comment
1	Axis0001	AXIS_REAL	Axis 1
2	Axis0002	AXIS_REAL	Axis 2

Labels used

Label name	Data type	Comment
bExecute	Bit	Control start
bMC_MoveRelative_Execute	Bit	Relative positioning control start
MCv_CyclicPosition_1	MCv_CyclicPosition	Motion cyclic position control FB
MC_MoveRelative_1	MC_MoveRelative	Relative value positioning FB
User_Fuction_1	User_Fuction	• User-defined arbitrary function An FB defined by users. Convert the following in this program example. Target position (leUserOutput) = 10000.0 × SIN (set position (leUserInput))
leMCv_CyclicPosition	Double-precision real number	Position command calculated by the user arbitrary function

Program example

ST program

```
SET(MCv_CyclicPosition_1.Active, bMC_MoveRelative_Execute);

   User_Fuction_1(
   leUserInput:= Axis0002.Md.SetPosition ,
   leUserOutput=> leMCv_CyclicPosition
);

MCv_CyclicPosition_1(
   Axis:= Axis0001.AxisRef ,
   Execute:= bExecute,
   ContinuousUpdate:= TRUE ,
   Position := leMCv_CyclicPosition
   BufferMode:= MC_BUFFER_MODE__mcAborting ,
   Options:= 0
);

MC_MoveRelative_1(
   Axis:= Axis0002.AxisRef ,
   Execute:= bMC_MoveRelative_Execute,
   ContinuousUpdate:= TRUE ,
   Distance:= 360.0 ,
   Velocity:= 180.0 ,
   Acceleration:= 180.0 ,
   Deceleration:= 180.0 ,
   Jerk:= 0.0 ,
   BufferMode:= MC_BUFFER_MODE__mcAborting ,
   Options:= 0
);
```

30.2 Motion Cyclic Velocity Control

This function switches the control mode of the drive unit to the cyclic synchronous velocity mode (csv), and sends the target velocity.

Relevant variables

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
Io_TargetVelocity	Object Data_TargetVelocity	Displays the value of object data TargetVelocity. (The velocity command to send to devices)
AxisStatus	Axis status	Displays the current axis status. • -1: Axis variable uninitialization/Axis parameter error (Invalid) • 0: Axis disabled (Disabled) • 1: Stopping on error (ErrorStop) • 2: Decelerating to stop (Stopping) • 3: During homing (Homing) • 4: Standby (Standstill) • 5: During positioning operation (DiscreteMotion) • 6: During continuous operation (ContinuousMotion) • 7: During synchronous operation (SynchronizedMotion)
Driver_Mode	Driver control mode	Displays the driver control mode status. • 6: Homing (hm) • 8: Position control (csp) • 9: Velocity control (csv) • 10: Torque control (cst) • -104: Continuous operation to torque control (ct)
SetPosition	Set position	Stores the current position address.*1 The set position is a value where the cumulative current position is rounded within the ring counter range.
SetVelocity	Set velocity	Stores the set output velocity.*1 This velocity is calculated from the difference of the set position. The value is positive when moving in the positive direction (Address increase direction), and the value is negative when moving in the negative direction (Address decrease direction). Stores the set velocity of the configuration axis during the axes group operation.

*1 The stored value includes an error because a floating-point error occurs.

Axis parameter constant (AxisName.PrConst.)

Variable/structure name	Name	Details
RingCount_Enable	Ring counter enabled selection	Sets the ring counter enable/disable. • 0: Disable • 1: Enable
RingCount_UpperValue	Ring counter upper limit value	Sets the ring counter upper limit value.*1 • -10000000000.0 to 10000000000.0
RingCount_LowerValue	Ring counter lower limit value	Sets the ring counter lower limit value.*1 • -10000000000.0 to 10000000000.0

*1 The value is not fetched when the ring counter is disabled.

Axis parameter (AxisName.Pr.)

Variable/structure name	Name	Details
StopMode_General	Stop selection at stop cause occurrence	Sets the operation when a stop cause occurs. • 1: Immediate Stop (ImmediateStop) • 2: Keep Current Acceleration/Deceleration (KeepCurrentAcc) • 3: Alternative Acceleration/Deceleration (AlternativeAcc) * Immediate stop will be executed when executing an FB without deceleration specification.
StopMode_DecelerationCurve	Stop selection at deceleration to stop	Sets the operation when a stop cause occurs during deceleration (including a stop cause and automatic deceleration). • 1: Recreate Deceleration Curve (OverrideCurve)
StopMode_HwStrokeLimit	Stop selection at hardware stroke limit error occurrence	Sets the operation when the hardware stroke limit error occurs. • 1: Immediate Stop (ImmediateStop) • 2: Keep Current Acceleration/Deceleration (KeepCurrentAcc) • 3: Alternative Acceleration/Deceleration (AlternativeAcc) * Immediate stop will be executed when executing an FB without deceleration specification.
VelocityLimit_Positive	Positive direction velocity limit value	Sets the address increasing direction velocity limit value. • 0.0001 to 2500000000.0
VelocityLimit_Negative	Negative direction velocity limit value	Sets the address decreasing direction velocity limit value. • 0.0001 to 2500000000.0
VelocityLimit_OverOperation	Operation setting at velocity limit value exceeded	Sets the operation when the velocity limit value during control is exceeded. • 0: Ignore (Ignore) • 3: Immediate Stop (ImmediateStop) * For "0: Ignore (Ignore)", if the command velocity exceeding the velocity limit value is detected, Velocity Limit Value Over Warning (event code: 0D03H) occurs, and the command exceeding the velocity limit value is output as it is. * For "3: Immediate Stop (ImmediateStop)", if the command velocity exceeding the velocity limit value is detected, Velocity Limit Value Over during Controlling (error code: 1AA4H) occurs, and the positioning control in execution stops.

System parameter (MotionSystem.Pr)

Variable/structure name	Name	Details
StopMode_All	Stop selection at all axes stop cause occurrence	Sets whether to stop immediately or decelerate to stop when an all axes stop cause occurs. • 1: Immediate Stop (ImmediateStop) • 2: Keep Current Acceleration/Deceleration (KeepCurrentAcc) • 3: Alternative Acceleration/Deceleration (AlternativeAcc)

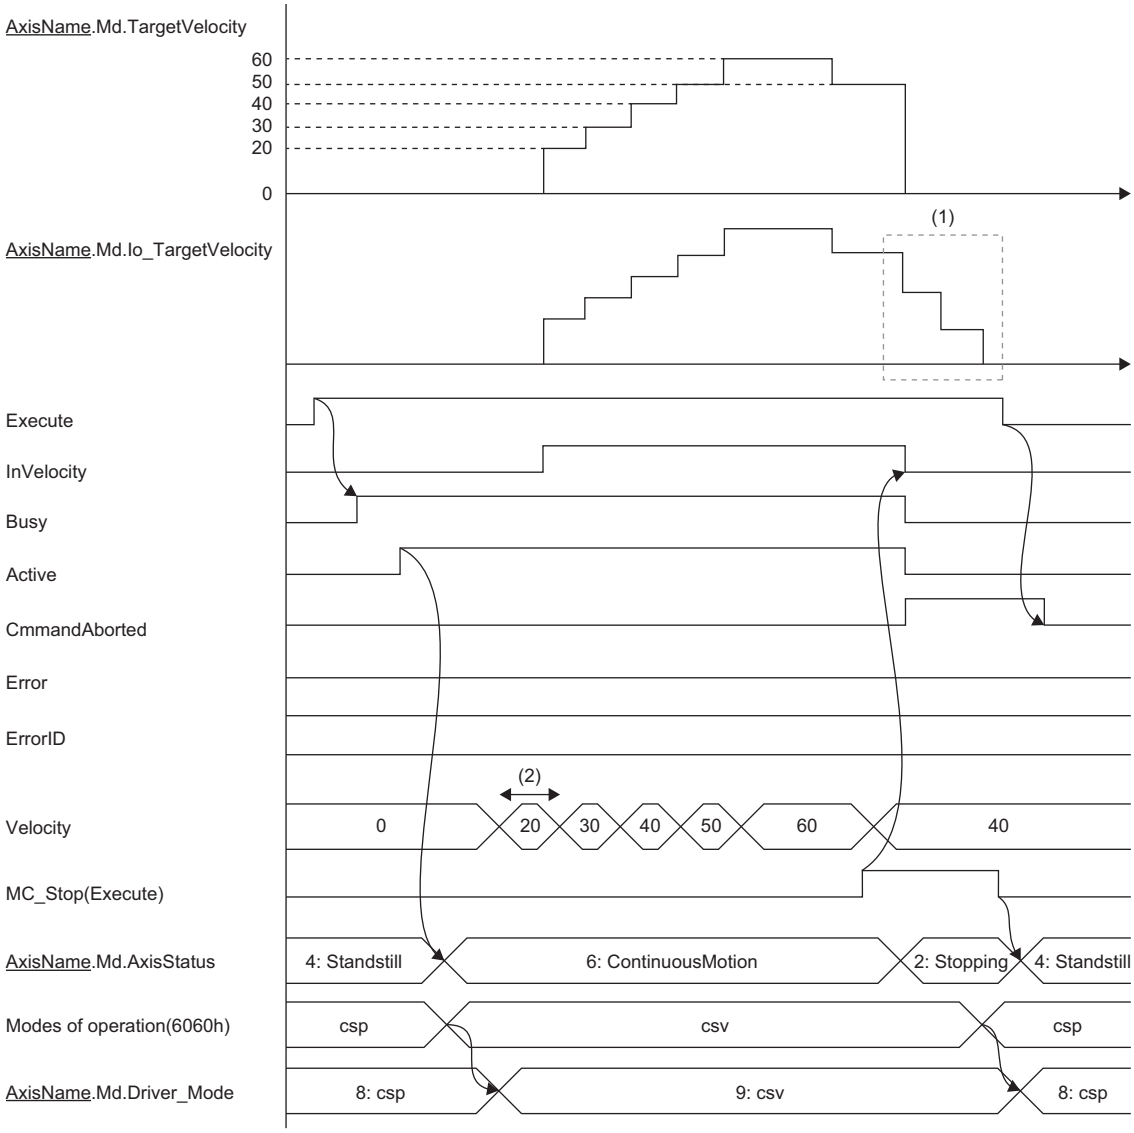
Relevant FBs

For details on motion control FBs, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

Motion control FB	Name	Description
MCv_CyclicVelocity	Motion cyclic velocity control	Sends the target velocity to the drive unit according to the specified target velocity.

Control details



MCv_CyclicVelocity (motion cyclic velocity control) switches the control mode of the drive unit to the csv (cyclic synchronous velocity mode) and executes control.

This function controls only the command velocity without setting the acceleration, deceleration, and jerk.

To finish this FB, start MC_Stop (forced stop).

Timing chart of I/O signal

■When the processing is completed successfully

(1) Decelerate to stop by MC_Stop (forced stop)
(2) One operation cycle

■When the processing is completed with an error

Same as the operation of the motion cyclic position control.

☞ Page 764 When the processing is completed with an error

Operation at stop cause occurrence

For the stop cause during axis operation, refer to the following.

☞ Page 716 Operation at stop cause occurrence

When "2: Keep Current Acceleration/Deceleration (KeepCurrentAcc)" is set for the following, the axis stops immediately instead of decelerating to stop.

- Stop selection at stop cause occurrence (AxisName.Pr.StopMode_General)
- Stop selection at hardware stroke limit error occurrence (AxisName.Pr.StopMode_HwStrokeLimit)
- Stop selection at software stroke limit error occurrence (AxisName.Pr.StopMode_SwStrokeLimit)
- Stop selection at all axes stop cause occurrence (MotionSystem.Pr.StopMode_All)

Relevant object data

If no object data is set, PDO mapping is not performed, or no object exists in the device station, there will be errors and restrictions in the following function.

For details on the object data settings, refer to the following.

☞ Page 466 Axis Assignment

◎: Required

Instruction/function	Required object data	PDO mapping	Operation with no object
MCv_CyclicVelocity (motion cyclic velocity control)	Target velocity (60FFH)	◎	Required object data unset (error code: 1AF7H) occurs.

Precautions

- When setting the target velocity, set the value so that the difference between the current velocity and the target velocity is not large. If the difference is large, the axis may accelerate suddenly.
- The set position and the machine feed value are updated by follow-up.
- Time until the control mode is switched depends on the specifications of the drive unit.
- When the stop cause occurs during the control mode switching, the axis will stop immediately.
- Do not start the positioning control FB during the control mode switching. Start the positioning control FB after checking that Driver Control Mode (AxisName.Md.Driver_Mode) is switched to "9: Velocity control (csv)".
- When switching from csp to csv or from csv to csp without waiting for stop of the motor with the MR-J5(W)-G, set "ZSP disabled selection at control switching (PC76.1)" of the servo parameter to "1: Disabled" and disable monitoring of zero speed status. However, note that it may cause vibration or impact at control mode switching. There are restrictions on the setting value of the servo parameter "Electronic gear numerator (PA06)" and "Electronic gear denominator (PA07)". For details, refer to the following.

☞ Page 2152 Connection to Servo Amplifier That Supports CC-Link IE TSN

Program example

In the motion cyclic velocity control, the user can send an arbitrary target velocity to the drive unit for each operation cycle. The following shows the program example that calculates the target velocity of axis 1 from the set position of axis 2 by a user-defined arbitrary function (User_Function) by setting the control start (bExecute) to TRUE, and sends the calculated target velocity to the drive unit of axis 1 by the motion cyclic velocity control.

Axis

Axis No.	Label name	Data type	Comment

    BufferMode:= MC_BUFFER_MODE__mcAborting ,
    Options:= 0
);
```

30.3 Motion Cyclic Torque Control

This function switches the control mode of the drive unit to the cyclic synchronous torque mode (cst), and sends the target torque.

Relevant variables

Axis parameter constant (AxisName.PrConst.)

Variable/structure name	Name	Details
SlaveObject	Object data	Sets the object data to the real drive axis.
vVelLimitValue	VelLimitValue	Sets the velocity limit value in the drive unit.

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
Cst_SetTorque	Set torque at cst/ct	Stores set torque at the cyclic synchronous torque mode.
Cst_SetLimitVelocity	Set limit velocity at cst/ct/cspr	Stores the command limit velocity in the cyclic synchronous torque mode (cst), continuous operation to torque control mode (ct), and cyclic synchronous pressure mode (cspr).
Io_TorqueActualValue	Object Data_TorqueActualValue	Displays the value of object data Torque actual value (6077H). (The actual torque to be received from the device station)
AxisStatus	Axis status	Displays the current axis status. • -1: Axis variable uninitialization/Axis parameter error (Invalid) • 0: Axis disabled (Disabled) • 1: Stopping on error (ErrorStop) • 2: Decelerating to stop (Stopping) • 3: During homing (Homing) • 4: Standby (Standstill) • 5: During positioning operation (DiscreteMotion) • 6: During continuous operation (ContinuousMotion) • 7: During synchronous operation (SynchronizedMotion)
Driver_Mode	Driver control mode	Displays the driver control mode status. • 6: Homing (hm) • 8: Position control (csp) • 9: Velocity control (csv) • 10: Torque control (cst) • -104: Continuous operation to torque control (ct)
TorqueLimit_Positive	Positive direction torque limit value	Displays the positive direction torque limit value that is currently valid.
TorqueLimit_Negative	Negative direction torque limit value	Displays the negative direction torque limit value that is currently valid.

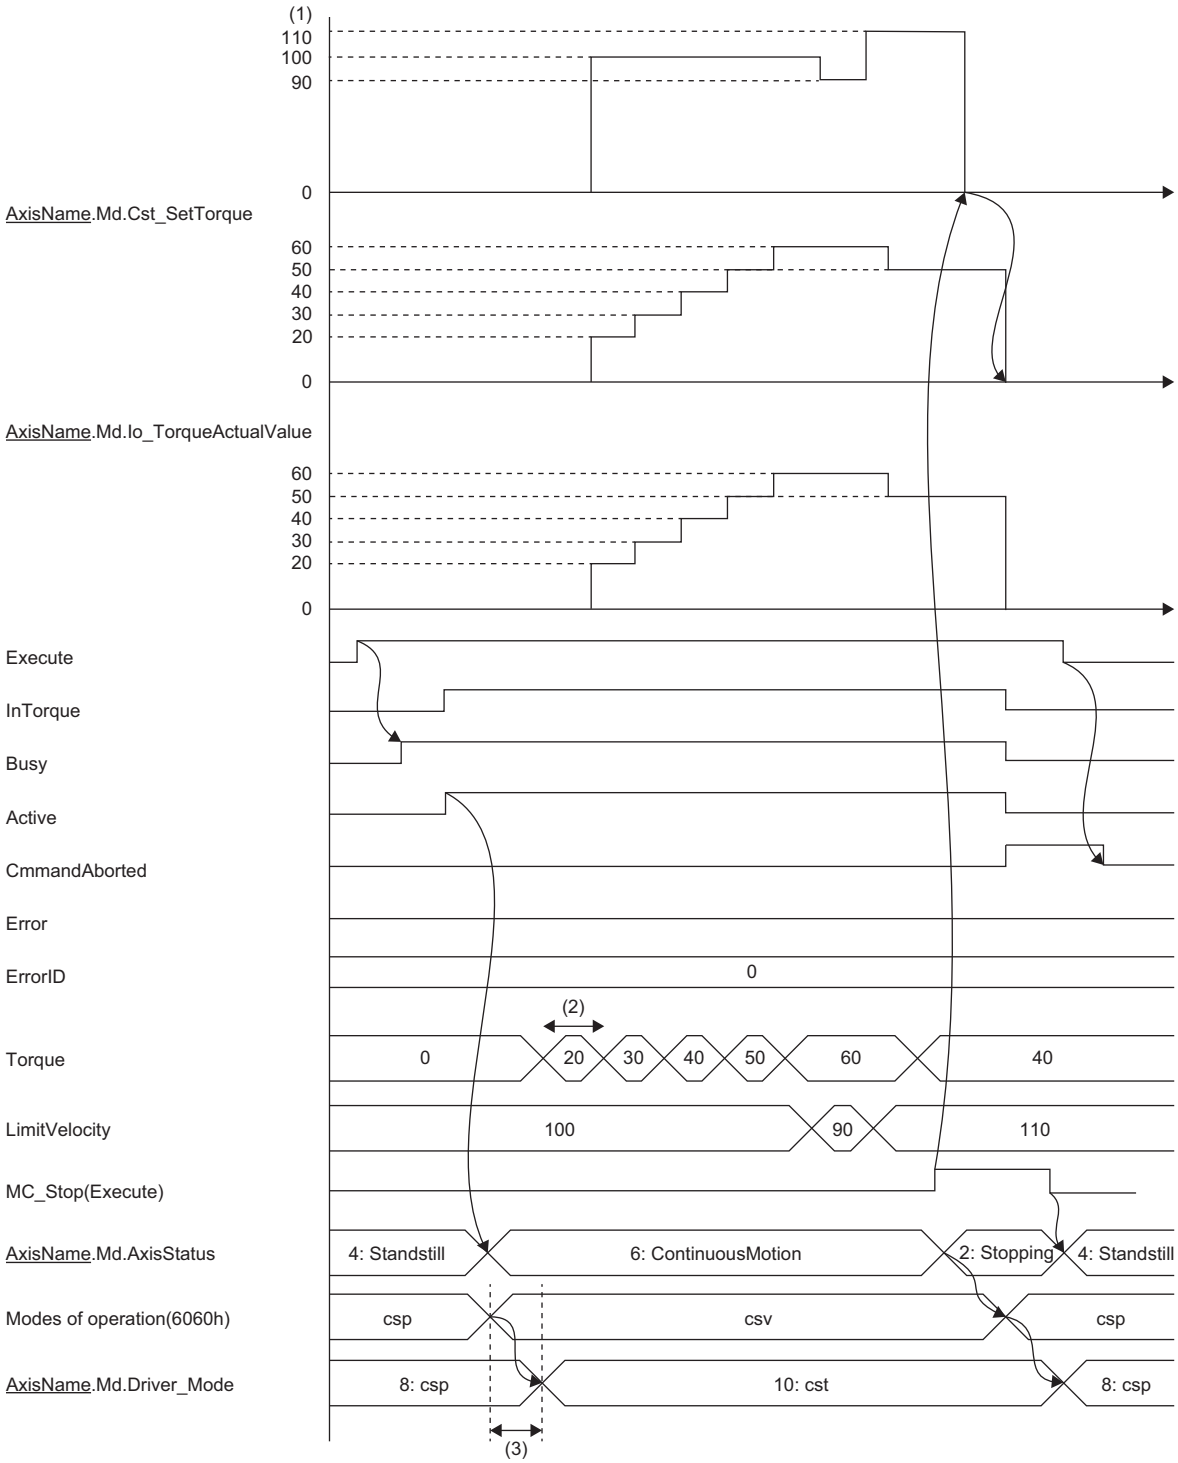
Relevant FB

For details on motion control FBs, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

Motion control FB	Name	Description
MCv_CyclicTorque	Cyclic torque control	Sends the target torque to the drive unit according to the specified target position.

Control details



MCv_CyclicTorque (cyclic torque control) switches the control mode of the drive unit to the cst (cyclic synchronous torque mode) and executes control.

The velocity limit value and set torque are sent to the drive unit.

To finish this FB, start MC_Stop (forced stop).

☞ Page 727 Relation between torque generation direction of servo motor and set torque

Relevant object data

If no object data is set, PDO mapping is not performed, or no object exists in the device station, there will be errors and restrictions in the following function.

For details on the object data settings, refer to the following.

☞ Page 466 Axis Assignment

◎: Required, ○: Recommended

Instruction/function	Required object data	PDO mapping	Operation with no object
MCv_CyclicTorque (cyclic torque control)	Target torque (6071H)	◎	Required object data unset (error code: 1AF7H) occurs.
	Velocity limit value (2D20H)	○	The velocity limit during cst (cyclic synchronous torque mode) by the LimitVelocity (limit velocity) cannot be used. If the difference between the current torque and the target torque is large, the velocity may increase rapidly, causing a dangerous situation depending on the mechanism and the load method. For details on the velocity limit, refer to MCv_CyclicTorque (cyclic torque control) in the following manual. 📖MELSEC MX Controller MX-R Model Programming Manual

Precautions

- The set position and the machine feed value are updated by follow-up.
- Time until the control mode is switched depends on the specifications of the drive unit.
- When the stop cause occurs during the control mode switching, the axis will stop immediately.
- Do not start the positioning control FB during the control mode switching. Start the positioning control FB after checking that Driver Control Mode (AxisName.Md.Driver_Mode) is switched to "10: Torque control (cst)".
- When the torque set to the target torque is not sufficient, it may be dangerous because the torque is released rapidly depending on the mechanism and load. When the target torque is to be reduced, pay close attention to safety.
- When the axis is stopped, store the value in the limit velocity (LimitVelocity) after the control mode is switched. When the value is stored in the limit velocity (LimitVelocity) before switching, the velocity may increase rapidly, causing a dangerous situation.
- For the torque limit change during the cst (cyclic synchronous torque mode), at restart or continuous update, if the target torque is changed to a value larger than the torque limit value (Positive Direction Torque Limit Value (AxisName.Md.TorqueLimit_Positive), Negative Direction Torque Limit Value (AxisName.Md.TorqueLimit_Negative)), Torque Limit Value Over Warning (event code: 00D12H) occurs and the axis operates at the value before change. During torque control, if Positive Direction Torque Limit Value (AxisName.Cd.TorqueLimit_Positive) or Negative Direction Torque Limit Value (AxisName.Cd.TorqueLimit_Negative) is changed to a value smaller than the target torque, the target torque will be changed to the torque limit value. In this case, the set torque is changed in one operation cycle.

Program example

In the motion cyclic torque control, the user can send an arbitrary target torque to the drive unit for each operation cycle. The following shows the program example that calculates the target torque from the set position of axis 2 by a user-defined arbitrary function (User_Function) by setting the control start (bExecute) to TRUE, and sends the calculated target torque to the drive unit of axis 1 by the motion cyclic torque control.

Axis

Axis No.	Label name	Data type	Comment
1	Axis0001	AXIS_REAL	Axis 1
2	Axis0002	AXIS_REAL	Axis 2

Labels used

Label name	Data type	Comment
bExecute	Bit	Control start
bMC_MoveRelative_Execute	Bit	Relative positioning control start
MCv_CyclicTorque_1	MCv_CyclicTorque	Motion cyclic torque control FB
MC_MoveRelative_1	MC_MoveRelative	Relative value positioning FB
User_Fuction_1	User_Fuction	• User-defined arbitrary function An FB defined by users. Convert the following in this program example. Target torque (leUserOutput) = 100.0 × SIN (set position (leUserInput))
leMCv_CyclicTorque	Double-precision real number	Target torque calculated by the user arbitrary function

Program example

ST program

```
SET(MCv_CyclicTorque_1.Active, bMC_MoveRelative_Execute);

    User_Fuction_1(
    leUserInput:= Axis0002.Md.SetPosition ,
    leUserOutput=> leMCv_CyclicTorque
);

MCv_CyclicTorque_1(
    Axis:= Axis0001.AxisRef ,
    Execute:= bExecute,
    ContinuousUpdate:= TRUE ,
    Torque := leMCv_CyclicTorque
    LimitVelocity:= 10000.0 ,
    BufferMode:= MC_BUFFER_MODE__mcAborting ,
    Options:= 0
);

MC_MoveRelative_1(
    Axis:= Axis0002.AxisRef ,

    Deceleration:= 180.0 ,
    Jerk:= 0.0 ,
    BufferMode:= MC_BUFFER_MODE__mcAborting ,
    Options:= 0
);
```

30.4 Precautions on Motion Cyclic Control

- A call program of motion control FB for motion cyclic position/motion cyclic velocity/motion cyclic torque control should match the Control Cycle Setting (AxisName.PrConst.OperationCycle) of the axis specified in the input variable Axis. Otherwise, unintended operation may occur. The recommended setting example is as shown below.

Ex.

When the control cycle setting of the axis set to MCv_CyclicPosition.Axis is "0: Automatic setting", and the communication period setting of the device station to be controlled is "Basic period"

The MCv_CyclicPosition (motion cyclic position control) should be executed in the programs set below.

Item	Setting
Program type	Event execution type
Trigger type of event execution type	Network communication period synchronization
Network communication period synchronization	Basic period

- For motion cyclic position/motion cyclic velocity/motion cyclic torque control, some functions are disabled. The controls of disabled functions are ignored.

Function	Motion cyclic position control	Motion cyclic velocity control	Motion cyclic torque control
Velocity override function	Disable	Disable	Disable
Acceleration override	Disable	Disable	Disable
Velocity limit value	Enable*1	Enable*2	Disable
Acceleration limit value/deceleration limit value	Disable	Disable	Disable
Jerk limit value	Disable	Disable	Disable
Bias velocity at start	Disable	Disable	Disable

*1 The velocity limit is not executed at start. During control, if the set velocity exceeds the velocity limit value (Positive Direction Velocity Limit Value (AxisName.Pr.VelocityLimit_Positive) for the positive direction and Negative Direction Velocity Limit Value (AxisName.Pr.VelocityLimit_Negative) for the negative direction) of each axis, Velocity limit value over during controlling (error code: 1AA4H) will occur and the axis will stop immediately.
If the absolute value of the set velocity exceeds the maximum velocity, Velocity range over during controlling (error code: 1B1AH) will occur and the operation will stop.

*2 For the operation at velocity limit value exceeded, refer to the following.
☞ Page 1113 For single axis control

- The control change at the cycle where a stop cause such as MC_Stop occurs is ignored. An example is shown below.

Ex.

As shown in the following timing chart, even if the control of MCv_CyclicPosition.Position is changed at the same timing as the cycle in which the stop cause occurs, the new value is ignored.

☞ Page 765 Operation at stop cause occurrence

Relevant add-ons

The following add-ons are required to use this function.

- MotionControl_Cyclic
- MotionEngine
- MotionControl_General
- NetworkDriver_CCIETSN (When using a real axis)
- ServoDriver_CANopen (When using a real axis)

31 SYNCHRONOUS CONTROL

The synchronous control has the following items.

Item	Description	Reference
Cam operation	Operates by synchronizing the slave axis with the master axis based on cam table.	Page 784 Cam Operation
Gear operation	Sets the speed ratio between the master axis and the slave axis, and enters gear operation.	Page 816 Gear Operation
Addition/Subtraction positioning	Combines the movement amount of two axes and transmits.	Page 819 Addition/ Subtraction Positioning

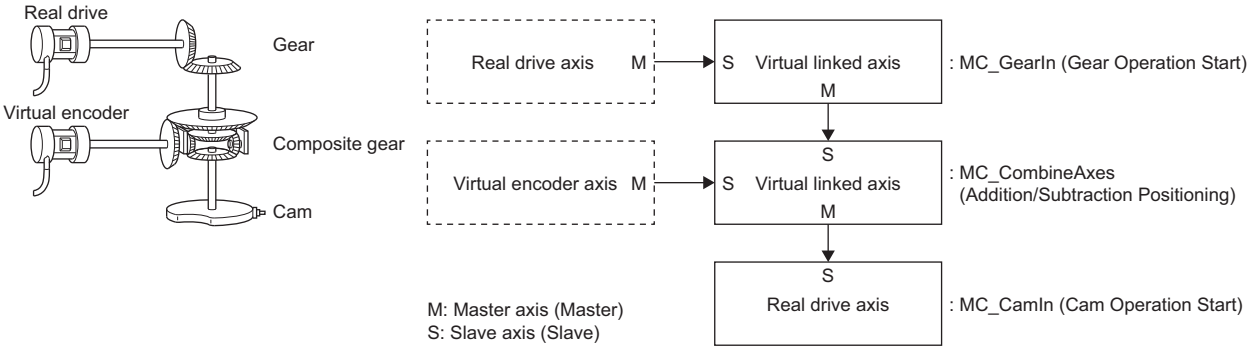
31.1 Overview of Single Axis Synchronous Control FBs

Single axis synchronous control FBs enable to control mechanical systems such as gears, speed change gears, and cams with software by transmitting the position information (command) of Slave axis (Slave) that is synchronized with Master axis (Master).

FB	Control details
MC_CamIn (Cam Operation Start)	Executes cam operation.
MC_GearIn (Gear Operation Start)	Sets the speed ratio between the master axis and the slave axis, and enters gear operation.
MC_CombineAxes (Addition/Subtraction Positioning)	Combines operations of two axes by a selectable combination method, and outputs it to the third axis.
MCv_ChangeCycle (Current Value Change per Cycle)	Changes the current value per cycle to the specified value during MC_CamIn (Cam Operation Start) control. It is used to adjust the current value per cycle to any desired value.
MCv_BacklashCompensationFilter (Backlash Compensation Filter)	Performs the specific filter processing to input of Master axis (Master), and outputs the result to Slave axis (Slave). ☞ Page 1133 COMMAND FILTER
MCv_SmoothingFilter (Smoothing Filter)	
MCv_DirectionFilter (Moving Direction Restriction Filter)	
MCv_SpeedLimitFilter (Speed Limit Filter)	
MCv_AdvancedSync (Advanced Synchronous Control)	Starts synchronization control according to the specified advanced synchronization control settings. ☞ Page 889 ADVANCED SYNCHRONOUS CONTROL

31.2 Axis Configuration

The following shows axes that can be set to Master axis (Master) and Slave axis (Slave) in the single axis synchronous control FBs. For the specifications of each axis type, refer to the following.



☞ Page 443 Axis
☞ Page 466 Axis Assignment

Axis type		Used for Master axis (Master)	Used for Slave axis (Slave)	Remark
Real axis	Real drive axis	○	○	When control for multiple motion FBs is required, create a configuration that executes function blocks for each virtual linked axis and transmits the result (command) to the real drive axis.
	Real encoder axis	○	×	It is used as Master axis (Master). When it is used as Slave axis (Slave), Necessary Object Data Unset (error code: 1AF7H) occurs and it does not start.
Virtual axis	Virtual drive axis	○	○	Commands can be mainly created by positioning control or others.
	Virtual encoder axis	○	×	It is used as Master axis (Master). When it is used as Slave axis (Slave), Necessary Object Data Unset (error code: 1AF7H) occurs and it does not start.
	Virtual linked axis	○	○	It is used as an intermediate axis to transmit a command to the real drive axis. When using multiple motion FBs such as gear, assign virtual linked axes.

To combine and execute controls such as gear and cam, use the virtual linked axis like the following example.

Ex.

To process gear following the instruction of the real drive axis and perform cam control adding the instruction from the virtual encoder

Position command unit of the master axis and the slave axis

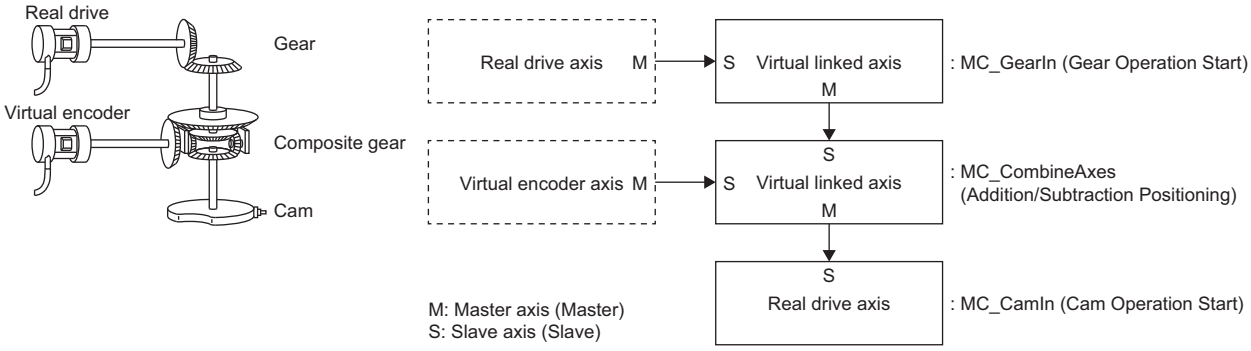
Settings of position command unit of the master axis and the slave axis (Position Command Unit (AxisName.Pr.Unit_Position) and Position Command Unit String (AxisName.Pr.Unit_PositionString)) do not affect the control. The result of the calculation performed to the position information of the master axis which has no unit information is used as an instruction of the slave axis.

Ex.

To add each master axis by gear ratio 1:1 using MC_CombineAxes (Addition/Subtraction Positioning)

The slave axis moves 3.0 [degrees] with the following settings of position command unit of each axis when master axis 1 moves 1.0 [pulse] and master axis 2 moves 2.0 [mm].

- Position command unit of the master axis 1: pulse
- Position command unit of the master axis 2: mm
- Position command unit of the slave axis: degree



Current position change of the master axis

The set position of the slave axis does not change even when the current position change of the master axis is performed.

31.3 Master Axis Data Source Selection

In the single axis synchronous control FB, the position type of the master axis whose slave axis executes the single axis synchronous control can be selected by Master axis data source selection (MasterValueSource) of each FB.
When the actual value is specified for a virtual axis (axis which does not have Actual Position (AxisName.Md.ActualPosition)), the FB operates with the same value as the set value.
"101: Latest Set Value (mcLatestSetValue)" and "102: Latest Actual Value (mcLatestActualValue)" use a position of the master axis in the same operation cycle, and the others use a position of the master axis in the previous operation cycle.
Using "101: Latest Set Value (mcLatestSetValue)" and "102: Latest Actual Value (mcLatestActualValue)" can transmit the multiple motion control FB commands in the same operation cycle. In this case, set the first call order and linking order of the linked motion control FB to be the same.

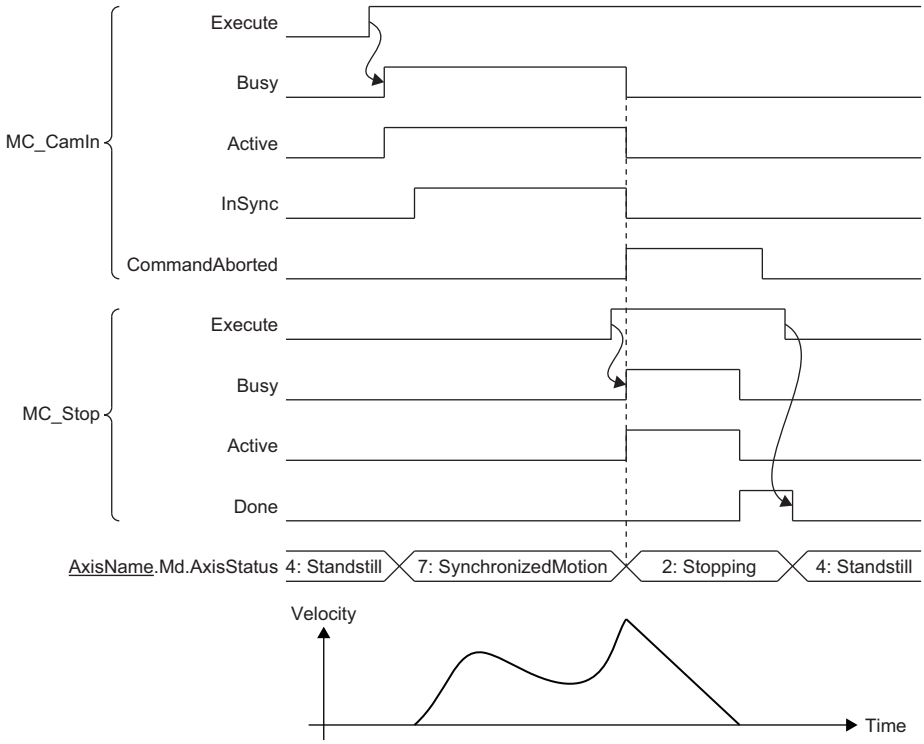
Ex.
When transmitting the movement of the real drive axis and virtual encoder axis for cam control in the same operation cycle

When using the above combination of the single synchronous control FB (linked order), set the first call order as follows.

1. Motion control FB which moves the master axis (real drive axis) of MC_GearIn (Gear Operation Start)
2. MC_GearIn (Gear Operation Start)
3. MC_CombineAxes (Addition/Subtraction Positioning)
4. MC_CamIn (Cam Operation Start)

• Master axis data source selection (MasterValueSource) of each single axis synchronous control FB
"101: Latest Set Value (mcLatestSetValue)"

Point



When Master axis data source selection (MasterValueSource) is set to "1: Set Value (mcSetValue)" or "101: Latest Set Value (mcLatestSetValue)" and the master axis becomes servo OFF or disconnected by a servo alarm or forced stop, the amount of the value change may be too large. This can be prevented by setting Master axis data source selection (MasterValueSource) to "2: Actual value (mcActualValue)" or "102: Latest actual value (mcLatestActualValue)".

Master axis data source selection (MasterValueSource)	Description
1: Set Value (mcSetValue)	Uses the commanded position of the master axis in the previous operation cycle.
2: Actual Value (mcActualValue)	Uses the actual position of the master axis in the previous operation cycle.
101: Latest Set Value (mcLatestSetValue)	Uses the commanded position of the master axis in the current operation cycle.
102: Latest Actual Value (mcLatestActualValue)	Uses the actual position of the master axis in the current operation cycle.

31.4 Stop Operation

Slave axis (Slave) continues to control with the command transmitted by Master axis (Master) even if a stop cause occurs on the master axis during execution of the synchronous control FB. The axis status of the slave axis does not change.
When a stop cause occurs on the slave axis, the axis status transits and the slave axis immediately stops or stops with deceleration according to the stop cause and its stop process. For axis control when a stop cause occurs, refer to the following.
☞ Page 584 Stop causes during axis operation
The master axis is not affected even when the stop cause occurs on the slave axis.

Ex.
When a stop cause (MC_Stop (Forced Stop)) occurs during execution of the synchronous control FB

Point

When the master axis becomes servo OFF by the servo alarm or forced stop, stopping the operation of the synchronous control FB by using MC_Stop (Forced stop) is recommended because the slave axis may cause unexpected operation.

31.5 Required Object Data

The following shows the starting availability condition with or without PDO mapping when using it as the slave axis of the synchronous control FB.

PDO mapping necessary/not necessary		Starting availability
Target position	Position actual value	
Necessary	Not required	Starting is possible
Not necessary	Necessary	Starting is not possible*1
Not necessary	Not necessary	Starting is possible

*1 Necessary object data unset (error code: 1AF7H) occurs and it will not start.

31.6 Restrictions

- When Master axis (Master) and Slave axis (Slave) are specified to the same axis, Master axis and slave axis No. duplicated (error code: 1AACH) will occur.
- When connecting multiple axes in the synchronous control FB, if the master axis is set to Slave axis (Slave) of the latter FB or 257 or more synchronous control FBs are linked, Master axis and slave axis cyclic reference (error code: 1AADH) occurs.

31.7 Cam Operation

This function operates by synchronizing the slave axis with the master axis based on the cam table.
Before using this function, it is necessary to open the cam table to the open area and set to a state where it can be controlled.
For the open method to the open area, and for data types that can be controlled in cam operation, refer to the following.
☞ Page 863 Operating operation profile data
☞ Page 826 Operation profile data types

Relevant variable

Axis Monitor Data (AxisName.Md.)

Variable/structure name	Name	Details
ProfileID	Execution Profile ID No.	Stores the executing Cam table ID (CamTableID). The update timing is as follows. ■Stores the specified Cam table ID (CamTableID) • When MC_CamIn (Cam Operation Start) is executed (Timing when the slave axis status becomes "7: During synchronous operation (SynchronizedMotion)") • When changing Cam table ID (CamTableID) The timing differs depending on the setting value of Start mode (StartMode). ■Cleared to "0" • When Cam cycle completion (EndOfProfile) becomes TRUE with the setting in which Periodic (Periodic) is "FALSE: Non periodic" and Specifying operation after one cycle operation (Options (Options): bit 16) is "0: Complete" • When stop cause occurs

Relevant FB

For details on motion control FBs, refer to the following.
📖MELSEC MX Controller MX-R Model Programming Manual

Motion control FB	Name	Description
MC_CamIn	Cam operation start	Cam operation starts operation according to the specified cam table.

Control details

MC_CamIn (Cam Operation Start) sets Master axis offset (MasterOffset), Slave axis offset (SlaveOffset), Master axis scaling (MasterScaling), Slave axis scaling (SlaveScaling), Master axis follow-up distance (MasterStartDistance), Master axis synchronization start position (MasterSyncPosition), Start mode (StartMode), Master axis data source selection (MasterValueSource), Cam table ID (CamTableID), and Buffer mode (BufferMode) and then executes the cam operation.
To stop the operation, execute MC_Stop (Forced Stop).

Starting cam operation

Synchronous timing of the cam operation and reflection timing of the cam control data can be selected by setting of Start mode (StartMode).
Start mode (StartMode) has the following setting values. Each setting value is used for the following applications.

Start mode (StartMode)	Applications	Reference
0: Immediate (mcImmediate)	• When performing MC_CamIn (Cam Operation Start) after performing initial position alignment • When it is not necessary to consider detailed positional relationships such as linear cams • When MC_CamIn (Cam Operation Start) is performed due to multiple start (buffering)	☞ Page 787 When Start Mode (StartMode) is "0: Immediate (mcImmediate)"
1: Absolute (mcAbsolute)	• When MC_CamIn (Cam Operation Start) is performed from the specified master axis position • When switching the cam table ID during control by MC_CamIn (Cam Operation Start)	☞ Page 792 When Start mode (StartMode) is "1: Absolute (mcAbsolute)"
2: Relative (mcRelative)	• When restarting from the current slave axis position after stopping synchronous control while the synchronous position relationship*1 is not broken	☞ Page 797 When Start mode (StartMode) is "2: Relative (mcRelative)"
3: Ramp In (mcRampIn)	• When performing MC_CamIn (Cam Operation Start) after automatic initial position alignment*2 • When restarting with automatic initial position alignment after the device has been forcibly stopped and the synchronous position relationship*2 has been broken	☞ Page 800 When Start mode (StartMode) is "3: Ramp In (mcRampIn)"

*1 If the cam starts operating while the synchronous position relationship is broken, the slave axis may move suddenly to the initial stroke position of the cam, causing a shock to the machine.

*2 The slave axis is controlled toward the slave axis position at the start of synchronization. For operation details, refer to the following.
☞ Page 800 When Start mode (StartMode) is "3: Ramp In (mcRampIn)"

■Cam operation synchronous timing

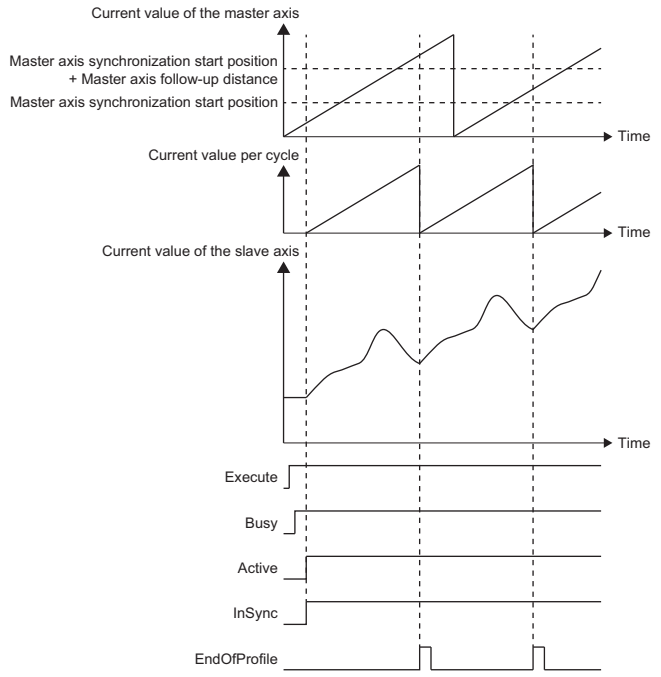
Settings of Start mode (StartMode) as well as related parameters (Master axis synchronization start position (MasterSyncPosition), and Master axis follow-up distance (MasterStartDistance)) decide the synchronous start timing of Current value per cycle (InputPerCycle), Reference value (Reference), and Output value (OutputData) as follows.

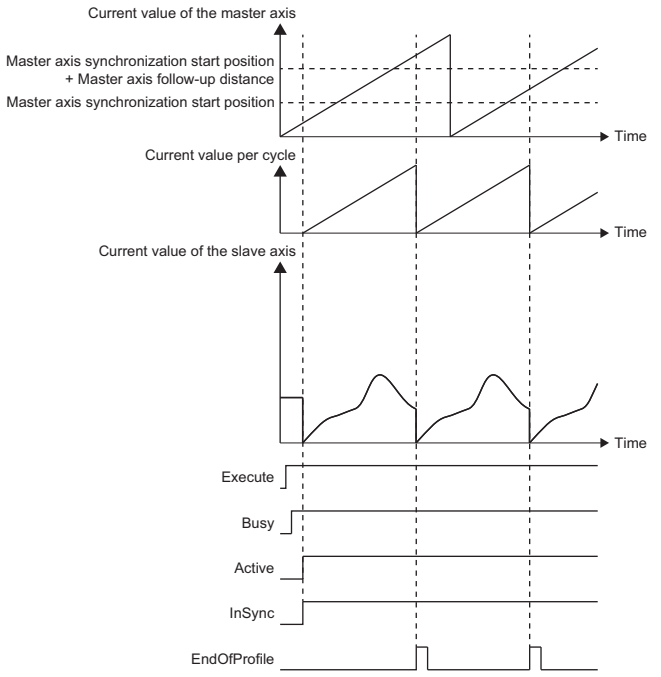
Start mode (StartMode)	Synchronous start timing	
	Current value per cycle (InputPerCycle), reference value (Reference)	Output value (OutputData)
0: Immediate (mcImmediate)	When executing MC_CamIn (Cam Operation Start) (Ignores Master axis synchronization start position (MasterSyncPosition) and Master axis follow-up distance (MasterStartDistance).)	
1: Absolute (mcAbsolute)	When the position of master axis*1 passes Master axis synchronization start position*2 (MasterSyncPosition) (Ignores Master axis follow-up distance (MasterStartDistance).)	
2: Relative (mcRelative)	When the position of the master axis*1 passes Master axis synchronization start position*2 (MasterSyncPosition)	When the position of the Master axis*1 passes Master axis synchronization start position (MasterSyncPosition) and then passes*2 "Master axis synchronization start position (MasterSyncPosition) + Master axis follow-up distance (MasterStartDistance)"
3: Ramp In (mcRampIn)		When the position of the Master axis*3 passes Master axis synchronization start position (MasterSyncPosition) and then passes*2 "Master axis synchronization start position (MasterSyncPosition) + Master axis follow-up distance (MasterStartDistance)"*3

*1 The position data to be used can be specified with Specifying target of Master axis synchronization start position pass check (Options (Options) bit 21) of MC_CamIn (Cam Operation Start).

*2 The position of the Master axis has crossed over Master axis synchronization start position (MasterSyncPosition) (or the Master axis synchronization start position (MasterSyncPosition) + Master axis follow-up distance (MasterStartDistance)). When these values are the same, the Master axis is considered to have not passed, and should the Master axis move from this value, it will be considered to have passed.

*3 After the position of the Master axis passes Master axis synchronization start position (MasterSyncPosition), the slave axis is controlled to move toward the slave axis position at the start of synchronization until it passes "Master axis synchronization start position (MasterSyncPosition) + Master axis follow-up distance (MasterStartDistance)". For details, refer to the following.





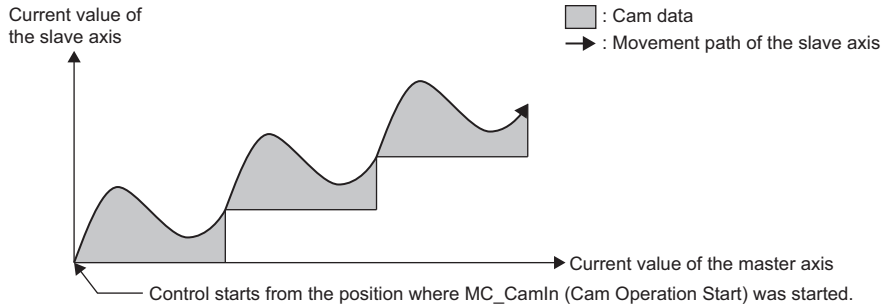
☞ Page 800 When Start mode (StartMode) is "3: Ramp In (mcRampIn)"

After MC_CamIn (Cam Operation Start) is executed, Controlling (Active) becomes TRUE after Current value per cycle (InputPerCycle) is synchronized, and then In synchronization (InSync) becomes TRUE after Output value (OutputData) is synchronized.

■When Start Mode (StartMode) is "0: Immediate (mcImmediate)"

The slave axis starts moving after start of Execution command (Execute).

The following explains the operation based on Slave axis absolute coordinate (SlaveAbsolute) set by MC_CamTableSelect (Cam Table Selection).



When Slave axis absolute coordinate (SlaveAbsolute) is "FALSE: Relative coordinate"	When Slave axis absolute coordinate (SlaveAbsolute) is "TRUE: Absolute coordinate"
	

• An example program for performing MC_CamIn (Cam Operation Start) is shown below.

Ex.

When performing MC_CamIn (Cam Operation Start) after performing initial position alignment

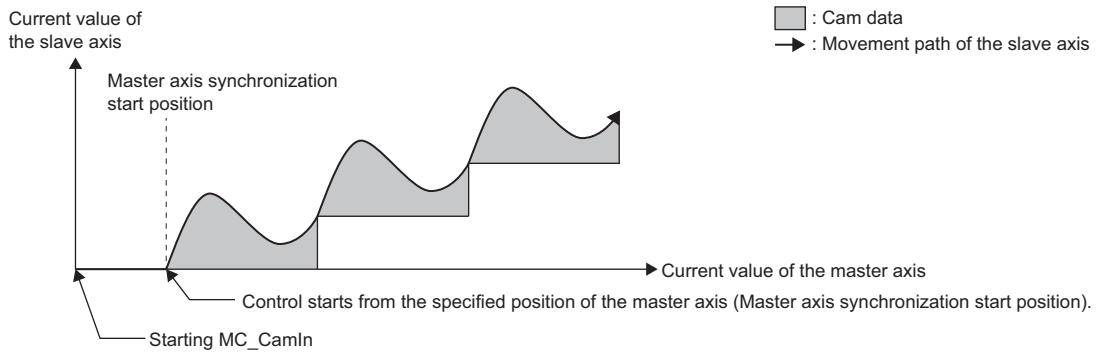
MC_CamIn_3(Master:= Axis0001.AxisRef, Slave:= Axis0002.AxisRef);
```

■When Start mode (StartMode) is "1: Absolute (mcAbsolute)"

After start of Execution command (Execute), the slave axis starts moving after the cumulative current position of the master axis passes Master axis synchronization start position (MasterSyncPosition).

Checking of whether the Master axis cumulative current position has passed the Master axis synchronization start position (MasterSyncPosition) begins at the point when the Slave axis status becomes "7: During synchronous operation (SynchronizedMotion)".

The following explains the operation based on Slave axis absolute coordinate (SlaveAbsolute) set by MC_CamTableSelect (Cam Table Selection).



When Slave axis absolute coordinate (SlaveAbsolute) is "FALSE: Relative coordinate"	When Slave axis absolute coordinate (SlaveAbsolute) is "TRUE: Absolute coordinate"
	

• An example program for performing MC_CamIn (Cam Operation Start) is shown below.

MC_CamIn_1(Master:= Axis0001.AxisRef, Slave:= Axis0002.AxisRef);
```

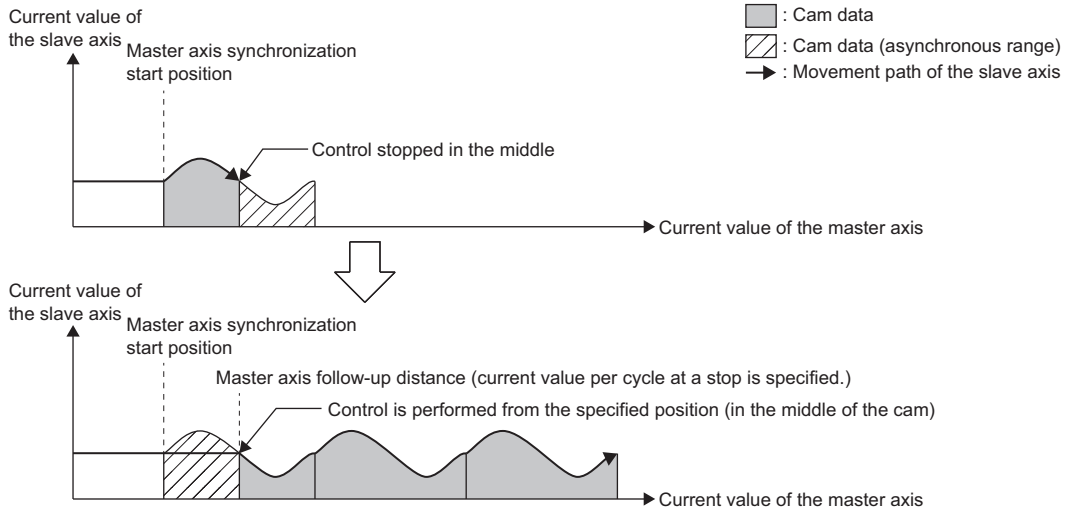
■When Start mode (StartMode) is "2: Relative (mcRelative)"

After start of Execution command (Execute), the cumulative current position of the master axis passes Master axis synchronization start position (MasterSyncPosition), and then Current value per cycle (InputPerCycle) is updated. From here, the cumulative current position of the master axis moves Master axis follow-up distance (MasterStartDistance), and then the slave axis starts moving according to the cam data.

Checking of whether the Master axis cumulative current position has passed the Master axis synchronization start position (MasterSyncPosition) begins at the point when the Slave axis status becomes "7: During synchronous operation (SynchronizedMotion)".

The following explains the operation based on Slave axis absolute coordinate (SlaveAbsolute) set by MC_CamTableSelect (Cam Table Selection).



When Slave axis absolute coordinate (SlaveAbsolute) is "FALSE: Relative coordinate"	When Slave axis absolute coordinate (SlaveAbsolute) is "TRUE: Absolute coordinate"
	

- An example program for performing MC_CamIn (Cam Operation Start) is shown below.

Ex.

When restarting from the current slave axis position after stopping synchronous control while the synchronous position relationship is not broken

```

■Timing of control change by FB restart/continuous update

Timing of reflecting changed parameters by FB restart/continuous update onto the control varies depending on Start Mode (StartMode) as shown below.

Start mode (StartMode)	Timing for reflecting parameters
0: Immediate (mcImmediate)	Immediate
1: Absolute (mcAbsolute)	When the current value per cycle (InputPerCycle) passes the first point on the cam table
2: Relative (mcRelative)	
3: Ramp In (mcRampIn)	

When the changed values exceed the range, the error is output and the control is maintained by keeping the value before.

Parameter	Event
Master axis offset (MasterOffset)	Out of Synchronous Control Variable Range Warning (event code: 00D49H) (detail code 0001H: Out of master axis offset range)
Slave axis offset (SlaveOffset)	Out of Synchronous Control Variable Range Warning (event code: 00D49H) (detail code 0002H: Out of slave axis offset range)
Master axis scaling (MasterScaling)	Out of Synchronous Control Variable Range Warning (event code: 00D49H) (detail code 0003H: Out of master axis coefficient range)
Slave axis scaling (SlaveScaling)	Out of Synchronous Control Variable Range Warning (event code: 00D49H) (detail code 0004H: Out of slave axis coefficient range)
Cam table ID (CamTableID)	• When the Cam table ID (CamTableID) value is out of range Out of Synchronous Control Variable Range Warning (event code: 00D49H) (detail code 0005H: Out of cam table ID range) • When there is no Cam table ID (CamTableID) open area No Cam Table warning (event code: 00D44H)

Cam table

This section describes the cam data and the cam operation when MC_CamIn (Cam Operation Start) is executed.

○: Used for control, ×: Not used for control

Name	Variable name	Interpolation method specification (Interpolate)			Remark
		0: Linear interpolation	1: Section interpolation	2: Spline interpolation	
Repetitive operation	Periodic	○	○		The item set in the expand setting of the operation profile data or set in input variables of MC_CamTableSelect (Cam Table Selection) on the engineering tool
Master axis absolute coordinate	MasterAbsolute	○	○		
Slave axis absolute coordinate	SlaveAbsolute	○	○		
Interpolation method specification	Interpolate	○	○		The item related to control among the data expanded to open area from the operation profile data of cam data format/rotary cutter format
Length per cycle	CycleLength	○	○		
Stroke amount	Stroke	○	○		
Start point	StartPoint	×	×		
Initial stroke amount	StartStroke	×	○		

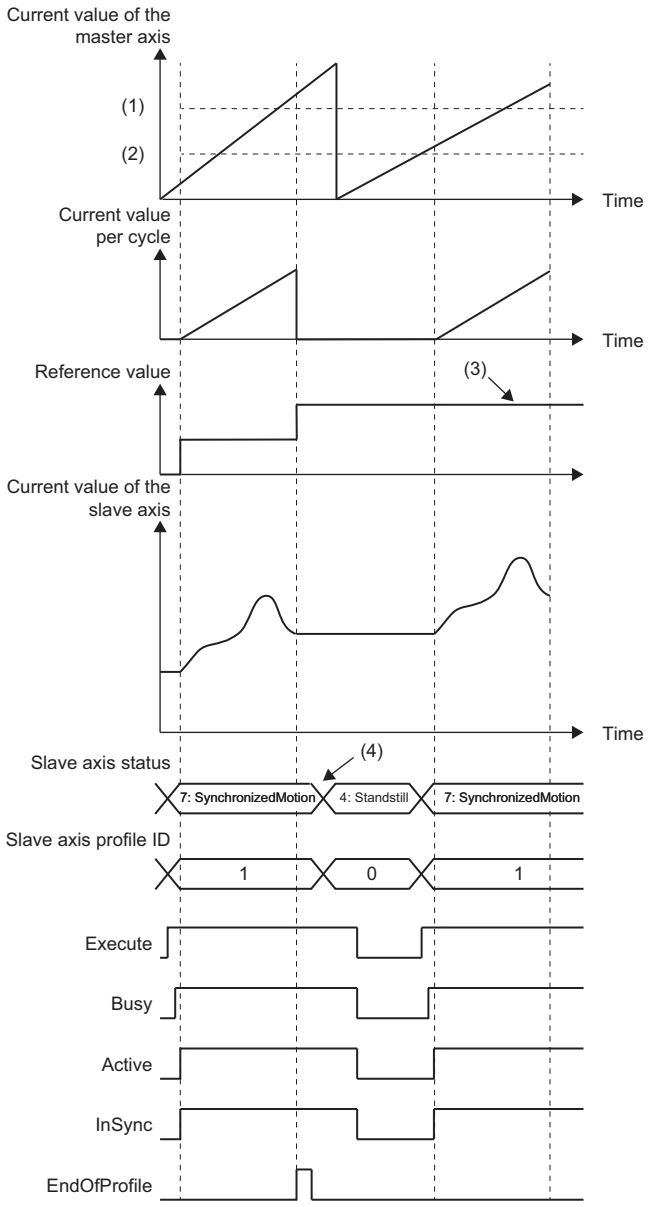
■Repetitive operation

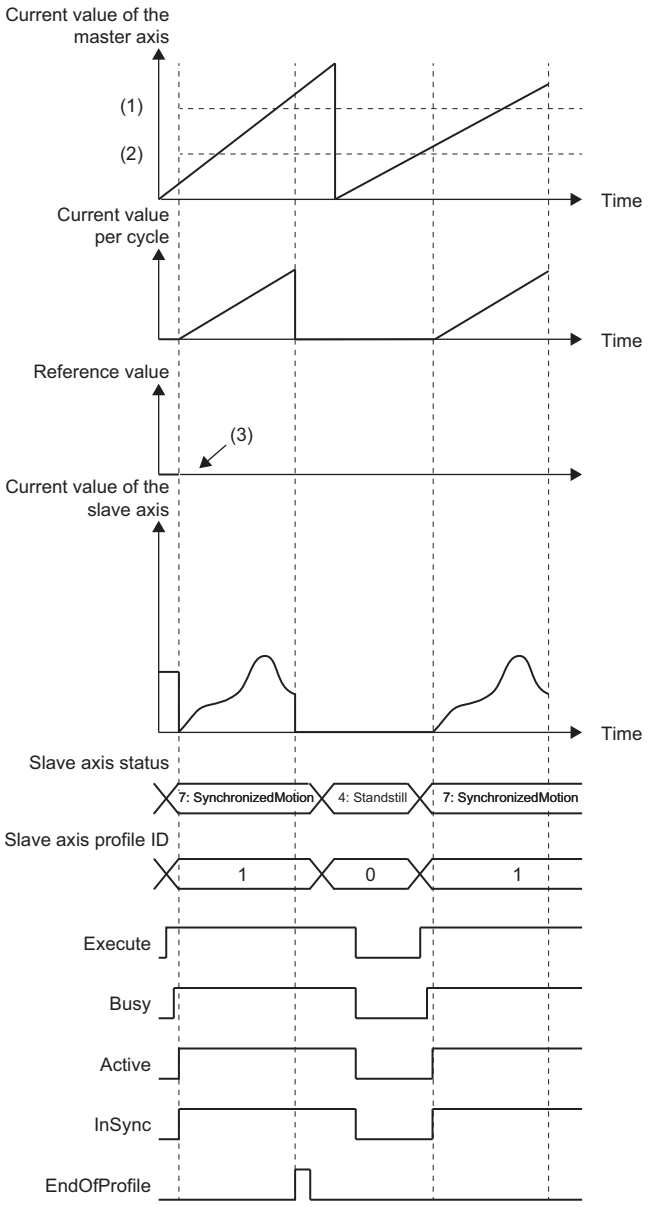
Periodic (Periodic) can set the operation after one cycle operation to "FALSE: Non periodic" or "TRUE: Periodic".

The following explains the operation when executing MC_CamIn (Cam Operation Start).

• FALSE: Non periodic

Only one cycle operation is performed after Controlling (Active) becomes TRUE. The next operation is specified in Specifying operation after one cycle operation (Options (Options): bit 16).





Specifying operation after one cycle operation (Options (Options): bit 16)	Operation after one cycle operation				Reference value (Reference), Output value (OutputData) at restart
	Executing (Busy)	Controlling (Active)	In synchronization (InSync)	Axis status (AxisName.Md.AxisStatus)	
0: Complete	FALSE			"4: Standby (Standstill)"	Initialized*1
1: Wait for restart	TRUE			"7: During synchronous operation (SynchronizedMotion)" is maintained.	Maintained

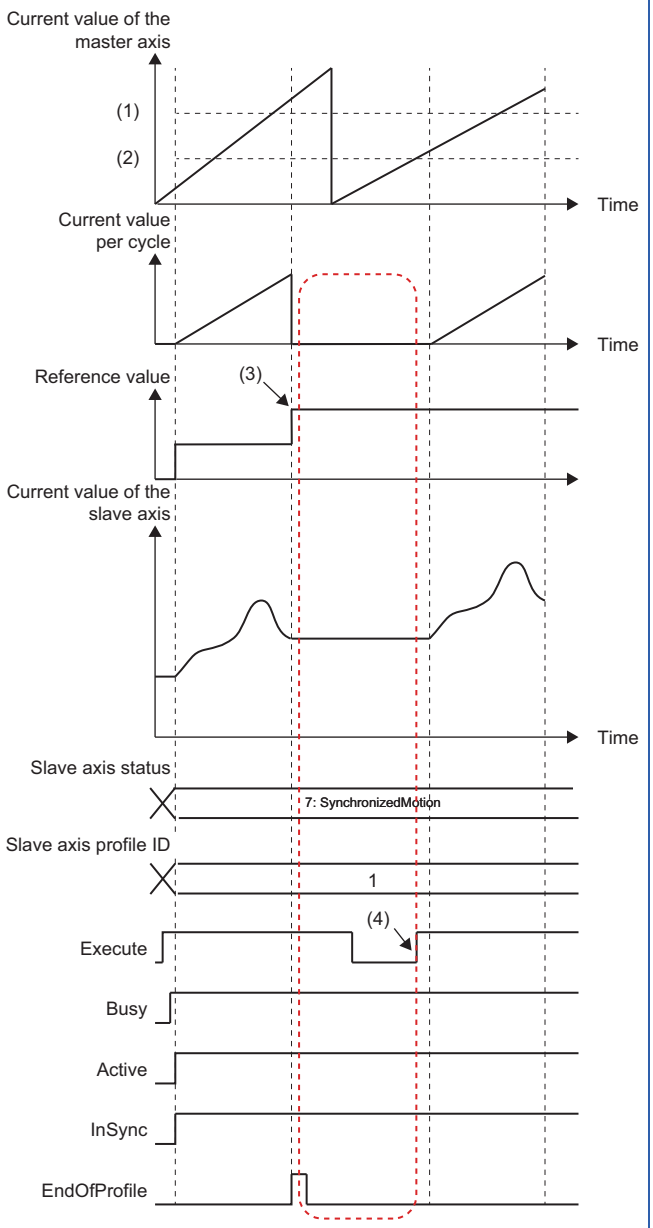
*1 For information on how to calculate the initial values of each monitor data, refer to the following.

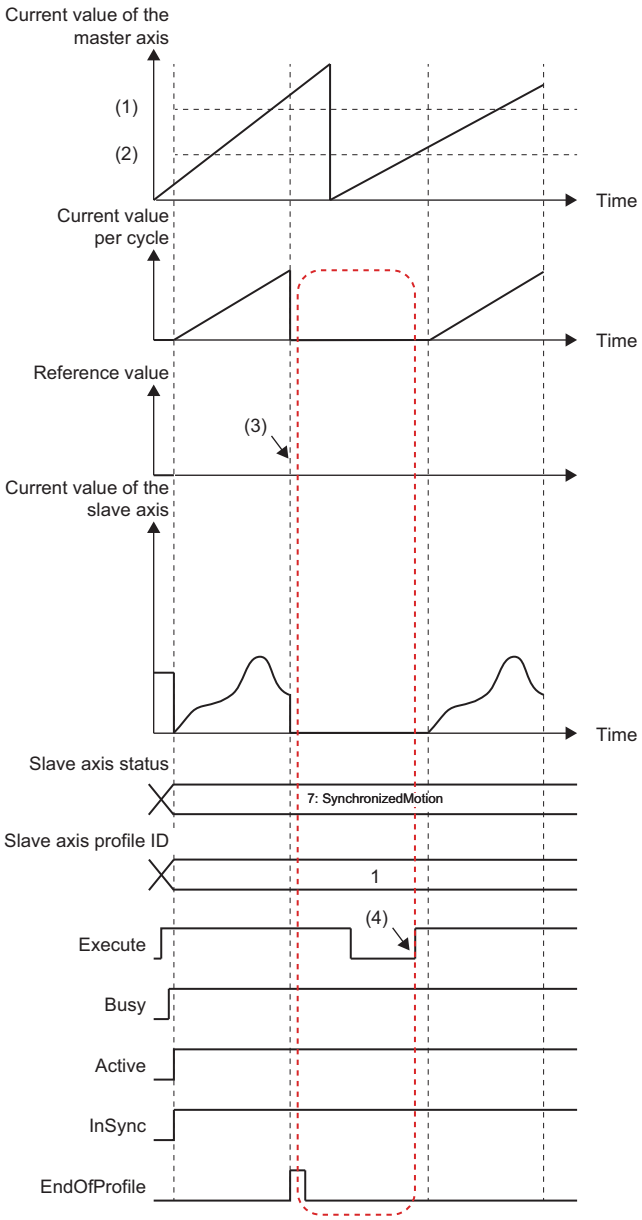
☞ Page 813 Monitor data during cam operation

■When Specifying operation after one cycle operation (Options (Options): bit 16) is "0: Complete"

Synchronization status is canceled after one cycle. When Execution command (Execute) is started again, the status enters Synchronization status and the control of MC_CamIn (Cam Operation Start) starts.

When Slave axis absolute coordinate (SlaveAbsolute) is "FALSE: Relative coordinate"	When Slave axis absolute coordinate (SlaveAbsolute) is "TRUE: Absolute coordinate"
	
(1): Master axis synchronization start position + Master axis follow-up distance (2): Master axis synchronization start position (3): The value is calculated from the current value per cycle that is started based on the set value where InSync becomes TRUE. (4): Synchronization status is canceled at the end of one cycle.	(1): Master axis synchronization start position + Master axis follow-up distance (2): Master axis synchronization start position (3): The initial value of the reference value is 0.0.



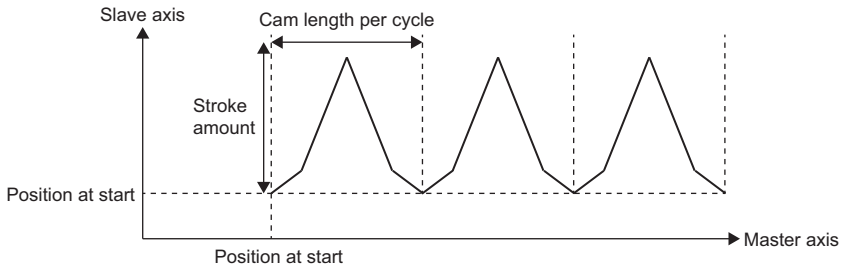


■When Specifying operation after one cycle operation (Options (Options): bit 16) is "1: Wait for restart"

Synchronization status is maintained even after one cycle. When Execution command (Execute) is started again, updating of the current value per cycle (InputPerCycle), reference value (Reference), and output value (OutputData) is started regardless of the Start mode (StartMode) settings.

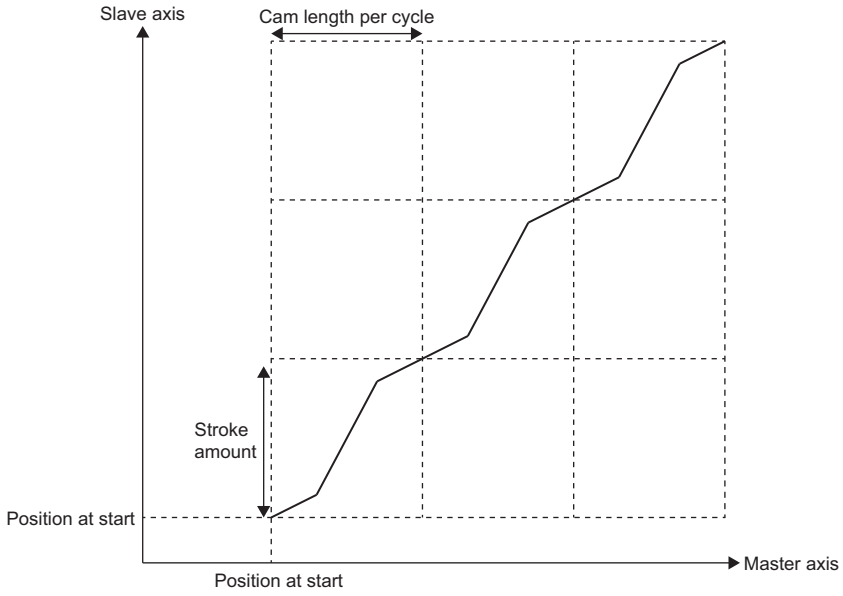
Input stop cause to the slave axis to cancel synchronization status.

While waiting for a restart after one cycle has completed, even when values of input labels where continuous update is possible are changed, any input information will not be imported until Execution command (Execute) is restarted.



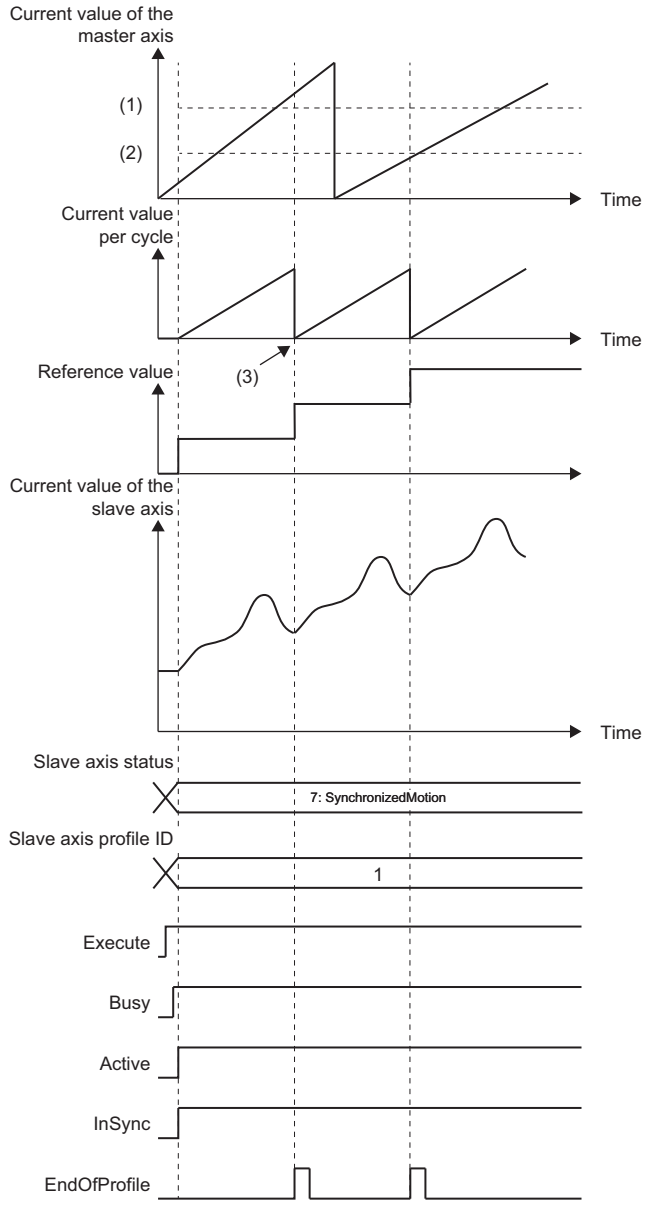
While waiting for a restart after one cycle has completed, if a change to the current value per cycle is executed, this will be valid from the next cycle.

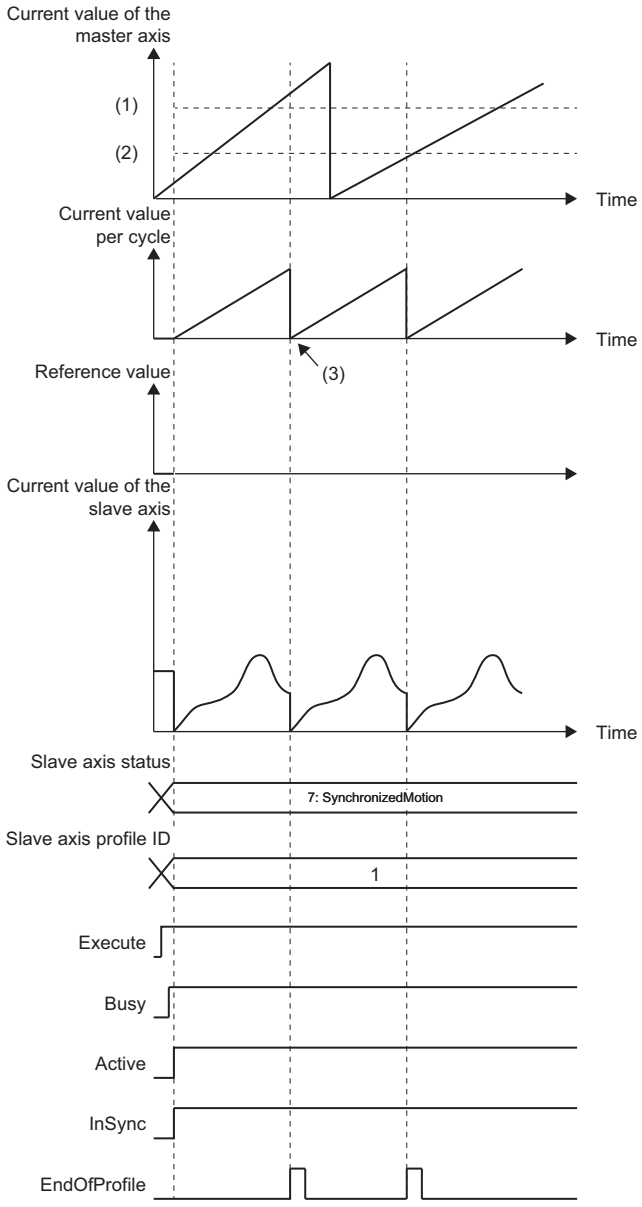
When Slave axis absolute coordinate (SlaveAbsolute) is "FALSE: Relative coordinate"	When Slave axis absolute coordinate (SlaveAbsolute) is "TRUE: Absolute coordinate"
	
(1): Master axis synchronization start position + Master axis follow-up distance (2): Master axis synchronization start position (3): The status after one cycle is maintained. (4): Execute is started again.	(1): Master axis synchronization start position + Master axis follow-up distance (2): Master axis synchronization start position (3): The status after one cycle is maintained. (4): Execute is started again.



• TRUE: Periodic

Cam table execution is repeated continuously. When the positions of Slave axis (Slave) at the cam table start point are the same each time by repeating, cam is operated as a two-way cam. When the set positions at the start point and the end point are different, cam is operated as a feed cam.





■Two-way cam operation

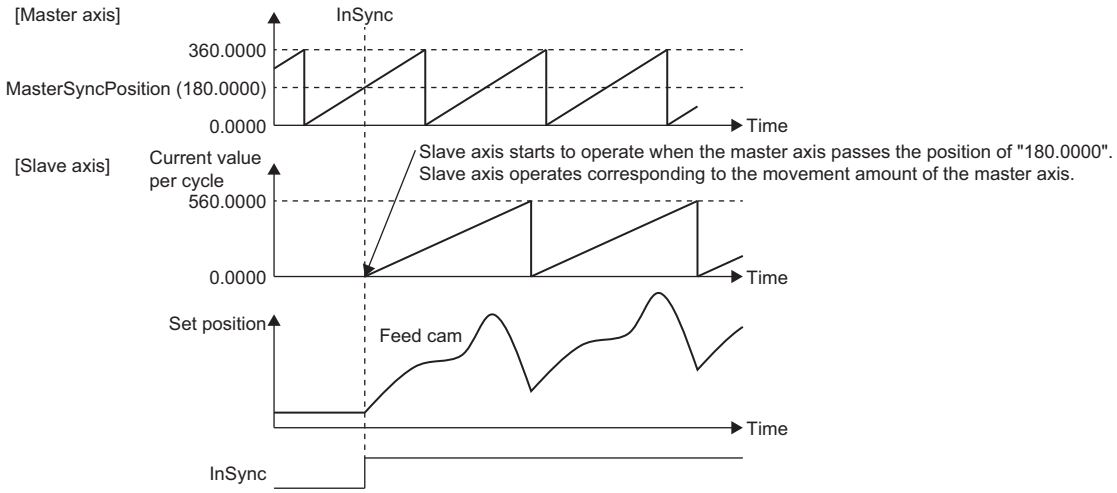
■Feed cam operation

The operation image of the repetitive operation is as shown below.

When Slave axis absolute coordinate (SlaveAbsolute) is "FALSE: Relative coordinate"	When Slave axis absolute coordinate (SlaveAbsolute) is "TRUE: Absolute coordinate"
	
(1): Master axis synchronization start position + Master axis follow-up distance (2): Master axis synchronization start position (3): The status is maintained even after one cycle.	(1): Master axis synchronization start position + Master axis follow-up distance (2): Master axis synchronization start position (3): The status is maintained even after one cycle.

■Master axis absolute coordinate

The following explains the cam operation based on Master axis absolute coordinate (MasterAbsolute) set by MC_CamTableSelect (Cam Table Selection).



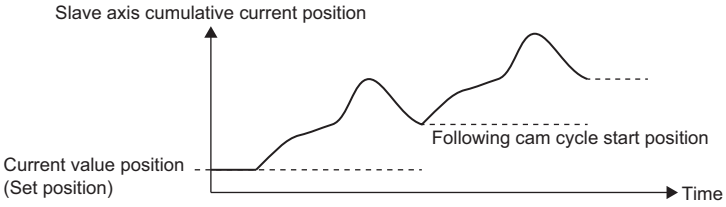
• "0: Relative coordinate" is specified to Master axis absolute coordinate (MasterAbsolute).

Master axis synchronization start position (MasterSyncPosition) becomes the start point of the cam table. When In synchronization (InSync) becomes TRUE, cam operation is executed corresponding to the relative movement amount of Master axis (Master). Cam operation is executed continuously, even when ring counters of Master axis (Master) and cam table are not matched.

Ex.

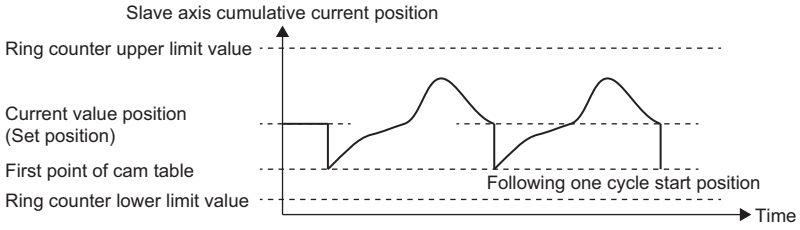
For the following settings.

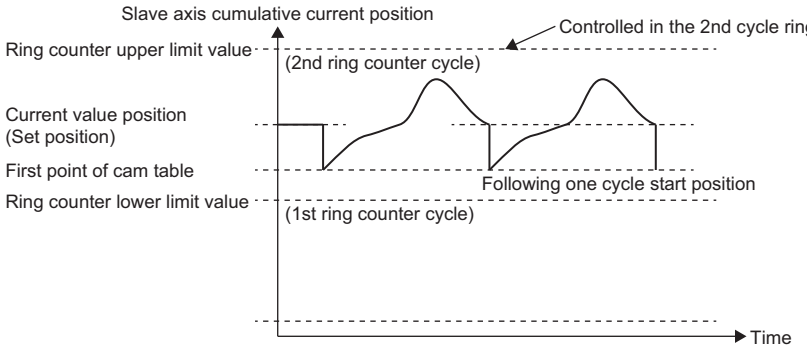
- Master axis: Ring counter of the current value: 0.0000 to 360.0000 [degrees]
- Master axis synchronization start position (MasterSyncPosition): 180.0000 [degrees]
- Cam: Cam length per cycle: 540.0000 [degrees]

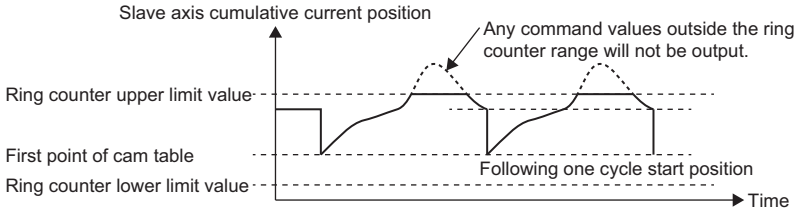


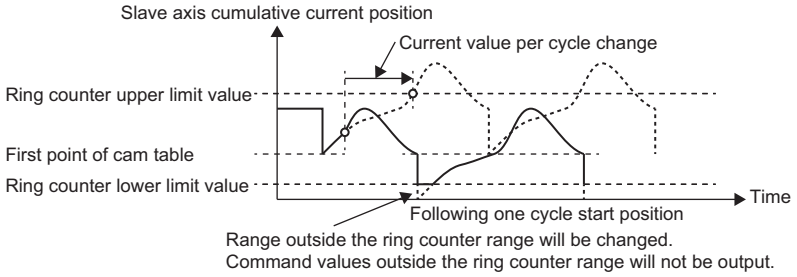
■Slave axis absolute coordinate

The following explains the operation based on Slave axis absolute coordinate (SlaveAbsolute) set by MC_CamTableSelect (Cam Table Selection).









• "0: Relative coordinate" is specified to Slave axis absolute coordinate (SlaveAbsolute).

When In synchronization (InSync) becomes TRUE, the slave axis starts the operation of the cam table from the current position (set position). When Periodic (Periodic) of the cam table is set to "TRUE: Periodic", after one cycle of the cam table has completed, the next cycle starts from the stroke position (set position) where the last cycle completed.

• "1: Absolute coordinate" is specified to Slave axis absolute coordinate (SlaveAbsolute).

The cam is operated within the ring counter range including current values of Slave axis (Slave) at the point when In synchronization (InSync) becomes TRUE. The command is output in one operation cycle to return the set position of Slave axis (Slave) to the start point of the cam table when In synchronization (InSync) and Cam cycle completion (EndOfProfile) become TRUE. If the command at this time is too large, the position command and velocity command to the drive unit also become too large, causing the servo alarm [AL. 035_Command frequency error] for the MR-J5(W)-G. Values are output so that the set position of Slave axis (Slave) is always within the ring counter range.

Status	Operation
When the stroke range is within the ring counter range of slave axis	
When the stroke range is within the ring counter range of slave axis (Cam started on the second cycle)	
When the stroke range is outside the ring counter range of the slave axis	
When current value per cycle is changed	When changing the current value per cycle, to compensate the Reference value (Reference) so that the Slave axis (Slave) does not operate, any range outside of the ring counter range will be changed. When Slave axis (Slave) has moved and the current value per cycle has changed, change Master axis offset (MasterOffset). 

■Length per cycle

Set the input amount that is required for one cycle. For details, refer to the following.

☞ Page 813 Current value per cycle (InputPerCycle)

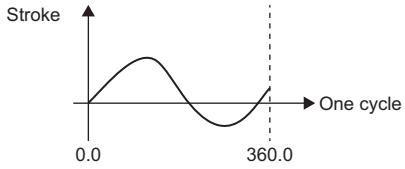
■Stroke amount

Set the stroke amount corresponding to its ratio 100%. For details, refer to the following.

☞ Page 814 Output value (MC_CamIn.OutputData)

■Start point and Initial stroke amount

Start point used for cam operation and the Initial stroke amount will differ depending on the interpolation method specification.

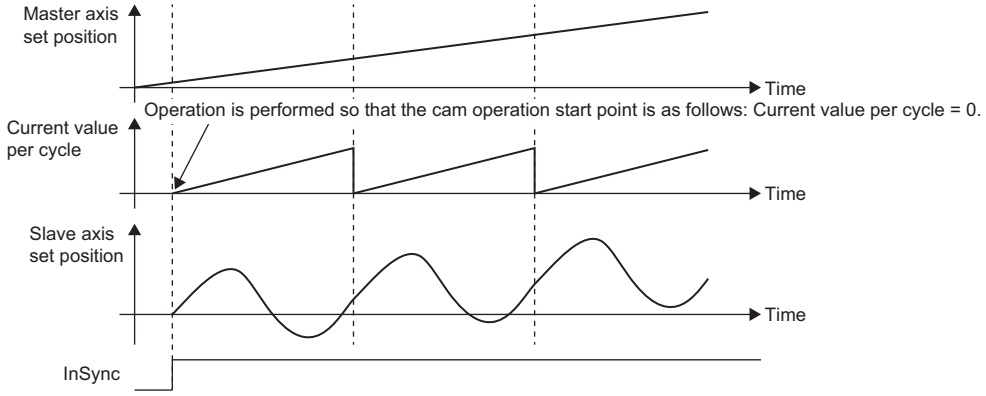


Interpolation method specification	Cam operation start point	Initial stroke amount for cam operation
0: Linear interpolation	Input value of the cam table first point	Output value of the cam table first point
1: Section interpolation	Start point (StartPoint) of the cam table first point	Initial stroke amount (StartStroke) of the cam table
2: Spline interpolation		

- Cam operation start point

Operates so that Current value per cycle (InputPerCycle) is "0".

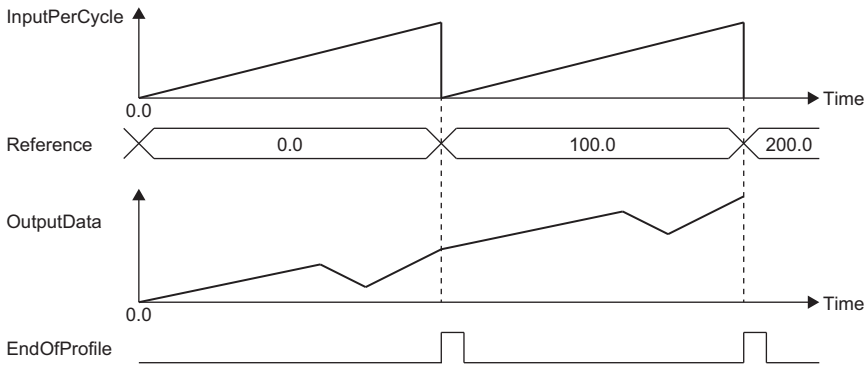
- Cam table



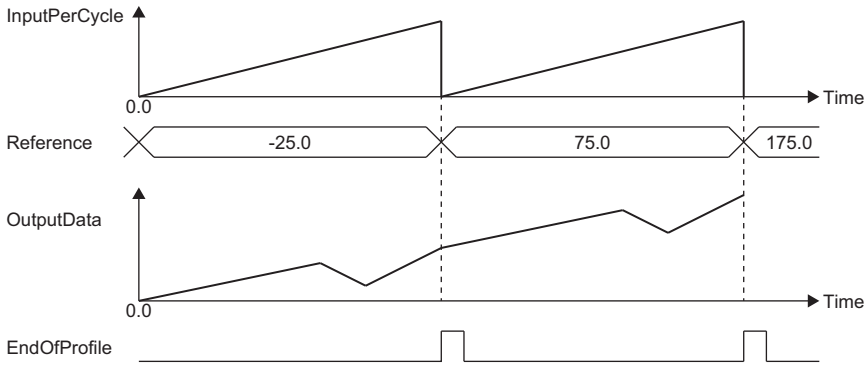
■Cam (1) (Cam operation start point "0.0")

- Interpolation method: Section interpolation
- Length per cycle: 360.0
- Start point: 0.0
- Initial stroke amount: 0.0

- Cam operation



The operation is as follows.



• Initial stroke amount for cam operation

Operates so that it becomes the Output value (OutputData) at the start of synchronization. Because the initial stroke amount of the cam operation stops the slave axis from operating, the initial stroke amount is subtracted from Reference value (Reference).

■When Initial stroke amount of cam operation is "0.0"

■Initial stroke amount of cam operation is "25.0"

Monitor data during cam operation

During MC_CamIn (Cam Operation Start) control, the current value per cycle, the reference value, and the output value can be monitored through Current value per cycle (InputPerCycle), Reference value (Reference), and Output value (OutputData).

Name	Variable name	Data type	Refresh cycle
Current value per cycle	InputPerCycle	LREAL	Execution cycle of POU (abbreviation for Program Organization Unit) that calls the FB
Reference value	Reference	LREAL	
Output value	OutputData	LREAL	
Instance ID	InstanceID	WORD(UINT)	

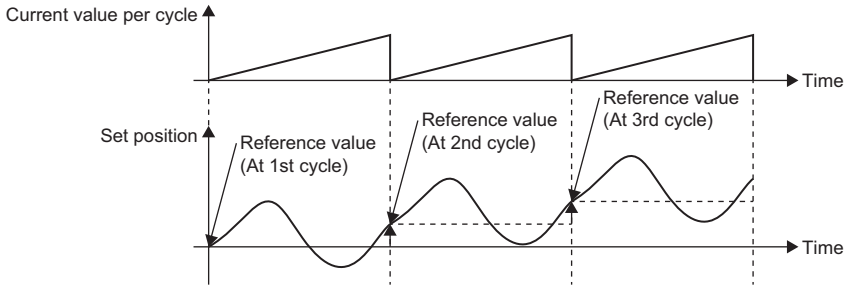
■Current value per cycle (InputPerCycle)

The initial value is "0".

The movement amount of Master axis (Master) is reflected after Controlling (Active) turns TRUE as follows.

Current value per cycle = (Cumulative movement amount of the master axis - Master axis offset + Current value change per cycle) MOD Length per cycle

The monitor value range is "0 ≤ Current value per cycle (MC_CamIn.InputPerCycle) < (Length per cycle × Master axis scaling)"



■Reference value (Reference)

When MC_CamIn (Cam Operation Start) is executed, the value is calculated from the cam position for start (current value per cycle) based on the set position where In synchronization (InSync) becomes TRUE. The formula for initial value is as follows because the Initial stroke amount during cam table is subtracted.

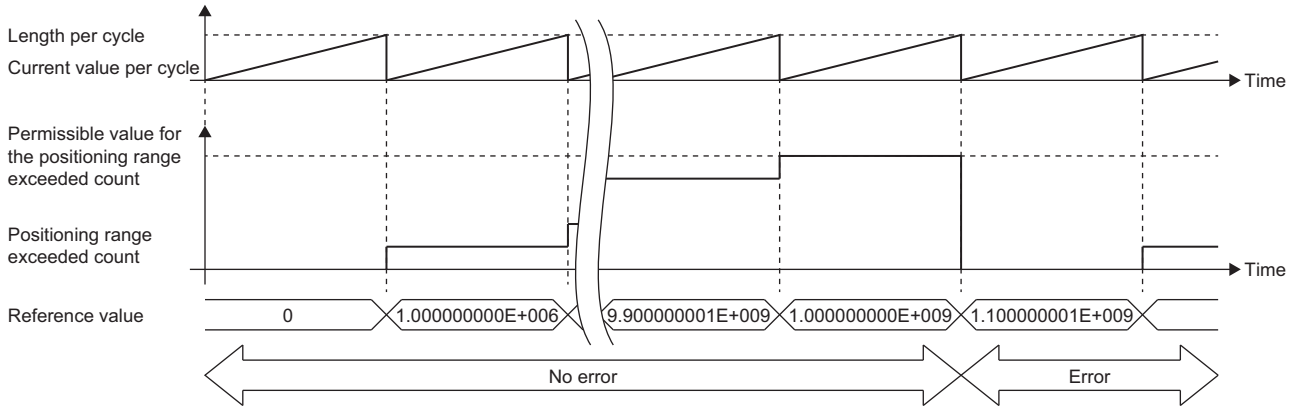
Slave axis absolute coordinate (SlaveAbsolute)	Calculation formula
FALSE: Relative coordinate	Reference value = Slave axis position when synchronization starts - (Stroke value based on the cam position (current value per cycle) when In Synchronization (InSync) changes to TRUE + the initial stroke amount) × Slave axis scaling
TRUE: Absolute coordinate	Reference value = The set position corresponding to the cumulative current position being 0 when In synchronization (InSync) changes to TRUE.

When Two-way cam operation, or Slave axis absolute coordinate (SlaveAbsolute) is "TRUE: Absolute coordinate", the reference value is not updated. When Slave axis absolute coordinate (SlaveAbsolute) is "FALSE: Relative coordinate" with feed cam operation, the reference value is calculated as shown below.

Calculation formula
Reference value = (Original reference value + (Stroke value at the last point - Stroke value at the first point) × Slave axis scaling)

Reference value is updated at the following timing

Update timing	Calculation formula of reference value
When Current value per cycle (InputPerCycle) passes the last point of cam table in the address increasing direction	Original reference value + ((Stroke value at the last point - Stroke value at the 1st point) × Slave axis scaling)
When Current value per cycle (InputPerCycle) passes the first point of cam table in the address decreasing direction	Original reference value - ((Stroke value at the last point - Stroke value at the 1st point) × Slave axis scaling)
When changing current value per cycle (MCv_ChangeCycle (Current Value Change per Cycle) completion (Done) is TRUE.)	Original reference value - (Stroke value corresponding to current value per cycle after change × Slave axis scaling)



Restriction

<For the reference value error>

Any of the following operation may cause the error of reference value.

• Condition 1: If the number of times that TRUE is output for Cam cycle completion (EndOfProfile) exceeds the permissible value after In synchronization (InSync) becomes TRUE with feed cam

While an error does not occur if the positioning range exceeded count is less than the permissible value for the positioning range exceeded count, an error may occur if the permissible value is exceeded. (The operation is maintained regardless of the operation error occurrence or not.)

• Condition 2: When the following control parameter includes a decimal with feed cam

(1) Stroke value at the last point - Stroke value at the first point

(2) Slave axis coefficient

• Condition 3: When changing current value per cycle is repeated in relative specification

When the reference value error becomes too large, clear the synchronization status or reset it by executing current value change of absolute position specification.

For the error, refer to the following.

☞ Page 496 Positioning Range

The permissible value for the positioning range exceeded count is a variable value calculated with the following formula.

Permissible value for the positioning range exceeded count = Limit value for the positioning range exceeded count / ((Output value at the last point - Output value at the 1st point) /slave scaling)

* The limit value for the positioning range exceeded count is the upper limit value of the positioning range, "10000000000".

(Example)

When the output value at the 1st point is "0", the output value at the last point is "1000000", and the output coefficient is "10", the permissible value for the positioning range exceeded count becomes "100000".

The monitor value range is shown below.

• Ring counter lower limit value of the slave axis ≤ Reference value < Ring counter upper limit value of the slave axis

■Output value (MC_CamIn.OutputData)

The initial value is the initial stroke amount during cam table. For details, refer to the following.

☞ Page 811 Start point and Initial stroke amount

While In synchronization (InSync) is TRUE, the value is calculated as shown below.

Output value = Reference value + ((Stroke amount × Stroke ratio corresponding to the current value per cycle) × Slave axis scaling) + Slave axis offset

or

Output value = Reference value + (Output value corresponding to the current value per cycle) × Slave axis scaling) + Slave axis offset

The monitor value range is shown below.

• Ring counter lower limit value of the slave axis ≤ Output value < Ring counter upper limit value of the slave axis

Precautions

- Changing Master axis offset (MasterOffset), Slave axis offset (SlaveOffset), Master axis scaling (MasterScaling), Slave axis scaling (SlaveScaling), and Cam table ID (CamTableID) may give impact to the machine because the slave axis moves suddenly at the start of control or at control change. It is important to carefully check the setting values and the change timing.
- When the axis being cam controlled is monitored with the engineering tool, the position, velocity, and other units are based on the unit setting of the axis. Units for the length per cycle and stroke amount set in the operation profile data are not used.

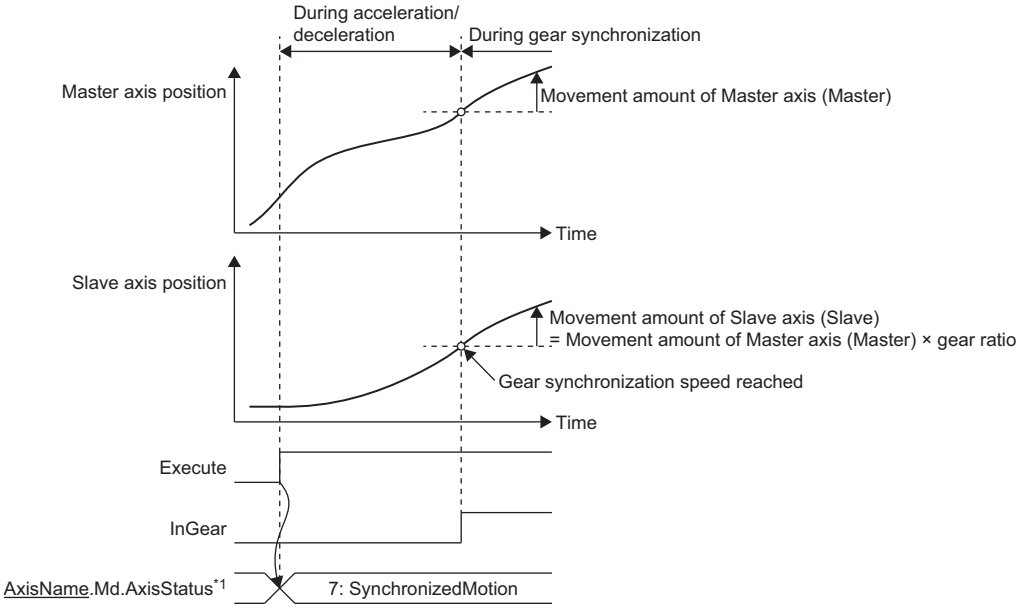
31.8 Gear Operation

This function sets the speed ratio between the master axis and the slave axis, and starts gear operation.

Relevant FB

For details on motion control FBs, refer to the following.

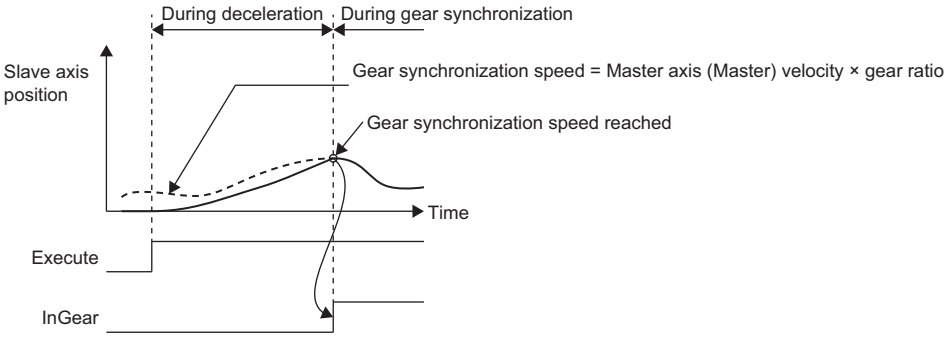
MELSEC MX Controller MX-R Model Programming Manual



Motion control FB	Name	Description
MC_GearIn	Gear operation start	Gear operation starts according to the specified gear ratio.

Control details

In the MC_GearIn (Gear Operation Start), Gear ratio numerator (RatioNumerator), Gear ratio denominator (RatioDenominator), Master axis data source selection (MasterValueSource), Acceleration (Acceleration), Deceleration (Deceleration), Jerk (Jerk), and Buffer mode (BufferMode) are set and the gear operation starts.



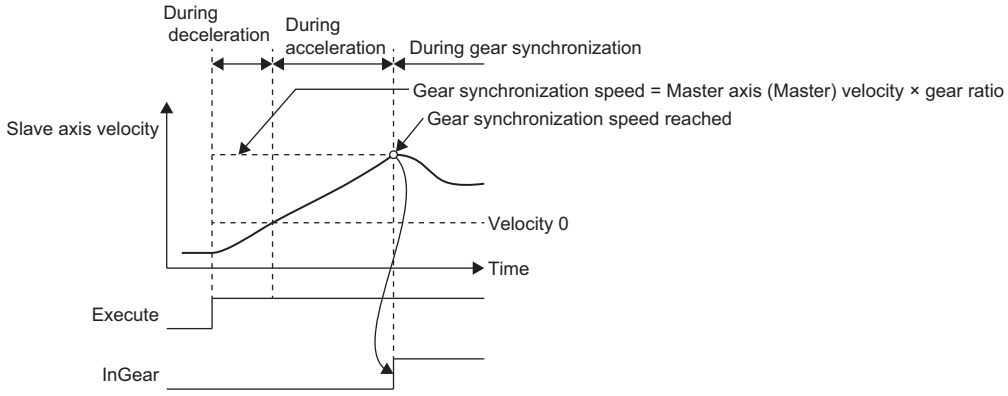
To stop the operation, execute MC_Stop (Forced Stop).

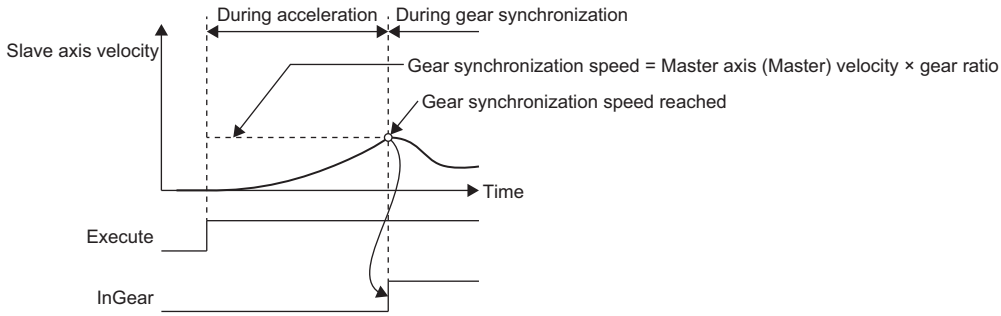
After executing this FB, Slave axis (Slave) performs acceleration/deceleration until reaching the gear synchronization speed, the value of which is the velocity of Master axis (Master) converted by the gear ratio. After reaching the gear synchronization speed, Gear ratio reached (InGear) becomes TRUE, and Slave axis (Slave) is controlled using a velocity equal to the velocity of Master axis (Master) converted by the gear ratio.

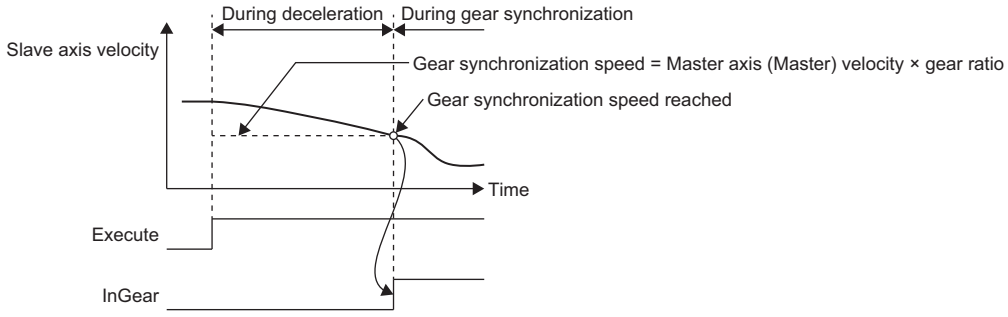
*1 This is the state of Slave axis (Slave).

- When the speed of Master axis (Master) is changed during acceleration/deceleration, the gear synchronization speed is also updated.

Acceleration/deceleration until reaching the gear synchronization speed







- The acceleration/deceleration method for MC_GearIn (Gear Operation Start) is the acceleration/deceleration specification method.

For details on the operation of the acceleration/deceleration specification method, refer to the following.

☞ Page 1078 Acceleration/Deceleration Processing Function

- Depending on the velocity of Slave axis (Slave) and the gear synchronization speed at operation start, one of the following four types of acceleration/deceleration is performed.

The type of acceleration/deceleration will not change even if the gear synchronization speed is updated during the acceleration/deceleration.

Velocity of Slave axis (Slave) and gear synchronization speed	Acceleration/deceleration operation
Velocity of Slave axis (Slave) < 0 < Gear synchronization speed or Velocity of Slave axis (Slave) > 0 > Gear synchronization speed	Deceleration is performed to velocity 0, then acceleration is performed from velocity 0 to the gear synchronization speed. 
Velocity of Slave axis (Slave) (Absolute value) < Gear synchronization speed (Absolute value)	Acceleration is performed until reaching the gear synchronization speed. 
Velocity of Slave axis (Slave) (Absolute value) > Gear synchronization speed (Absolute value)	Deceleration is performed until reaching the gear synchronization speed. 
Velocity of Slave axis (Slave) = Gear synchronization speed	Acceleration/deceleration is not performed. After operation is started, Gear ratio reached (InGear) becomes TRUE immediately and Slave axis (Slave) is controlled using a velocity equal to the velocity of Master axis (Master) converted by the gear ratio.

Precautions

- When the gear ratio is changed, the speed of the slave axis is changed directly. To smooth the speed change, use with MCv_SmoothingFilter (Smoothing Filter).
- When the velocity of Master axis (Master) after conversion exceeds the acceleration/deceleration upper limit value during acceleration/deceleration operation, Acceleration Time Limit Over Warning (event code: 00D04H) or Deceleration Time Limit Over Warning (event code: 00D05H) will occur, the acceleration/deceleration operation is stopped, and the operation is restarted and continued at the velocity in the warning detection.

If the above warning occurs, adjust and set Master axis (Master) speed after conversion, Acceleration (Acceleration), or Deceleration (Deceleration) to not exceed the acceleration/deceleration upper limit value to restart the acceleration/deceleration operation.

31.9 Addition/Subtraction Positioning

This function combines the movement amount of two axes and transmits.

Relevant FB

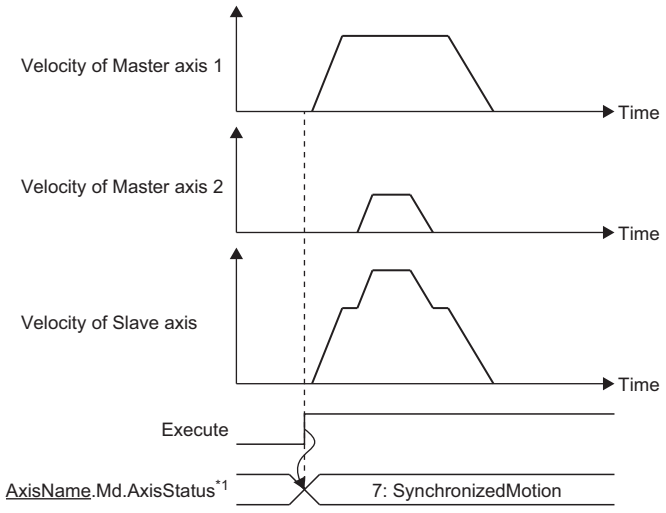
For details on motion control FBs, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

Motion control FB	Name	Description
MC_CombineAxes	Addition/subtraction positioning	The value obtained by adding or subtracting the movement amount of the specified two master axes is set as the set position, and the positioning is executed.

Control details

In MC_CombineAxes (Addition/Subtraction Positioning), Addition/subtraction method selection (CombineMode), Master axis 1 gear ratio numerator (GearRatioNumeratorM1), Master axis 1 gear ratio denominator (GearRatioDenominatorM1), Master axis 2 gear ratio numerator (GearRatioNumeratorM2), and Master axis 2 gear ratio denominator (GearRatioDenominatorM2), Master axis 1 data source selection (MasterValueSourceM1), Master axis 2 data source selection (MasterValueSourceM2), and Buffer mode (BufferMode) are set and the addition/subtraction positioning is executed.

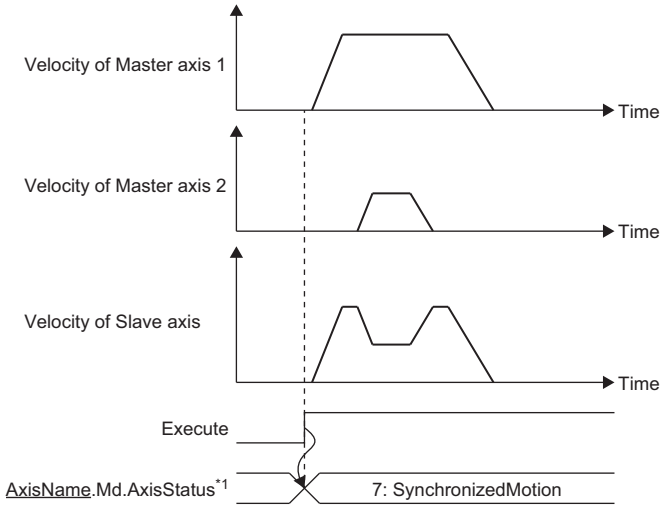


To stop the operation, execute MC_Stop (Forced Stop).

The movement amount of Master axis 1 (Master1) and Master axis 2 (Master2) is combined. Also, gear ratio can be set to each master axis.

Regarding the combined movement amount, addition or subtraction is performed on the value regardless of the unit of Master axis 1 (Master1) and Master axis 2 (Master2).

When CombineMode is set to "0: Add positions of 2 input axes (mcAddAxes)"



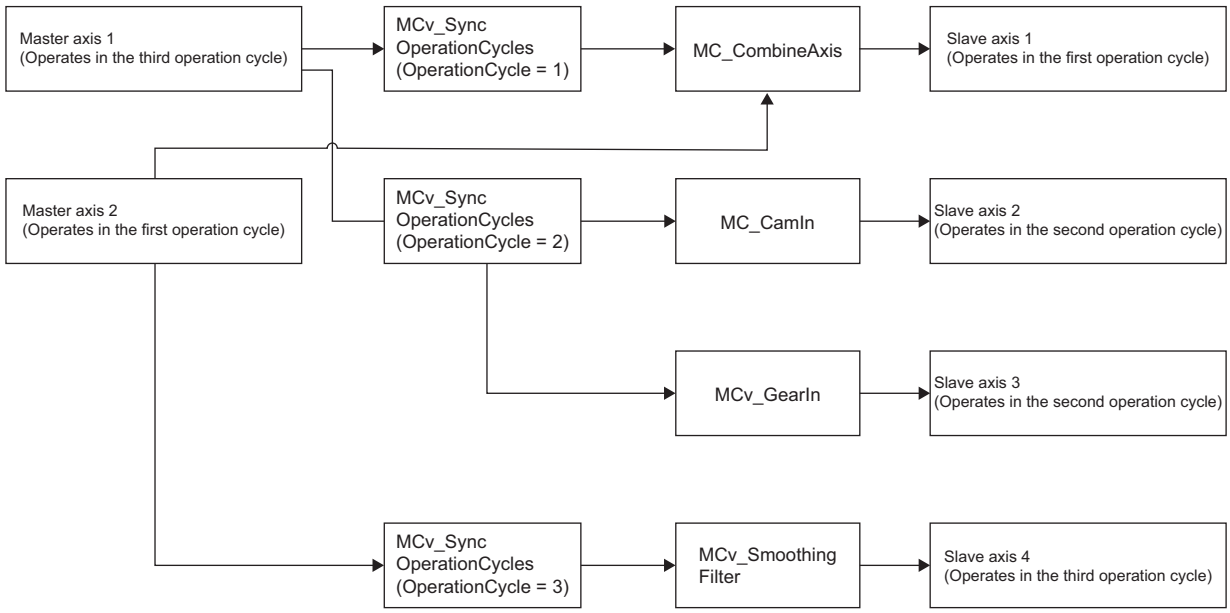
Movement amount of Slave axis (Slave) = Movement amount of Master axis 1 (Master1) + Master axis 2 (Master2)

*1 This is the state of Slave axis (Slave).

When CombineMode is set to "1: Subtract positions of 2 input axes (mcSubAxes)"

Movement amount of Slave axis (Slave) = Movement amount of Master axis 1 (Master1) - Master axis 2 (Master2)

*1 This is the state of Slave axis (Slave).

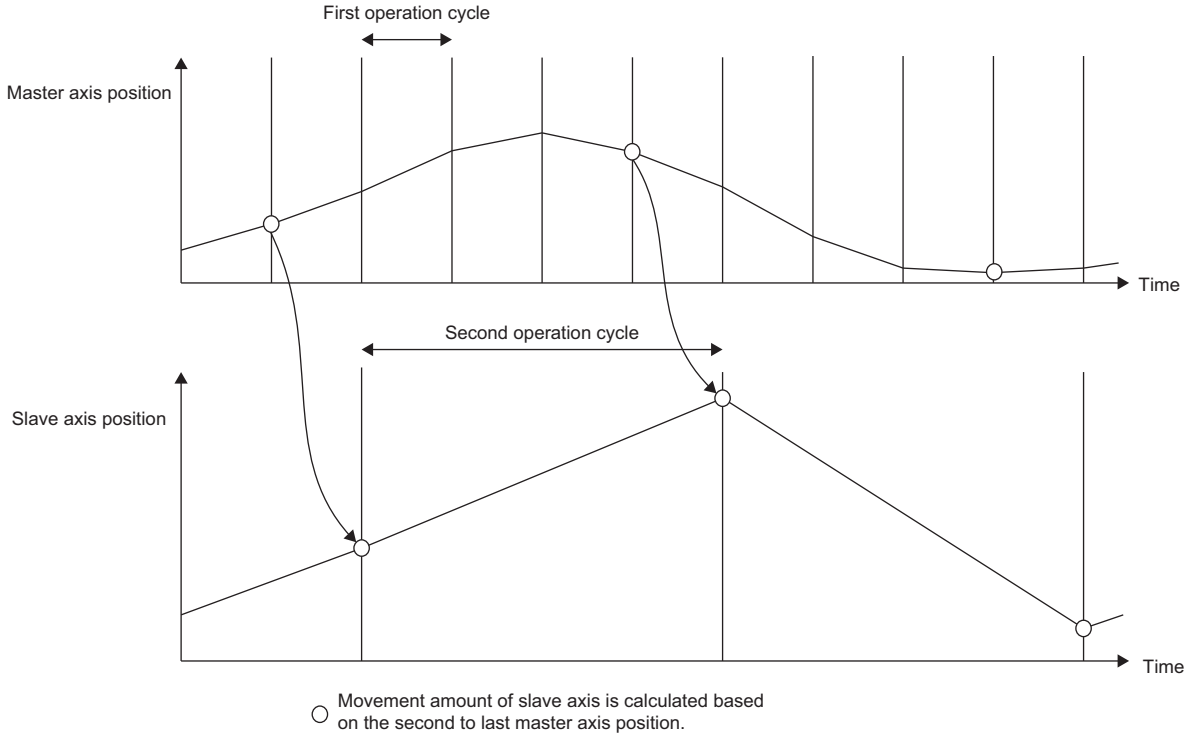


31.10 Precautions

When the operation cycle coexistence function is used, the following restrictions are applied if the control operation cycle settings for the master axis and slave axis are different.

- The control operation cycle of the master axis must be synchronized with that of the slave axis using Synchronize Control Operation Cycle (MCv_SyncOperationCycles) in addition to the synchronous control FB. If synchronous control is performed without using Synchronize Control Operation Cycle (MCv_SyncOperationCycles), Operation cycle mismatch (error code: 1B29H) occurs.
- Set the control operation cycle of the master axis to the Axis information (Axis) of Synchronize Control Operation Cycle (MCv_SyncOperationCycles), and the control operation cycle of the slave axis to Control Operation Cycle (OperationCycle). If the Control Operation Cycle (OperationCycle) settings and the control operation cycle of the slave axis are different, Operation cycle mismatch (error code: 1B29H) will occur when synchronous control is started.

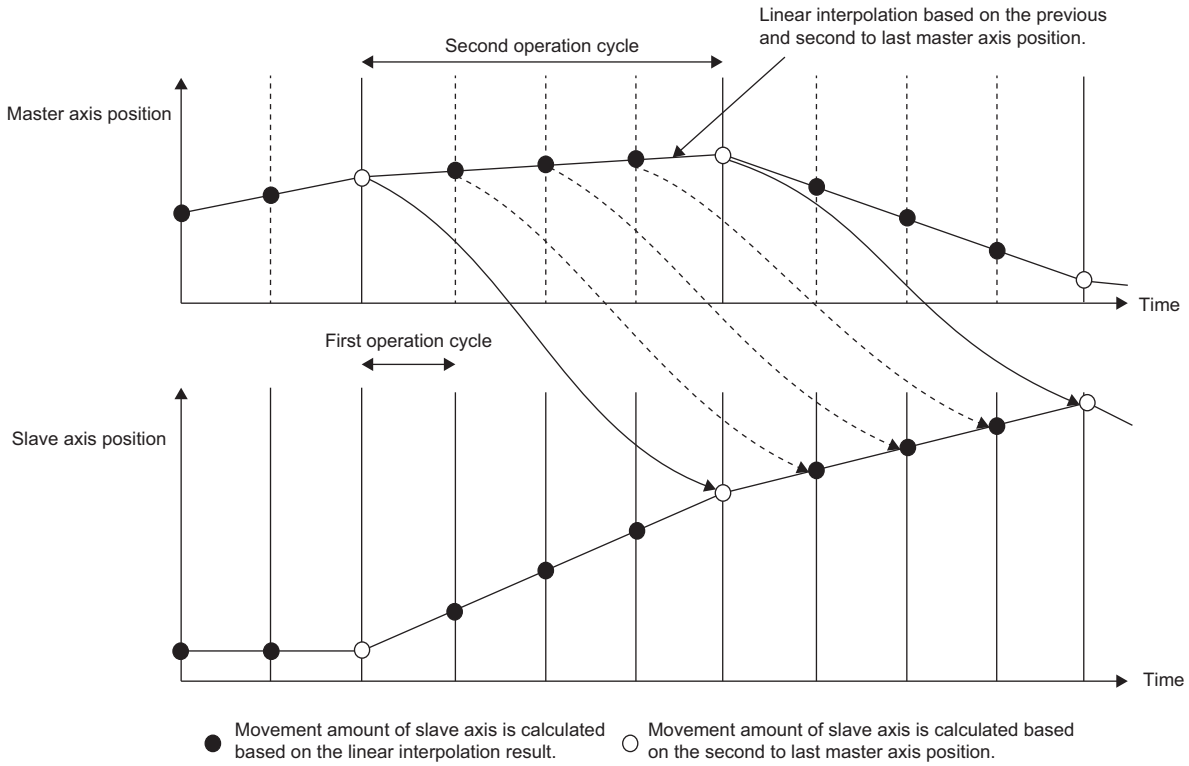
Ex.



For synchronous control between the axes with different control operation cycles

- Enable Synchronize Control Operation Cycle (MCv_SyncOperationCycles) of the master axis before starting synchronous control. If synchronous control is started before Synchronize Control Operation Cycle (MCv_SyncOperationCycles) is enabled, the input values of the master axis will not be updated.
- Do not switch the enable/disable state of Synchronize Control Operation Cycle (MCv_SyncOperationCycles) of the master axis during synchronous control. If switched, the slave axis may stop suddenly or move abruptly. When not In synchronous control, Synchronize Control Operation Cycle (MCv_SyncOperationCycles) of the master axis can be disabled.
- Master axis data source selection (MasterValueSource) of the synchronous control FB cannot be set to "101: Latest Set Value (mcLatestSetValue)" or "102: Latest Actual Value (mcLatestActualValue)". Either set "1: Set Value (mcSetValue)" or "2: Actual Value (mcActualValue)". If any other value is set, Out of master axis data source range (error code: 1AB6H) occurs.
- When the synchronous control FB with axes having different operation cycles as input and output is connected, there will be a significant delay until the input of the master axis is transmitted to the output of the slave axis.
- If the operation cycle of the slave axis is slower than that of the master axis, the movement amount of the slave axis is calculated based on the operation result of the master axis from the previous cycle. The movement amount of the slave axis will be calculated as the time interval of the slower operation cycle.

Ex.



When MC_GearIn (Gear Operation Start) is executed

- If the operation cycle of the slave axis is faster than that of the master axis, the movement amount of the slave axis is calculated based on the operation result of the master axis from the previous cycle and the cycle before that. The movement amount of the slave axis will be calculated as the time interval of the faster operation cycle. To suppress the sudden speed changes in the slave axis, the operation results of the master axis are automatically linearly interpolated and input to the slave axis. There is a delay equivalent to the slower operation cycle before the input from the master axis is transmitted to the slave axis.

Ex.

When MC_GearIn (Gear Operation Start) is executed

Relevant add-ons

The following add-ons are required to use the synchronous control function.

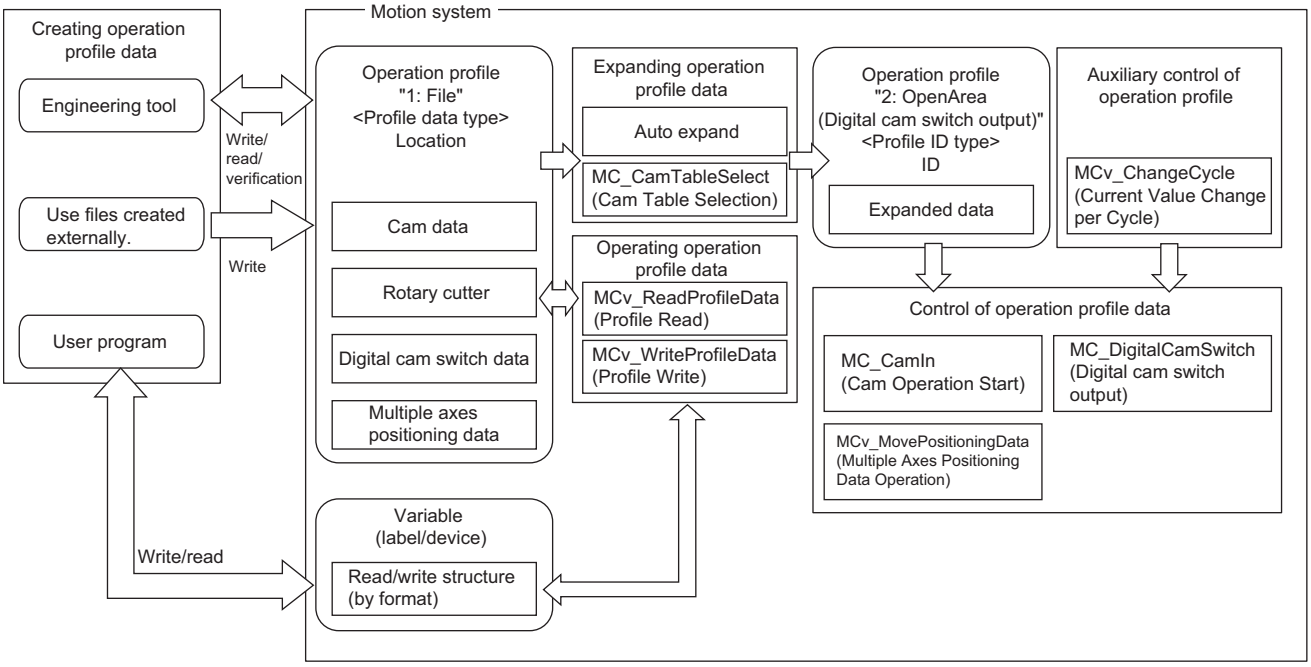
- ProfileControl
- MotionControl_Sync
- MotionEngine
- Axis
- MotionControl_General

32 OPERATION PROFILE DATA FUNCTION

This function performs opening profile for the cam and reading/writing for the cam.

32.1 Operation Profile Data

Waveform data used for control is collectively called operation profile data.
This section describes how to create and use operation profile data.



Operation of this function for each system status

○: Available, ×: Not available

System status	Operation availability
STOP	×
RUN	○
Moderate error	×
Major error	×

Overall block diagram

The following diagram shows the relevancy between the data from creating to using of operation profile data and the motion control FB about operation profile data used in various functions (e.g. the cam of single axis synchronous control).

Relevant variables

PROFILE_DATA

Variable/structure name	Name	Details
Location	Operation Profile Data Storage Location	Sets the file name and storage location of the operation profile data. FILE_LOCATION type
ID	Profile ID	Sets the number for the profile ID of the operation profile data. PROFILE_ID type

FILE_LOCATION

Variable/structure name	Name	Details
FileName	File Name	Specifies a file name. (63 characters including the extension can be set.)*1
Path	Folder Specification	Specifies the folder path in which the file is stored. (Up to 63 characters can be set.)*1*2

*1 Set a total of up to 127 characters (including null string) for File name (FileName) and Folder specification (Path).
*2 The root path when specifying the relative path is %CALC_PROFILE_ROOT%.

Point

- Make sure the folder path does not exceed the maximum number of characters for the folder path.
- Make sure the file name does not exceed the maximum number of characters for the file name.

PROFILE_ID

Variable/structure name	Name	Details
Number	Profile ID No.	Sets the Profile ID No. • 0 to 60000
StartIO	I/O number	Sets the I/O number.

INSTANCE_ID

Variable/structure name	Name	Details
Number	Instance ID No.	Sets the number for the instance ID

System Parameter Constant (MotionSystem.PrConst.)

Variable/structure name	Name	Details
ProfileRootDrive	Operation profile data root drive	Sets the drive to save the operation profile data.

Relevant FBs

For details on motion control FBs, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

Motion control FB	Name	Description
MC_CamTableSelect	Cam table selection	Stores the specified operation profile data (cam data) in the open area.
MCv_ReadProfileData	Profile read	Reads the specified operation profile data from the open area or the file.
MCv_WriteProfileData	Profile write	Writes the specified operation profile data to the open area or the file.
MCv_ChangeCycle	Current value change per cycle	Changes the current value per cycle of the specified operation profile data control FB.

Operation profile data types

For the function to use operation profile data, there is an operation profile data format that supports the corresponding function. The following shows operation profile data format and I/O data that can be used for each function.

Function (Operation profile data control)	Operation profile data format	Input data	Output data	Operation profile data open
Cam operation (MC_CamIn (Cam Operation Start))	Cam data Rotary cutter	Master axis position (selected with MC_SOURCE)	Slave axis position	Auto expand*1 Write operation profile data*2 MC_CamTableSelect (Cam Table Selection)
Multiple axes positioning data operation (MCv_MovePositioningData (Multiple Axes Positioning Data Operation))	Multiple axes positioning data	Positioning data No.	Set position of axes group configuration axis	Auto expand*1 Write operation profile data*2
Digital cam switch output (MC_DigitalCamSwitch (Digital Cam Switch Output))	Digital cam switch data	Any data	Digital output (0 or 1)	Auto expand*1 Write operation profile data*2
Advanced synchronous control (MCv_AdvancedSync (Advanced Synchronous Control))	Cam data Rotary cutter	Master axis position, sub input axis, sub axis position (selected with MC_SOURCE)	Slave axis position	Auto expand*1 Write operation profile data*2 MC_CamTableSelect (Cam Table Selection)
Advanced synchronous control current position per cycle calculation (MCv_AdvPositionPerCycleCalc (Advanced Synchronous Control Current Position Per Cycle Calculation))	Cam data Rotary cutter	• Ring counter upper limit • Cam start point • Length per cycle • Stroke amount • Current position per cycle • Cam reference position • Cam set position	Current position per cycle	Auto expand*1 Write operation profile data*2 MC_CamTableSelect (Cam Table Selection)
Advanced synchronous control cam set position calculation (MCv_AdvCamSetPositionCalc (Advanced Synchronous Control Cam Set Position Calculation))	Cam data Rotary cutter	• Ring counter upper limit • Cam start point • Length per cycle • Stroke amount • Current position per cycle • Cam reference position • Cam set position	Cam set position	Auto expand*1 Write operation profile data*2 MC_CamTableSelect (Cam Table Selection)

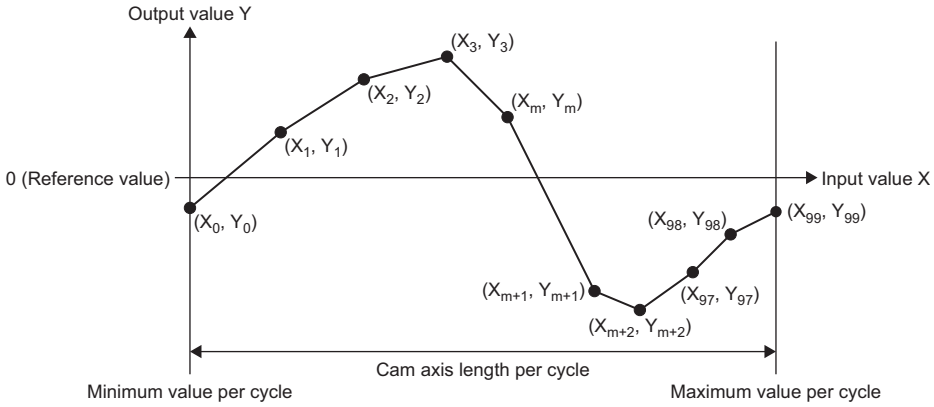
*1 When "Auto Expand" is set with the engineering tool.

*2 The profile is open by executing MCv_ReadProfileData (Profile Read) (file specification), followed by executing MCv_WriteProfileData (Profile Write) (open area specification).

Cam data

The relationship of output values (slave axis position) to input values (master axis position) is defined as the cam data.
The following interpolation methods can be selected as the cam data.

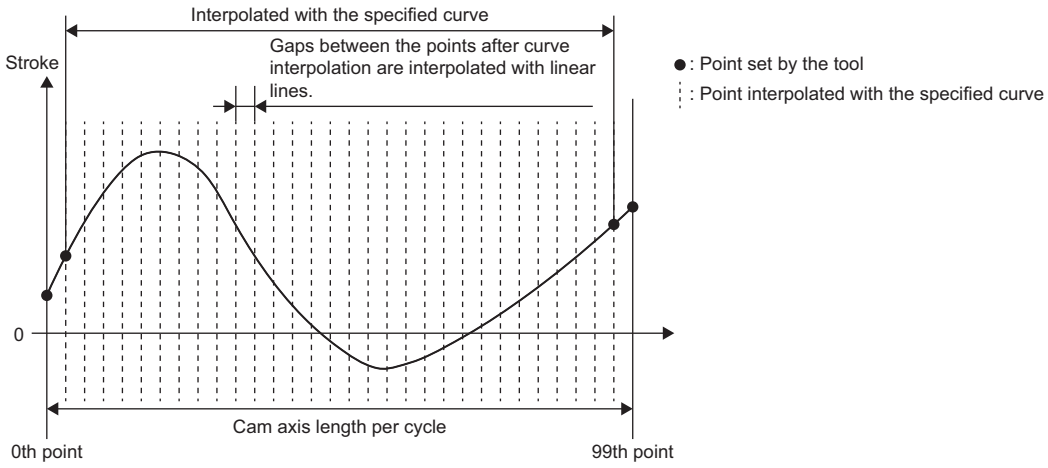
Interpolation method specification (Interpolate)	Description
0: Linear interpolation	Create cam data that specifies the input value (master axis position) and the output value (slave axis position) of each point and interpolates each point with straight lines.
1: Section interpolation	Create cam data that specifies the input value (master axis position), stroke, and cam curve type of each point and interpolates each point with the specified curve line.
2: Spline interpolation	Create cam data that specifies the input value (master axis position) and stroke of each point and performs spline interpolation of each point.



Required data for the setting differs depending on the selected interpolation method. Refer to the following.
◎: Necessary, ○: Optional, —: Unnecessary

Setting item		Interpolation method specification (Interpolate)		
		0: Linear interpolation	1: Section interpolation	2: Spline interpolation
Profile ID		○	○	○
Interpolation method specification		◎	◎	◎
Resolution/number of coordinates		◎	◎	◎
Input unit character string		○	○	○
Output unit character string		○	○	○
Start point		—	◎	◎
Initial stroke amount		—	◎	◎
Initial velocity		—	○	—
Initial acceleration		—	○	—
I/O data		◎	—	—
Parameter	Cam curve type	—	◎	—
	End point	—	◎	◎
	Stroke	—	◎	◎
	Curve applicable range	—	○	—
	Acceleration/ deceleration range compensation	—	○	—
	End point velocity	—	○	—
	End point acceleration	—	○	—
Length per cycle		◎	◎	◎
Minimum value per cycle		◎	—	—
Maximum value per cycle		◎	—	—
Time per cycle		—	○	—
Stroke amount		◎	◎	◎

■Interpolation method specification (Interpolate)



- 0: Linear interpolation

  The stroke data of each point data that is defined for a cam curve per cycle with two or more points (data of a pair of current value per cycle and stroke) is opened in the open area.

- 1: Section interpolation

  Gaps between the points are interpolated with the specified curve, and the stroke data that is defined after equally dividing a cam curve per cycle by points of the cam resolution (data of a pair of current value per cycle and stroke) is opened in the open area.

Point

If the number of I/O data is not enough for the set resolution, cam data that is equally divided after interpolating the data in shortage according to the line set by the curve specification will be created.

- 2: Spline interpolation

  Gaps between the points are spline interpolated, and the stroke data that is defined after equally dividing a cam curve per cycle by points of the cam resolution (data of a pair of current value per cycle and stroke) is opened in the open area.

■Profile ID

It is a unique ID assigned by an open instruction.

The ID opened by the MC_CamTableSelect (Cam Table Selection) can be used in the control instruction (MC_CamIn (Cam Operation Start)) as the MC_CAM_ID type. ID can be specified with an arbitrary No.

■Resolution/number of coordinates

Set the number of divisions for a cam curve for one cycle.

Set the number of data including the 0th point.

■Input/output unit character string

Set a unit of the input/output data with an arbitrary character string.

It is handled as a [pulse] when it is omitted. Also, when "%" is specified in the output unit character string, the control that the cam stroke amount is 100% is carried out.

Point

When a unit other than "%" is specified, it is not used in the control. It is used only in monitoring.

■Start point

Set "0.0".

When a value other than "0.0" is set, Operation profile data incorrect (error code: 1B8FH) occurs.

■Initial stroke amount

Set the stroke amount for the start point.

When the output unit character string is "%", it will be a value corresponding to the 100% of stroke ratio.

■Initial velocity/End point velocity

Set the velocity at the start point/end point.

Use when cam curve type is set to 5th Curve (Adj.).

The unit for setting value is [pulse/s] when output unit string is [pulse].

The unit for setting value is [output unit character string/min] when output unit string is other than [pulse].

Ex.

When output unit string is [degree]

The unit for setting value is [degree/min].

■Initial acceleration/End acceleration

Set the acceleration at the start point/end point.

Use when cam curve type is set to 5th Curve (Adj.).

The unit for setting value is [pulse/s^2] when output unit string is [pulse].

The unit for setting value is [output unit string/min^2] when output unit string is other than [pulse].

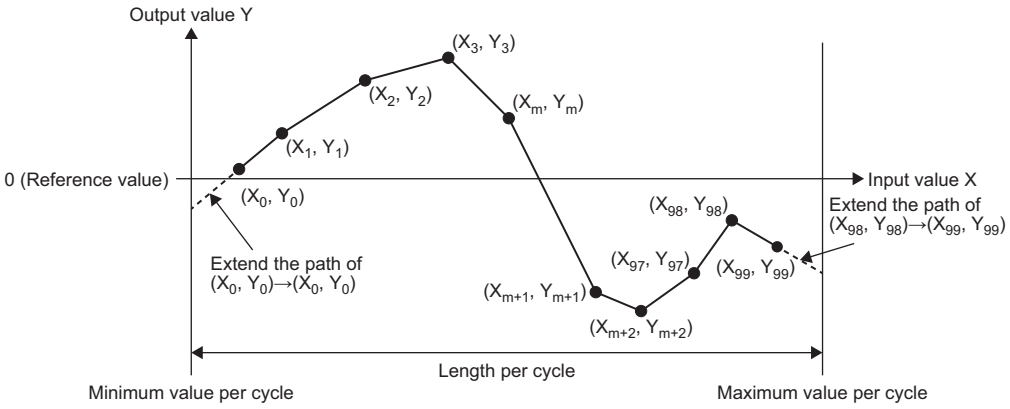
Ex.

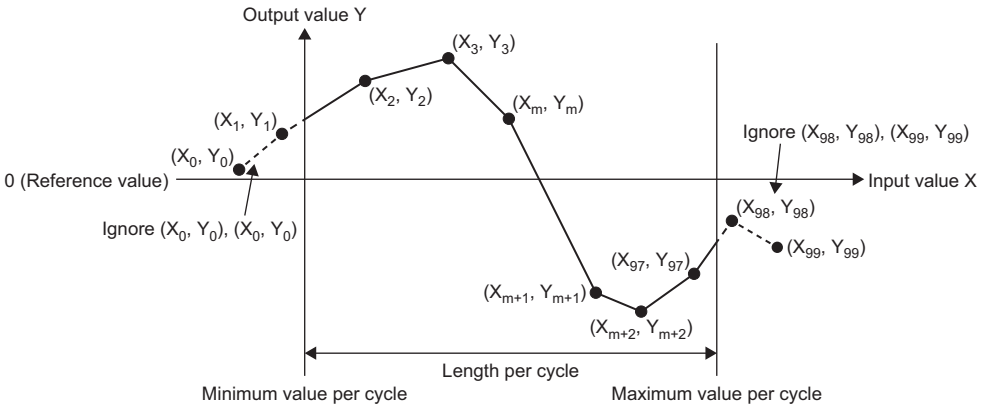
When output unit string is [degree]

The unit for setting value is [degree/min^2].

■Length per cycle

Set the input amount that is required for one cycle.





■Maximum value per cycle/Minimum value per cycle

Set the maximum/minimum value per cycle.

It is valid only when Interpolation Method Specification (Interpolate) is "0: Linear Interpolation".

Set "0" to minimum value per cycle. When a value other than "0" is set, Operation profile data incorrect (error code: 1B8FH) occurs.

When Interpolation Method Specification (Interpolate) is "0: Linear interpolation", the operation profile data is as follows depending on the coordinate data.

Coordinate data	Description
Minimum value per cycle < Minimum value of input Maximum value of input < Maximum value per cycle	The control is performed with a line segment created from the coordinates of the nearest two points. (Example) When the resolution is "100" 
Minimum value of input < Minimum value per cycle Maximum value per cycle < Maximum value of input	Ignores the coordinate data of outside range of minimum value per cycle to maximum value per cycle. (Example) When the number of point data is "100" 

■Time per cycle

Set time that is required for one cycle.

Use when cam curve type is set to 5th Curve (Adj.).

■Stroke amount

Set the stroke amount.

When the output unit character string is "%", it will be a value corresponding to the 100% of stroke ratio.

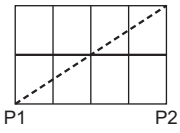
■I/O data

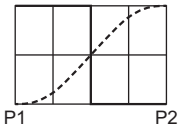
Set the I/O data.

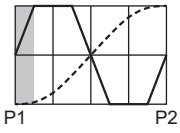
The input data should be set in ascending order.

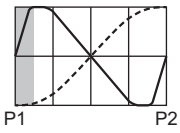
■End point

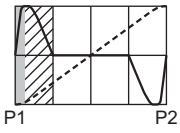
Set the end point of each section.

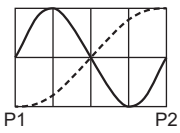


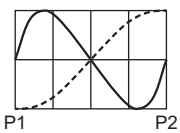


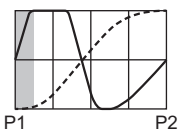


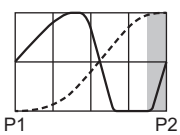




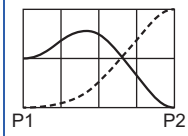


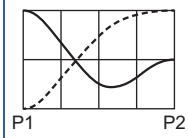


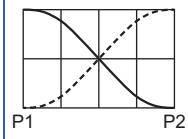


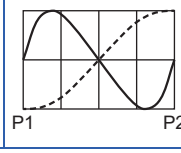


End point should be set in ascending order.









■Stroke

Set the stroke of each section.

■Cam curve types

A cam curve can be selected from the following curves.

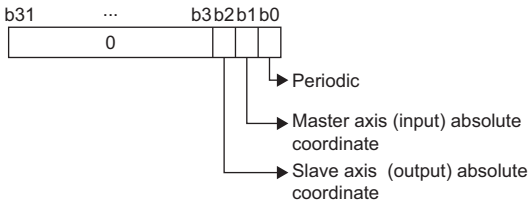
Cam curve type (MC_CAM_CURVE_TYPE)			Acceleration curve shape*1	Curve applicable range (P1 to P2)	Acceleration/ deceleration range compensation ( ): Default value		End point velocity	End point acceleration
Setting value	Cam curve name				Range L1	Range L2		
ConstantSpeed(0)	Constant velocity	Discontinuous		0.0 to 1.0	—	—	—	—
ConstantAcceleration(1)	Constant acceleration			0.0 to 1.0	—	—	—	—
DistortedTrapezoid(2)	Distorted trapezoid	Two-dwelling symmetrical		0.0 to 1.0	0.0001 ≤ L1 < 0.2500 (0.125)	—	—	—
DistortedSine(3)	Distorted sine			0.0 to 1.0	0.0001 ≤ L1 < 0.5000 (0.125)	—	—	—
DistortedConstantSpeedt (4)	Distorted constant velocity			0.0 to 1.0	0.0001 ≤ L1 < 0.1250 (0.0625)	0.0001 < L2 < 0.5000 (0.25)	—	—
Cycloid(5)	Cycloid			0.0 to 1.0	—	—	—	—
FifthCurve(6)	5th Curve			0.0 to 1.0	—	—	—	—
Trapecloid(7)	Trapecloid	Two-dwelling asymmetrical		0.0 to 1.0	0.0001 ≤ L1 < 0.2500 (0.125)	—	—	—
ReverseTrapecloid(8)	Reverse trapecloid			0.0 to 1.0	0.0001 ≤ L1 < 0.2500 (0.125)	—	—	—

Cam curve type (MC_CAM_CURVE_TYPE)			Acceleration curve shape*1	Curve applicable range (P1 to P2)	Acceleration/ deceleration range compensation ( ): Default value		End point velocity	End point acceleration
Setting value	Cam curve name				Range L1	Range L2		
DoubleHypotenuse(9)	Double hypotenuse	One-dwelling		0.0 to 1.0	—	—	—	—
ReverseDoubleHypotenuse(10)	Reverse double hypotenuse			0.0 to 1.0	—	—	—	—
Single Hypotenuse(11)	Single hypotenuse	Non-dwelling		0.0 to 1.0	—	—	—	—
FifthCurve_SpeedDesignation(12)	5th Curve (Adj.)	Two-dwelling symmetrical		0.0 to 1.0	—	—	-2500000000.0 to 2500000000.0	-2147483647.0 to 2147483647.0

*1 ---- : Stroke ratio, —— : Acceleration, ▭ : Range 1, ▨ : Range 2

■Read/write data structure

This section describes read data 1/write data 1 (Data1) and read data 2/write data 2 (Data2) specified by MCv_ReadProfileData (Profile Read)/MCv_WriteProfileData (Profile Write) when executing read/write operation profile data.



For details on each setting item, refer to the following.

☞ Page 827 Cam data

- Read data 1/Write data 1 (Data1)

  Specify the PROFILE_CAM_DATA type structure.

PROFILE_CAM_DATA			Device offset (Total size: 108 points)	Description
Variable name	Name	Data type		
Interpolate	Interpolation method specification	INT	+0	Set the interpolation method specification of the cam data. • 0: Linear interpolation • 1: Section interpolation • 2: Spline interpolation
Resolution	Resolution/number of coordinates	DWORD(UDINT)	+2	Set the resolution. Linear interpolation/specifying for each section/spline interpolation • 8 to 65535
InputUnitString	Input unit character string	WSTRING(31)	+4	Sets the unit for input data with a character string.
OutputUnitString	Output unit character string	WSTRING(31)	+36	Sets the unit for output data with a character string.
StartPoint	Start point*1	LREAL	+68	Set the start point. * Set "0.0".
StartStroke	Initial stroke amount*1	LREAL	+72	Set the stroke amount for the start point. (-Stroke amount (Stroke) ≤ Initial stroke amount (StartStroke) ≤ Stroke amount (Stroke))
StartVelocity	Initial velocity*2	LREAL	76	Set the velocity for the start point. (-2500000000.0 ≤ Initial velocity (StartVelocity) ≤ 2500000000.0)
StartAcceleration	Initial acceleration*2	LREAL	80	Set the acceleration for the start point. (-2147483647.0 ≤ Initial acceleration (StartAcceleration) ≤ 2147483647.0)

PROFILE_CAM_DATA			Device offset (Total size: 108 points)	Description
Variable name	Name	Data type		
CycleLength	Length per cycle*1	LREAL	+84	Set the input amount that is required for one cycle. (0.00000000000001 ≤ Length per cycle (CycleLength) ≤ 10000000000.0)
CycleMin	Minimum value per cycle	LREAL	+88	Set the minimum value per cycle. * Set "0.0".
CycleMax	Maximum value per cycle	LREAL	+92	Set the maximum value per cycle. (Minimum value per cycle (CycleMin) < Maximum value per cycle (CycleMax) ≤ 10000000000.0)
CycleTime	Time per cycle*2	LREAL	+96	Set time per cycle. (0.001 < Time per cycle (CycleTime) ≤ 100000.0)
Stroke	Stroke amount	LREAL	+100	Set the stroke amount. (0.00000000000001 ≤ Stroke amount (Stroke) ≤ 10000000000.0)
NumberOfSections	Number of sections*1	DWORD(UDINT)	+104	Sets the number of sections ■When set to "1: Section interpolation" • 1 to 360 ■When set to "2: Spline interpolation" • 3 to 360
Options	Options	DWORD(HEX)	+106	Specify options.  ■Periodic (bit 0) • 0: Non periodic • 1: Periodic For details, refer to the following. ☞ Page 804 Repetitive operation ■Master axis (input) absolute coordinate (bit 1) • 0: Relative coordinate For details, refer to the following. ☞ Page 809 Master axis absolute coordinate ■Slave axis (output) absolute coordinate (bit 2) • 0: Relative coordinate • 1: Absolute coordinate For details, refer to the following. ☞ Page 809 Slave axis absolute coordinate * For bits 3 to 31, specify "0".

*1 It is not used in the cam data format (Interpolation Method Specification (Interpolate) is "0: Linear Interpolation"). (It is ignored.)

*2 Used only when cam curve is 5th Curve (Adj.). (Ignore for other curve.)

Ex.

Setting example of Target (TARGET_REF.Target)

- [DEV](PROFILE_CAM_DATA)G11500000
- [VAR]CamData1 (CamData1 is a PROFILE_CAM_DATA type label.)
- Read data 2/Write data 2 (Data2)

  The structure to be specified differs depending on the setting of Read destination (Target)/Write destination (Target) and Interpolation Method Specification (Interpolate) of the target cam data. For details, refer to the following.

○: Supported, —: Not supported

FB	Read destination/ Write destination (Target)	Structure specified in Read data 2/Write data 2 (Data2)	Interpolation method specification (Interpolate)		
			0: Linear interpolation	1: Section interpolation	2: Spline interpolation
MCv_ReadProfileData (Profile Read)	0: Open area 2: Open area (Motion service processing)	LREAL[]	○	○*1	○*1
	1: File	LREAL[]	○	—	—
		PROFILE_CAM_ELEMENT[]	—	○	○*2
MCv_WriteProfileData (Profile Write)	0: Open area 2: Open area (Motion service processing)	LREAL[]	○	—	—
		PROFILE_CAM_ELEMENT[]	—	○	○*2
	1: File	LREAL[]	○	—	—
		PROFILE_CAM_ELEMENT[]	—	○	○*2

*1 Read as the stroke data (a pair data of current value per cycle and stroke) expanded to the open area.
X of the first point data is the value set in the start point and Y of the first point data is the value set in the initial stroke amount.
The data of the second point or later is the stroke data divided by resolution.
Therefore, the number of read/write points in an open area is "Resolution + 1".

*2 Used only by end point and stroke

If the number of elements of the specified array is smaller than the resolution + 1/number of coordinates when reading/writing the entire operation profile data, Number of read/write data mismatch (error code: 1BACH) occurs.
The structures specified by Read data 2/Write data 2 (Data2) are shown below.

- LREAL type
  Specify LREAL type two-dimensional array as follows.
  LREAL[m..n, o..p]

Item	Description
The number of elements (n - m + 1)	Set the number of array elements to be equal to or greater than the number of points that are to be read. When reading/writing the entire operation profile data (Offset and Points are "0"), set it to be the resolution + 1/number of coordinates of the target cam data or more. However, an area larger than the resolution + 1/number of coordinates read by Read data 1 (Data1) is not updated when using MCv_ReadProfileData (Profile Read). Data of an area larger than the resolution + 1/number of coordinates specified by Write data 1 (Data1) is not used when using MCv_WriteProfileData (Profile Write).
The number of dimensions (p - o + 1)	Read/write the current position per cycle and stroke of each point. Set the number of array elements to be "2". If the number of array elements is set to "3" or more, reading/writing is possible, but as the intended result may not be obtained due to data being moved forward, make sure to set the number of array elements to be "2".

Ex.
When setting LREAL type with Specifying interpolation method (Interpolate)

Interpolation method specification (Interpolate)	Setting example
0: Linear interpolation	The following shows examples of setting the two-dimensional device/label coordinate number "100" to Target (Target) of the TARGET_REF structure. ■Device specification TARGET_REF.Target := "[DEV](LREAL[1..100,1..2])D0" ■Label specification TARGET_REF.Target := "[VAR]CamData2" * CamData2 declares the "LREAL[1..100,1..2]" label to data type and label name of the global label to "CamData2", and specifies the string for Target (Target). Reading/writing data is as follows. · CamData2[n,1]: Nth point current position per cycle · CamData2[n,2]: Nth point stroke
1: Section interpolation 2: Spline interpolation	The following shows examples of setting the two-dimensional device/label resolution "100" to Target (Target) of the TARGET_REF structure. ■Device specification TARGET_REF.Target := "[DEV](LREAL[1..101,1..2])D0" ■Label specification TARGET_REF.Target := "[VAR]CamData2" * CamData2 declares the "LREAL[1..101,1..2]" label to data type and label name of the global label to "CamData2", and specifies the string for Target (Target). Reading/writing data is as follows. CamData2[1,1]: Value set for the start point · CamData2[1,2]: Value set for the initial stroke amount · CamData2[n + 1,1]: Nth point current position per cycle · CamData2[n + 1,2]: Nth point stroke

Point

When executing MCv_WriteProfileData (Profile Write) whose Target (Target) is File in the LREAL type array, Interpolation Method Specification (Interpolate) of the cam data format is output to the file as "0: Linear interpolation".

- PROFILE_CAM_ELEMENT type
  Specify PROFILE_CAM_ELEMENT type structure array as follows.
  PROFILE_CAM_ELEMENT[m..n]

Item	Description
The number of elements (n - m + 1)	Set the number of array elements to be equal to or greater than the number of points that are to be read. When reading/writing the entire operation profile data (Offset and Points are set to "0"), set it to be Number of Sections (PROFILE_CAM_DATA.NumberOfSections) of the target cam data or more. However, an area larger than Number of Sections (PROFILE_CAM_DATA.NumberOfSections) read by Read data 1 (Data1) is not updated when using MCv_ReadProfileData (Profile Read). An area larger than Number of Sections (PROFILE_CAM_DATA.NumberOfSections) specified by Write data 1 (Data1) is not used when using MCv_WriteProfileData (Profile Write).

Specify the following PROFILE_CAM_ELEMENT type structures.

PROFILE_CAM_ELEMENT			Device offset (Total size: 36 points)	Description
Variable name	Name	Data type		
CurveType	Cam curve type	MC_CAM_CURVE_TYPE	+0	Set the cam curve. (When End point (EndPoint) is 0, it is invalid.) • 0: Constant Velocity (ConstantSpeed) • 1: Constant Acceleration (ConstantAcceleration) • 2: Distorted Trapezoid (DistortedTrapezoid) • 3: Distorted Sine (DistortedSine) • 4: Distorted Constant Velocity (DistortedConstantSpeed) • 5: Cycloid (Cycloid) • 6: 5th Curve (FifthCurve) • 7: Trapecloid (Trapecloid) • 8: Reverse Trapecloid (ReverseTrapecloid) • 9: Double Hypotenuse (DoubleHypotenuse) • 10: Reverse Double Hypotenuse (ReverseDoubleHypotenuse) • 11: Single Hypotenuse (SingleHypotenuse) • 12: 5th Curve (Adj.) (FifthCurve_SpeedDesignation)
EndPoint	End point*1	LREAL	+4	Set the position to the length per cycle (the current value per cycle). (0.0 < End point (EndPoint) ≤ Length per cycle)
Stroke	Stroke	LREAL	+8	Set the stroke position. (The absolute value of Stroke (Stroke) ≤ Stroke amount)
RangeP1	Curve applicable range (P1)	LREAL	+12	Set the curve applicable range (start point: P1, end point: P2) for the cam curve. • 0.0 to 1.0 Set within the range of "P1 < P2". However, for "P1 = P2 = 0", "P1 = 0" and "P2 = 1" are applied.
RangeP2	Curve applicable range (P2)	LREAL	+16	
RangeL1	Acceleration/ deceleration range compensation (Range L1)	LREAL	+20	Set the acceleration/deceleration range (L1, L2) of the cam curve. (0.0001 < L1, L2 < 1.0000) The range that can be set differs depending on the cam curve. For "L1 = L2 = 0.0000", the default value for each cam curve is applied. On the curve that does not use L1 or L2, the setting value is ignored.
RangeL2	Acceleration/ deceleration range compensation (Range L2)	LREAL	+24	
EndVelocity	End point velocity*2	LREAL	+28	Set the end point velocity of the cam curve. (-2500000000.0 < End point velocity (EndVelocity) < 2500000000.0)
EndAcceleration	End point acceleration*2	LREAL	+32	Set the end point acceleration of the cam curve. (-2147483647.0 < End point acceleration (EndAcceleration) < 2147483647.0)

*1 When the end point exceeds the length per cycle before reaching the final section, the section number at the time is determined as the final section number and the end point is overwritten with the length per cycle.

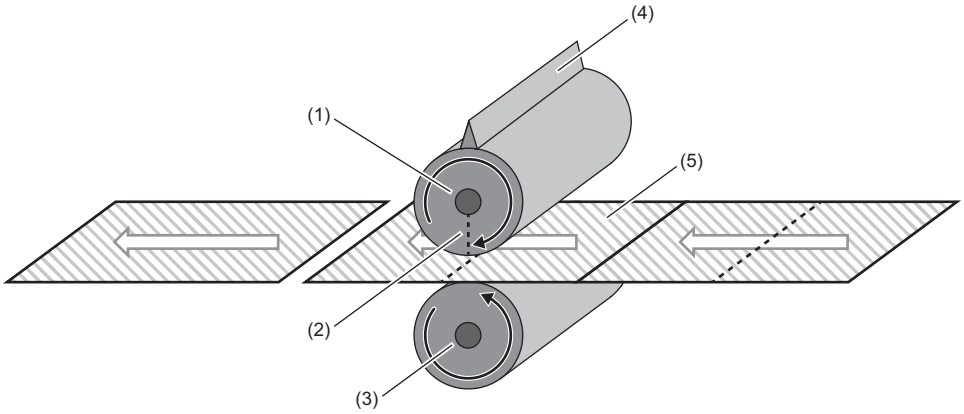
*2 Setting items used for read/write differ depending on Interpolation Method Specification (Interpolate) of the operation profile data. For details, refer to the following.

☞ Page 827 Cam data

Ex.

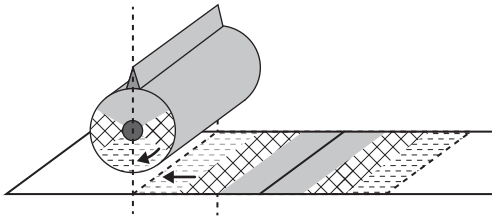
PROFILE_CAM_ELEMENT type

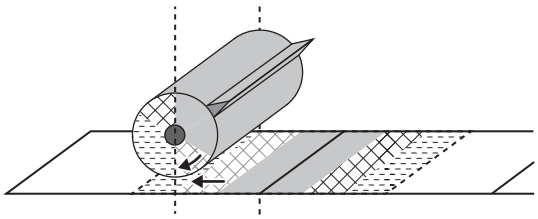
Interpolation method specification (Interpolate)	Setting example
0: Linear interpolation	The following shows examples of setting the device/label with the number of sections specified to "10" to Target (Target) of the TARGET_REF structure. ■Device specification TARGET_REF.Target := "[DEV](PROFILE_CAM_ELEMENT[1..10])D0" ■Label specification TARGET_REF.Target := "[VAR]CamData2" * CamData2 declares the "PROFILE_CAM_ELEMENT[1..10]" label to data type and label name of the global label to "CamData2", and specifies the string for Target (Target). Reading/writing data is as follows. · CamData2[n]: Nth point section data (PROFILE_CAM_ELEMENT type)

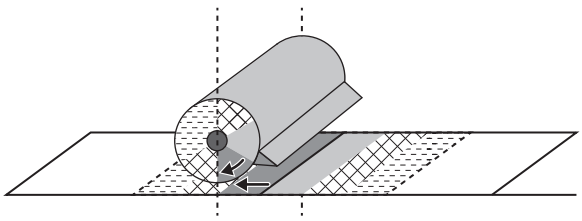


Rotary cutter

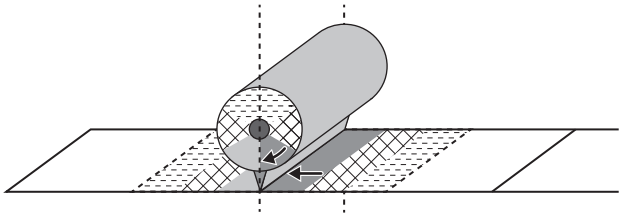
Generate cam data of the rotary cutter. The stroke data that is defined after equally dividing a cam pattern per cycle of rotary cutter by points of the resolution is opened in the open area.

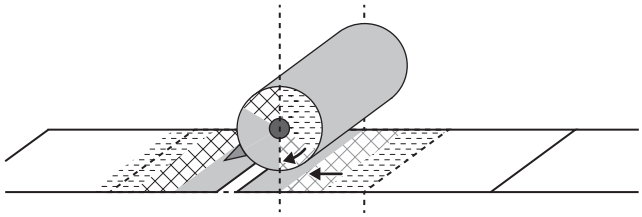


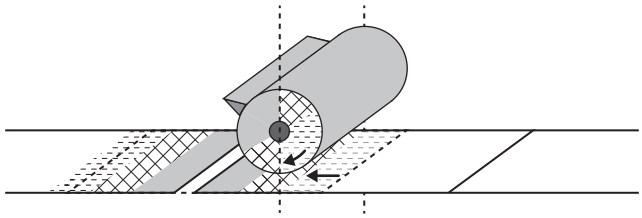


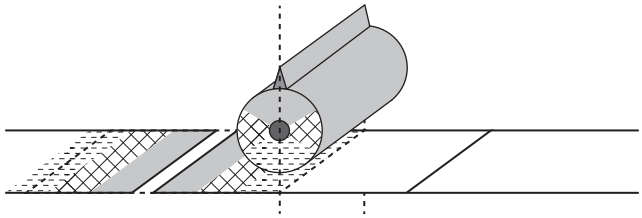


When using this operation profile data format, install add-on PackagingApp.









■Equipment image

An image of the rotary cutter equipment and its operation is shown below.

(1) Slave axis (synchronous axis)
(2) Cam data start position
(3) Master axis
(4) Cutter
(5) Sheet

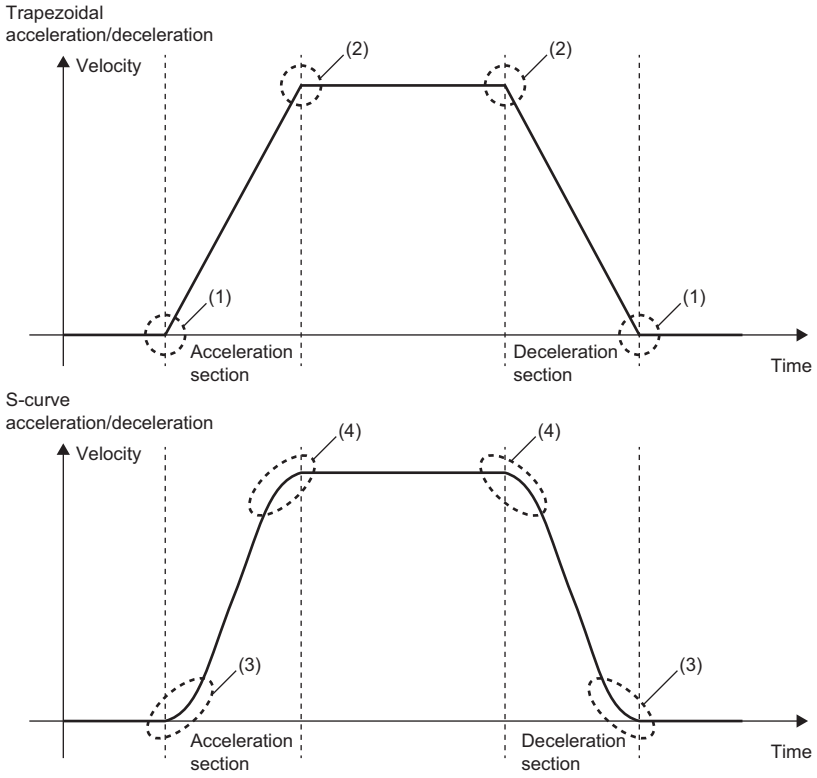
No.	Operation image	Description
1	Master axis (sheet) start position (= Cam data start position) Master axis (sheet) asynchronous constant speed section (first half) 	The master axis (sheet) and slave axis (synchronous axis) move at a constant speed that is different for each axis until they reach the start position of the master axis (sheet) acceleration/deceleration section. The speeds are automatically calculated from the setting values.
2	Master axis (sheet) acceleration/deceleration section (first half) 	The slave axis (synchronous axis) accelerates (or decelerates) until the end position of the master axis (sheet) acceleration/deceleration section is reached. The slave axis (synchronous axis) acceleration is determined by the acceleration/deceleration method and the ratio between the length of the master axis (sheet length) and that of the slave axis (synchronous axis length). • Master axis > Slave axis: Acceleration • Master axis = Slave axis: Constant speed (Their velocity is also the same.) • Master axis < Slave axis: Deceleration
3	From the master axis (sheet) synchronous section start position until the center position 	The master axis (sheet) and slave axis (synchronous axis) move at the same speed from the master axis (sheet) synchronous section start position until the synchronous section center position.

No.	Operation image	Description
4	From the master axis (sheet) synchronous section center position until the end position 	The slave axis (synchronous axis) cutter moves to the lowest position and cuts the sheet. Then, the master axis (sheet) and slave axis (synchronous axis) move at the same speed until they reach the synchronous section end position.
5	Master axis (sheet) acceleration/deceleration section (second half) 	The slave axis (synchronous axis) decelerates (or accelerates) until the end position of the master axis (sheet) acceleration/deceleration section is reached. The slave axis (synchronous axis) acceleration is determined by the acceleration/deceleration method and the ratio between the length of the master axis (sheet length) and that of the slave axis (synchronous axis length). • Master axis > Slave axis: Deceleration • Master axis = Slave axis: Constant speed (Their velocity is also the same.) • Master axis < Slave axis: Acceleration
6	Master axis (sheet) asynchronous constant speed section (second half) 	The master axis (sheet) and slave axis (synchronous axis) move at a constant speed that is different for each axis until they reach the master axis (sheet) end position. The speeds are automatically calculated from the setting values.
7	Master axis (sheet) end position (= Cam data end position) 	When the master axis (sheet) has moved the distance of the sheet length, the slave axis (synchronous axis) moves one revolution, completing the operation of one cycle. The operation returns to the start of the next cycle (No.1).

■Setting items

For a necessary definition as cam data for the rotary cutter, refer to the following.

◎: Necessary, ○: Optional, —: Unnecessary



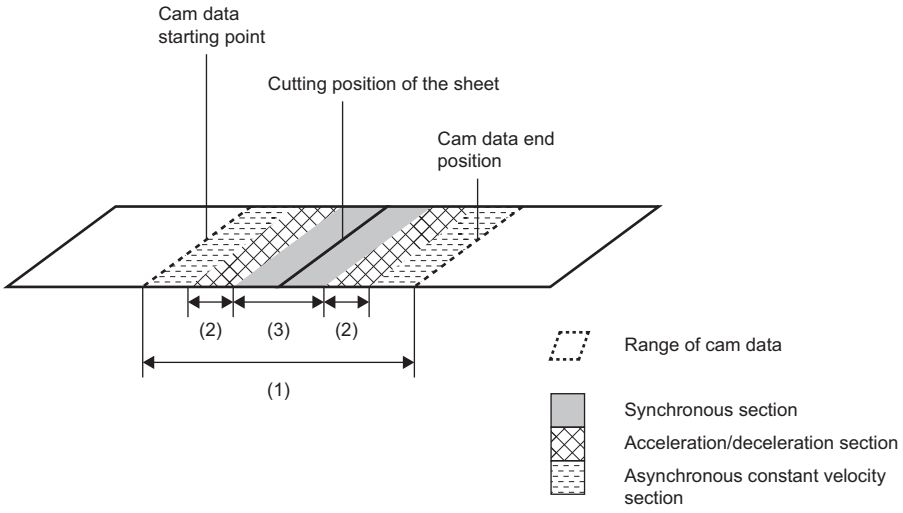
Setting item		Cam data for rotary cutter
Profile ID		○
Interpolation method specification		—
Resolution/number of coordinates		◎
Input unit character string		○
Output unit character string		—
Start point		—
Initial stroke amount		—
Initial velocity		—
Initial acceleration		—
Parameter	Auto-generation options	◎
	Synchronous section acceleration ratio	◎
	Sheet length	◎
	Sheet synchronization width	◎
	Synchronous axis length	◎
	Synchronous position adjustment	◎
	Acceleration/ deceleration width	◎
	Number of cutters	◎
Length per cycle		—
Minimum value per cycle		—
Maximum value per cycle		—
Time per cycle		—
Stroke amount		—(Fixed to 360)

■Auto-generation options

• Acceleration/deceleration method

Set the acceleration/deceleration method for the acceleration/deceleration section by using trapezoidal acceleration/deceleration or S-curve acceleration/deceleration.

The velocity changes by each method as shown below.



(1) Accelerates quickly.
(2) Decelerates quickly.
(3) Accelerates slowly.
(4) Decelerates slowly.

• Synchronous axis length setting

Set the setting method for the synchronous axis length by using the diameter or cycle length (circumference).

For differences in the setting methods, refer to the following.

☞ Page 841 Synchronous axis length

(1) Sheet length
(2) Acceleration/deceleration width
(3) Sheet synchronization width

■Sheet length

Set the sheet length.

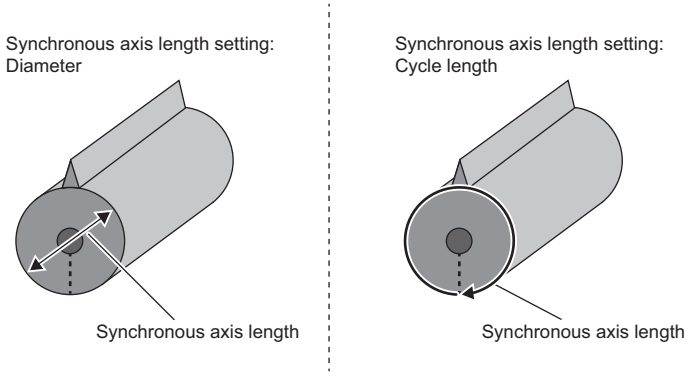
■Acceleration/deceleration width

Set the sheet width (one side) of the acceleration/deceleration section.

When the acceleration/deceleration width is set to a negative value, the acceleration/deceleration width is automatically calculated to be the maximum.

■Sheet synchronization width

Set the sheet synchronization width (seal width).



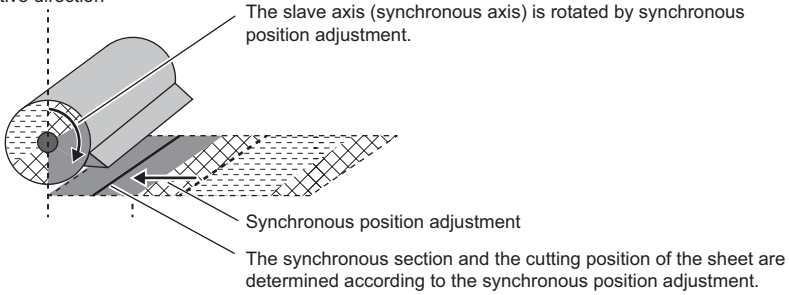
When the synchronous section for retracting operation is required in front of and behind the sheet synchronization width, add the retracting width.

■Synchronous axis length

Set the rotary cutter axis length.

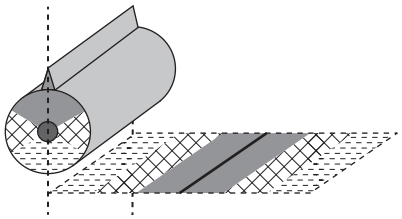
When the synchronous axis length is set by diameter, the cycle length equals the setting value × the circle ratio (π).

When the synchronous axis length is set by cycle length, the cycle length equals the setting value.



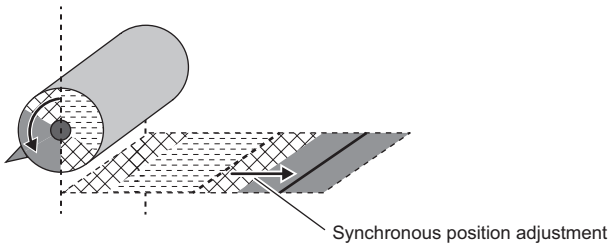
■Synchronous position adjustment

Set the position adjustment of the synchronous section. Set a value half the sheet length or shorter.



- Negative value: The synchronous section is adjusted to the sheet start side.
- 0: The synchronous section is at the sheet center position.
- Positive value: The synchronous section is adjusted to the sheet end side.

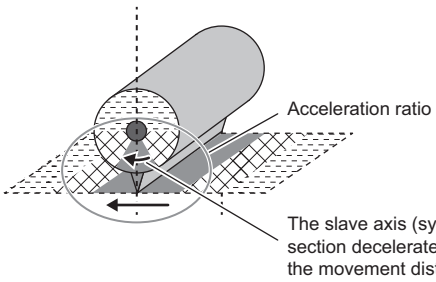
When the synchronous speed section for retracting operation is included in the synchronous section, adjust for the retracting width.



Synchronous position adjustment:
Negative direction

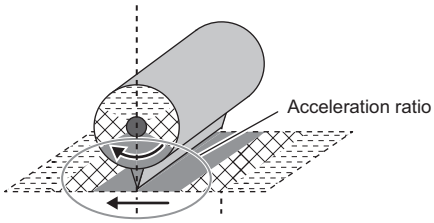
Synchronous position adjustment:
None

Synchronous position adjustment:
Positive direction



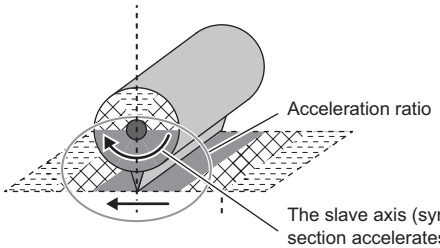
■Synchronous section acceleration ratio

Set when the synchronous speed in the synchronous section needs to be adjusted.



The speed is "Synchronous speed × (100% + Acceleration ratio)" in the synchronous section.

Acceleration ratio: -50.0%



The slave axis (synchronous axis) in the synchronous section decelerates. (Because the axis moves slowly, the movement distance becomes shorter.)

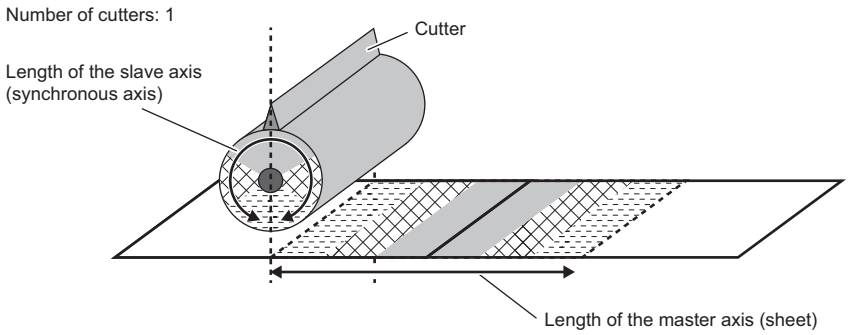
Acceleration ratio: 0.0%

Acceleration ratio: +50.0%

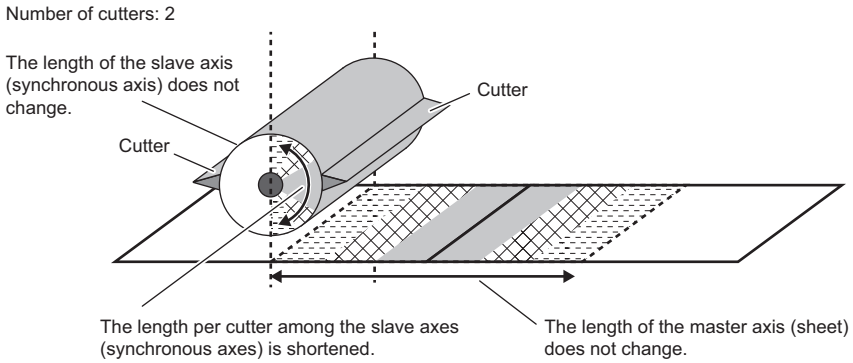
The slave axis (synchronous axis) in the synchronous section accelerates. (Because the axis moves fast, the movement distance becomes longer.)

■Number of cutters

Set the number of rotary cutters.

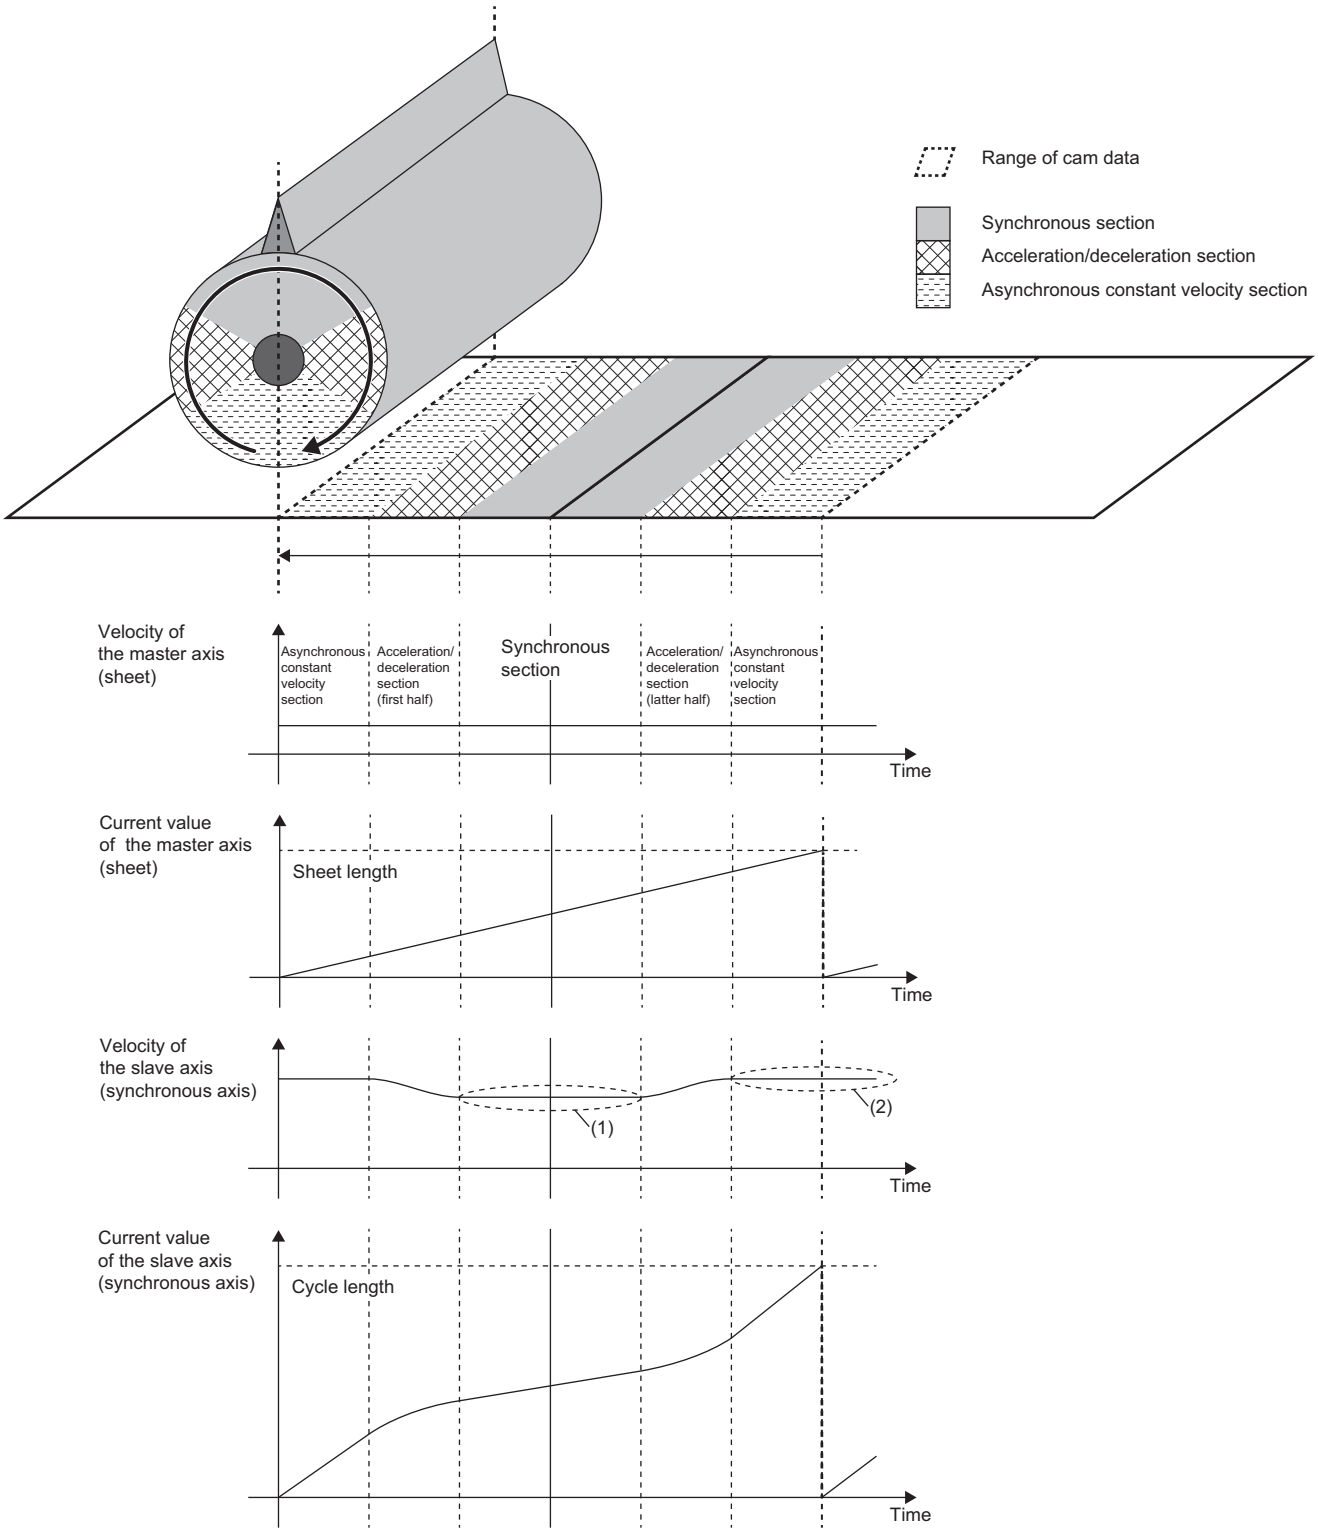


The length of each cutter will be shortened if the number of cutters is set to 2 or more. Adjust the stroke amount of the output axis.



• Cam operation (MC_CamIn)

Set the slave axis scaling (MC_CamIn.SlaveScaling) to 1 ÷ the number of cutters.



• Advanced synchronization (MCv_AdvancedSync)

Set the output axis cam stroke amount (ADV_OUTPUT.Pr.Cam.StrokeAmount) to the cycle length ÷ the number of cutters.

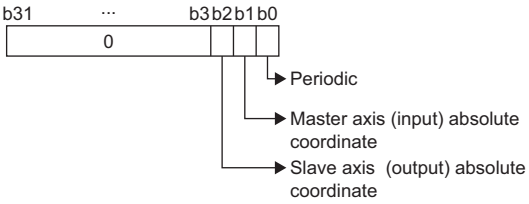
■Timing chart

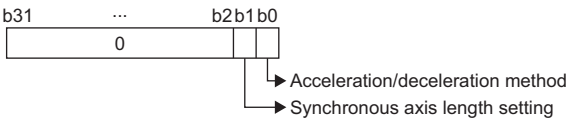
(1) The speed in the synchronous section is the same as that of the master axis.
(2) The speed in the asynchronous constant speed section is automatically calculated.

■Read/write data structure

This section describes Read data 1/Write data 1 (Data1) specified by MCv_ReadProfileData (Profile Read)/ MCv_WriteProfileData (Profile Write) when reading/writing operation profile data.

Read data 2/Write data 2 (Data2) is not used when reading/writing operation profile data of rotary cutter.





However, when reading the expanded cam data by using the cam data for rotary cutter from the open area again, set the cam data format (Interpolation Method Specification (Interpolate): "0: Linear interpolation"). For details on the data structure for read/write specified with cam data format, refer to the following.

☞ Page 832 Read/write data structure

■Rotary cutter (Specifying a double-precision real number)

• Read data 1/Write data 1 (Data1)

Specify the PROFILE_ROTARY_CUTTER type structure.

PROFILE_ROTARY_CUTTER			Device offset (Total size: 68 points)	Description
Variable name	Name	Data type		
Resolution	Resolution	DWORD(UDINT)	+0	Sets the resolution for generating the cam. • 8 to 32768
InputUnitString	Input unit character string	WSTRING(31)	+2	Sets the input unit character string.
Options	Options	DWORD(HEX)	+34	Specify options.  ■Periodic (bit 0) • 0: Non periodic • 1: Periodic For details, refer to the following. ☞ Page 804 Repetitive operation ■Master axis (input) absolute coordinate (bit 1) • 0: Relative coordinate For details, refer to the following. ☞ Page 809 Master axis absolute coordinate ■Slave axis (output) absolute coordinate (bit 2) • 0: Relative coordinate • 1: Absolute coordinate For details, refer to the following. ☞ Page 809 Slave axis absolute coordinate * For bits 3 to 31, specify "0".*1
AutoGenerationOptions	Auto-generation options	WORD(HEX)	+36	Sets the auto-generation options.  ■Acceleration/deceleration method (bit 0) • 0: Trapezoidal acceleration/deceleration • 1: S-curve acceleration/deceleration ■Synchronous axis length setting (bit 1) • 0: Diameter • 1: Cycle length * For bits 2 to 15, specify "0".
NumberOfCutter	Number of cutters	WORD(UINT)	+37	Set the number of cutters. • 1 to 256
SyncSectionAccRatio	Synchronous section acceleration ratio	LREAL	+40	Set when the synchronous speed in the synchronous section needs to be adjusted. The speed is "Synchronous speed × (100% + Acceleration ratio)" in the synchronous section. • -5000.0 to 5000.0 (in increments of 0.01%)
SheetLength	Sheet length	LREAL	+44	Set the sheet length. (0.0 < Sheet length (SheetLength) ≤ 10000000000.0)
SheetSyncWidth	Sheet synchronization width	LREAL	+48	Set the sheet synchronization width (seal width). When the synchronous speed section for retracting operation is required in front of and behind the sheet synchronization width, add the retracting width. (0.0 < Sheet synchronization width (SheetSyncWidth) < Sheet length (SheetLength)) (0.0 < Sheet synchronization width (SheetSyncWidth) < Cycle length / Number of cutters (NumberOfCutter))

PROFILE_ROTARY_CUTTER			Device offset (Total size: 68 points)	Description
Variable name	Name	Data type		
SyncAxisLength	Synchronous axis length	LREAL	+52	• Set the rotary cutter axis length. ■When Auto-generation options is set to "0: Diameter" It is calculated as "Cycle length = Setting value × π". ■When Auto-generation options is set to "1: Cycle length" It is calculated as "Cycle length = Setting value". (0.0 < Cycle length < 10000000000.0)
SyncPositionAdjustment	Synchronous position adjustment	LREAL	+56	Set the position adjustment of the synchronous section. • Negative value: The synchronous section is adjusted to the sheet start side. • 0: The center of the sheet is in the synchronous section. • Positive value: The synchronous section is adjusted to the sheet end side. (The absolute value of Synchronous position tuning (SyncPositionAdjustment) < Sheet length (SheetLength) / 2)
AccDecWidth	Acceleration/ deceleration width	LREAL	+60	Set the sheet width (one side) of the acceleration/deceleration area. When a negative value is set, the acceleration/deceleration width is calculated to be the maximum. (2 × Acceleration/deceleration width (AccDecWidth) ≤ Sheet length (SheetLength) - Sheet synchronization width (SheetSyncWidth))
AsyncSpd	Asynchronous velocity result	LREAL	+64	When the auto-generation is successfully completed, the asynchronous speed is stored as the ratio of the synchronous speed.

*1 If specifying other than "0", Out of option range (error code: 1BC3H) occurs, and the function will not start.

• Read data 2/Write data 2 (Data2)

Specifying is not required. (It is ignored.)

Multiple axes positioning data

For a necessary definition as positioning data, refer to the following table.

◎: Necessary, ○: Optional, —: Unnecessary

Setting item		Multiple axes positioning data
Profile ID		○
Periodic		—
Input absolute coordinate		—
Output absolute coordinate		—
Operation profile data format		◎
Profile data type		◎
Interpolation method specification		—

*1 Whether the setting is required differs depending on the control method (ControlMethod). For details, refer to the following.
☞ Page 668 Positioning data to be set

■Profile ID

An unique ID to be assigned by expanding.

ID can be specified with any number.

■Operation profile data format

Set "multiple axes positioning data format" when using the operation profile data format.

■Profile data type

Set "multiple axes positioning data" when using the profile data type.

■Number of positioning data settings

Specify the number of positioning data to be set.

Set the number of positioning data settings so that it is equal to or less than the total count of positioning data.

During write processing, the motion system will automatically calculate the number of positioning data settings. Therefore, the settings are not required.

If the value is out of the setting range or the total number of positioning data, Operation profile data incorrect (error code: 1B8FH) will occur during expanding.

- Setting range: 0 to 5000

■Total number of positioning data

The total number of positioning data.

Specify the maximum value of positioning data No. to be set for expanding or writing.

If the value is out of the setting range, Operation profile data incorrect (error code: 1B8FH) will occur during expanding.

- Setting range: 1 to 5000

Point

The larger the total number of positioning data, the more positioning data can be set, but the data size increases accordingly. For details on the data size, refer to the following.

☞ Page 865 Capacity of operation profile data

■Condition signal 1 to Condition signal 10 (ConditionSignal1 to ConditionSignal10)

Set execution conditions for JUMP when "0082H: JUMP (JUMP)" is set to the control method (ControlMethod). The following initial values are used if the settings of each item are omitted.

For details on each item and setting range, refer to the following.

☞ Page 691 Condition signal setting

Item	Initial value
I/O number (StartIO)	0
Target (Target)	"" (string of length 0)
Signal detection method (Detection)	0: Detection at TRUE (HighLevel)
Compensation time (CompensationTime)	0.0
Filter time (FilterTime)	0.0

■Skip signal (SkipSignal1 to SkipSignal10)

Set the skip signal to be used for operation profile data control.

For details on each item and setting range, refer to the following.

☞ Page 692 Skip signal setting

Item	Initial value
I/O number (StartIO)	0
Target (Target)	"" (string of length 0)
Signal detection method (Detection)	0: Detection at TRUE (HighLevel)
Compensation time (CompensationTime)	0.0
Filter time (FilterTime)	0.0

■Positioning data

Set the interpolation operation to perform in operation profile data control. The following initial values are used if the settings of each item are omitted.

For details on each item and setting range, refer to the following.

☞ Page 668 Positioning data to be set

Item	Initial value
Positioning data No. (DataNo)	Omission impossible
Operation pattern (OperationPattern)	0: Positioning complete (PositioningComplete)
Control method (ControlMethod)	Omission impossible
Interpolation axis 1 to Interpolation axis 4 (InterpolationAxis1 to InterpolationAxis4)	0
Circular interpolation mode (CircMode)	0: Border point specification (mcBorder)
Path selection (CircPathChoice)	0: CW (mcCW)
Target position/Movement amount/End point 1 to Target position/Movement amount/End point 4 (Position1 to Position4)	0.0
Direction selection 1 to Direction selection 2 (Direction1 to Direction4)	0
Sub point 1 to Sub point 4 (CircAuxPoint1 to CircAuxPoint4)	0.0
Velocity mode (VelocityMode)	0: Vector Velocity (VectorSpeed)
Velocity (Velocity)	0.0
Acceleration (Acceleration)	0.0
Deceleration (Deceleration)	0.0
Jerk (Jerk)	0.0
Circular interpolation error tolerance (CircErrorTolerance)	100.0
Positioning data options (DataOptions)	00000000H
Dwell time (DwellTime)	0.0
M code (Mcode)	0
M code output timing override (McodeOutput_Override)	0: Use FB options (UseFbOptions)
Jump destination positioning data No. (JumpDestinationDataNo)	0
Condition signal No. (ConditionSignalNo)	0
Number of LOOP to LEND repetitions (LoopCount)	0
Skip signal No. (SkipSignalNo)	0
Pitch (Pitch)	0

■Read/write data structure

This section describes Read data 1/Write data 1 (Data1) and Read data 2/Write data 2 (Data2) specified by MCv_ReadProfileData (Profile Read)/MCv_WriteProfileData (Profile Write) when reading/writing operation profile data.

- Read data 1/Write data 1 (Data1)

  Specify the PROFILE_POSITIONING_DATA type structure for Read data 1/Write data 1 (Data1).

PROFILE_POSITIONING_DATA			Device offset (Total size: 4 points)	Description
Variable name	Name	Data type		
NumberOfDataSettings	Number of positioning data settings	WORD (UINT)	+0	Set the number of positioning data to be set.*1 • 0 to 5000
TotalNumberOfData	Total number of positioning data	WORD (UINT)	+1	Set the total number of positioning data.*2 • 1 to 5000
Options	Options	DWORD(HEX)	+2	Set options. * Set "00000000H".

*1 During MCv_WriteProfileData (Profile Write) processing, the motion system will automatically calculate the number of positioning data settings (NumberOfDataSettings). Therefore, the settings are not required.

*2 When the expanded/written profile ID is specified and overwritten by MCv_WriteProfileData (Profile Write), if the total number of positioning data (TotalNumberOfData) does not match, the original expanded data is discarded.
When the number of write data (Points) is set to a value other than "0" and is partially overwritten by MCv_WriteProfileData (Profile Write), set the total number of positioning data (TotalNumberOfData) to match.

Ex.

When setting a device or label

Specification method	Setting example
Device	Data1.Target := "[DEV](PROFILE_POSITIONING_DATA)D0";
Label*1	Data1.Target := "[VAR]G_stPositioningData";

*1 The following labels are declared on the global label.

Label name	Data type
G_stPositioningData	PROFILE_POSITIONING_DATA

- Read data 2/Write data 2 (Data2)

  Specify the following structures for Read data 2/Write data 2 (Data2).

Structure	Description
PROFILE_POSITIONING_DATA_ELEMENT	• Specify when reading/writing positioning data. • The condition signal and skip signal are not read or written. *1
PROFILE_POSITIONING_DATA_EXTENDED	• Specify when reading/writing condition signal, skip signal, and positioning data. • The condition signal or skip signal can be specified to omit the reading/writing.*1 • The condition signal and skip signal can be read/written, but the processing time increases accordingly.

*1 When the expanded/written profile ID is specified and is overwritten by MCv_WriteProfileData (Profile Write), if the total number of positioning data is the same as the original expanded data, the data not to be written is held. (If the total number of positioning data is different, the data not to be written is discarded.)

■PROFILE_POSITIONING_DATA_ELEMENT type

- Specify the PROFILE_POSITIONING_DATA_ELEMENT (m..n) type structure.
- Set the number of specified array elements (n - m + 1) to be equal to or greater than the number of points that are to be read/written. When reading/writing entire operation profile data (Offset and Points are set to "0"), set the number of array elements to be the total number of positioning data (PROFILE_POSITIONING_DATA.TotalNumberOfData) or more. If the number of array elements is few, Number of read/write data mismatch (error code: 1BACH) will occur.

PROFILE_POSITIONING_DATA_ELEMENT [m..n]			Device offset (Total size: 88 points)	Description
Variable name	Name	Data type		
DataNo	Positioning data No.	WORD (UINT)	+0	Set the index number of positioning data. • 1 to total number of positioning data
OperationPattern	Operation pattern	MC_OPERATION_PATTERN	+1	Set the operation pattern.*1 • 0: Positioning complete (PositioningComplete) • 1: Continuous positioning (ContinuousPositioning) • 2: Continuous path (BlendingLow) (ContinuousBlendingLow) • 3: Continuous path (BlendingPrevious) (ContinuousBlendingPrevious) • 4: Continuous path (BlendingNext) (ContinuousBlendingNext) • 5: Continuous path (BlendingHigh) (ContinuousBlendingHigh)
ControlMethod	Control method	MC_CONTROL_METHOD	+2	Set the control method.*1 • 0080H: NOP (NOP) • 0082H: JUMP (JUMP) • 0083H: LOOP (LOOP) • 0084H: LEND (LEND) • 0101H: Absolute value linear interpolation (LinearAbsolute) • 0102H: Relative value linear interpolation (LinearRelative) • 0103H: Absolute value circular interpolation (CircularAbsolute) • 0104H: Relative value circular interpolation (CircularRelative)
InterpolationAxis1	Interpolation axis 1	WORD (UINT)	+3	Set the linear interpolation axes of linear interpolation and the circular interpolation axes of circular interpolation by the setting of control method (ControlMethod).*1 ☞ Page 679 Interpolation axis 1 to Interpolation axis 4 (InterpolationAxis1 to InterpolationAxis4)
InterpolationAxis2	Interpolation axis 2	WORD (UINT)	+4	
InterpolationAxis3	Interpolation axis 3	WORD (UINT)	+5	
InterpolationAxis4	Interpolation axis 4	WORD (UINT)	+6	
CircMode	Circular interpolation mode	MC_CIRC_MODE	+7	Set the specification method of circular interpolation.*1 • 0: Border point specification (mcBorder) • 1: Center point specification (mcCenter) • 2: Radius specification (mcRadius)
CircPathChoice	Path selection	MC_CIRC_PATHCHOICE	+8	Set the rotation direction of circular interpolation.*1 • 0: CW (mcCW) • 1: CCW (mcCCW) • 2: Shortcut (mcShortWay) • 3: Detour (mcLongWay) • 4: CW Detour (mcCWLongWay) • 5: CCW Detour (mcCCWLongWay)
Reserve1 [0..2]	Reserve 1	WORD (UINT)	+9	Not used. (For offset adjustment)
Position1	Target position/ Movement amount/ End point 1	LREAL	+12	Set the target position, movement amount, and end point by the setting of control method (ControlMethod).*1 ☞ Page 680 Target position/Movement amount/End point 1 to Target position/Movement amount/End point 4 (Position1 to Position4)
Position2	Target position/ Movement amount/ End point 2	LREAL	+16	
Position3	Target position/ Movement amount/ End point 3	LREAL	+20	
Position4	Target position/ Movement amount/ End point 4	LREAL	+24	
Direction1	Direction selection 1	MC_DIRECTION	+28	For the linear interpolation control, set the direction of movement from the current position to the target position.*1 • 1: Positive direction (mcPositiveDirection) • 2: Negative direction (mcNegativeDirection) • 3: Shortest path (mcShortestWay)
Direction2	Direction selection 2	MC_DIRECTION	+29	
Direction3	Direction selection 3	MC_DIRECTION	+30	
Direction4	Direction selection 4	MC_DIRECTION	+31	

PROFILE_POSITIONING_DATA_ELEMENT [m..n]			Device offset (Total size: 88 points)	Description
Variable name	Name	Data type		
CircAuxPoint1	Sub point 1	LREAL	+32	For the circular interpolation control, set the position from the current position at startup to the boundary point and the center point.*1 ■For "0: Border point specification (mcBorder)", "1: Center point specification (mcCenter)" -10000000000.0 to 10000000000.0 ■For "2: Radius specification (mcRadius)" 0.000001 to 2147483647.0
CircAuxPoint2	Sub point 2	LREAL	+36	
CircAuxPoint3	Sub point 3	LREAL	+40	
CircAuxPoint4	Sub point 4	LREAL	+44	
VelocityMode	Velocity mode	MC_INTERPOLATE_SPEED_MODE	+48	Set the velocity mode of linear interpolation control.*1 • 0: Vector Velocity (VectorSpeed) • 1: Long Axis Velocity (LongAxisSpeed) • 2: Reference Axis Velocity (ReferenceAxisSpeed)
Reserve2 [0..2]	Reserve 2	WORD (UINT)	+49	Not used. (For offset adjustment)
Velocity	Velocity	LREAL	+52	Set the positioning speed for multiple axes interpolation.*1 • 0.0, 0.0001 to 2500000000.0
Acceleration	Acceleration	LREAL	+56	Set the acceleration for multiple axes interpolation.*1 • 0.0000, 0.0001 to 2147483647.0
Deceleration	Deceleration	LREAL	+60	Set the deceleration for multiple axes interpolation.*1 • 0.0000, 0.0001 to 2147483647.0
Jerk	Jerk	LREAL	+64	Set the jerk for multiple axes positioning control.*1 • 0.0000, 0.0001 to 2147483647.0
CircErrorTolerance	Circular interpolation error tolerance	LREAL	+68	Set the allowable rang of circular interpolation error.*1 • 0.000001 to 100000.0
DataOptions	Positioning data options	DWORD (HEX)	+72	Set the options of linear interpolation or circular interpolation.*1 ☞ Page 683 Positioning data options (DataOptions)
Reserve3 [0..1]	Reserve 3	WORD (UINT)	+74	Not used. (For offset adjustment)
DwellTime	Dwell time	LREAL	76	Set the dwell time.*1 • 0.0 [s]: Dwell function disabled • 0.000001 [s] to 8400.0 [s]: Dwell function enabled
Mcode	M code	WORD (UINT)	+80	Set M code.*1 • 0 to 65535 * Set "0" when not using M code.
McodeOutput_Override	M code output timing override	MC_MCODE_OUTPUT_OVERRIDE	+81	Set M code output timing.*1 • 0: Use FB options (UseFbOptions) • 1: WITH mode (WithMode) • 2: AFTER mode (AfterMode)
JumpDestinationDataNo	Jump destination positioning data No.	WORD (UINT)	+82	Set the jump destination positioning data No.*1 • 1 to total number of positioning data (5000)
ConditionSignalNo	Condition signal No.	WORD (UINT)	+83	Set the condition signal No.*1 • 0 to 10 * Set "0" when not using the condition signal.
LoopCount	Number of LOOP to LEND repetitions	WORD (UINT)	+84	Set the number of repetitions of loop control.*1 • 1 to 65535
SkipSignalNo	Skip signal No.	WORD (UINT)	+85	Set the skip signal No.*1 • 0 to 10 * Set "0" when not using the skip signal.
Pitch	Pitch	WORD (UINT)	+86	Not used. * Set "0" when writing data.
Reserve4	Reserve 4	WORD (UINT)	+87	Not used. (For offset adjustment)

*1 When writing data, no error occurs due to the setting value. When the written open area is used by the operation profile data control FB, an error occurs if it is outside the setting range.

Ex.

When setting the device/label with the number of elements "10" in "Data2.Target"

Specification method	Setting example
Device	Data2.Target := "[DEV](PROFILE_POSITIONING_DATA_ELEMENT[1..10])D100";
Label*1	Data2.Target := "[VAR]G_st10PositioningDataElem";

*1 The following labels are declared on the global label.

Label name	Data type
G_st10PositioningDataElem	PROFILE_POSITIONING_DATA_ELEMENT [1..10]*2

*2 Reading/writing data is as follows.
G_st10PositioningDataElem [n]: The nth positioning data (PROFILE_POSITIONING_DATA_ELEMENT type)

■PROFILE_POSITIONING_DATA_EXTENDED type

- Specify the PROFILE_POSITIONING_DATA_EXTENDED type structure. Specify variables for each member (WSTRING type) to store the condition signal, skip signal, and positioning data. The condition signal (ConditionSignal), skip signal (SkipSignal), and positioning data (PositioningData) of the specification destination are the target of reading/writing.
- The target of the reading/writing section specified by offset (Offset) and number of read/write data (Points) is positioning data (PositioningData).

PROFILE_POSITIONING_DATA_EXTENDED			Device offset (Total size: 192 points)	Description
Variable name	Name	Data type		
ConditionSignal*1	Condition signal	WSTRING (63)	+0	Set the condition signal by TARGET_REF type string. For details, refer to the following. ☞ Page 1158 TARGET_REF Structure The following shows the setting range of string.*2 ■Data type • [VAR] • [DEV] ■Type • PROFILE_SIGNAL_SELECT_ELEMENT * When "" (no setting) is set, reading/writing is not performed.
SkipSignal*1	Skip signal	WSTRING (63)	+64	Sets skip signal by TARGET_REF type string. For details, refer to the following. ☞ Page 1158 TARGET_REF Structure The following shows the setting range of string.*2 ■Data type • [VAR] • [DEV] ■Type • PROFILE_SIGNAL_SELECT_ELEMENT * When "" (no setting) is set, reading/writing is not performed.
PositioningData	Positioning data	WSTRING (63)	+128	Set positioning data by TARGET_REF type string. For details, refer to the following. ☞ Page 1158 TARGET_REF Structure The following shows the setting range of the string. ■Data type • [VAR] • [DEV] ■Type • PROFILE_POSITIONING_DATA_ELEMENT * When "" (no setting) is set, Read/Write data type incorrect (error code: 1BAAH) will occur.

*1 Specify PROFILE_SIGNAL_SELECT_ELEMENT [o..p] type structure for the PROFILE_POSITIONING_DATA_EXTENDED type member condition signal (ConditionSignal) and skip signal (SkipSignal).
From the element of the start number "o", reading/writing is performed for Condition signal 1 to Condition signal 10 (ConditionSignal1 to ConditionSignal10) or Skip signal 1 to Skip signal 10 (SkipSignal1 to SkipSignal10) accordingly.

*2 When the specified type does not satisfy the request of each structure member, Read/Write data type incorrect (error code: 1BAAH) will occur. When the specified data type does not satisfy the request of each structure member, Read/Write data data type incorrect (error code: 1BA8H) will occur.

■PROFILE_SIGNAL_SELECT_ELEMENT [o..p] type

PROFILE_SIGNAL_SELECT_ELEMENT [o..p]*1			Device offset (Total size: 76 points)	Description*2
Variable name	Name	Data type		
StartIO	I/O number	WORD (HEX)	+0	Not used. Ignores the setting.
Reserve1	Reserve 1	WORD (UINT)	+1	Not used. (For offset adjustment)
Target	Target	WSTRING (63)	+2	Set the signal to be used by the string. For details, refer to the following. ☞ Page 1158 TARGET_REF Structure The following shows the setting range of the string. • ""*3 ■Data type • [OBJ]*4 • [VAR] • [DEV] ■Type • BOOL
Detection	Signal detection method	MC_SIGNAL_LOGIC	+66	Specify the logic of signal. • 0: Detection at TRUE (HighLevel) • 1: Detection at FALSE (LowLevel)
Reserve2	Reserve 2	WORD (UINT)	+67	Not used. (For offset adjustment)
CompensationTime	Compensation time	LREAL	+68	Set "0.0".
FilterTime	Filter time	LREAL	+72	Set the filter time for removing chattering of the I/O signals in units of seconds. • 0.0 to 5.0 [s]

*1 If the number of elements (p - o + 1) is less than 10, reading/writing is performed only for the number of elements.
If the number of elements for the specified variable is more than 10, the 11th and subsequent elements are not used.

*2 When writing data, no error occurs due to the setting value. When the written open area is used by the operation profile data control FB, an error occurs if it is outside the setting range.

*3 If the target (Target) is "" (string that has a length of 0), the corresponding skip signal is considered as not set.

*4 If [OBJ] is set, the target modification cannot be omitted. If the setting is complete with the target modification omitted, Operation profile data control specification profile incorrect (error code: 1B2CH) will occur.

Ex.

When setting the device/label of the condition signal (ConditionSignal), skip signal (SkipSignal), and positioning data (PositioningData) (20 points) in "Data2.Target"

Specification method	Setting example
Device*1	G_stPositioningDataExt.ConditionSignal := "[DEV](PROFILE_SIGNAL_SELECT_ELEMENT[1..10])D1000"; G_stPositioningDataExt.SkipSignal := "[DEV](PROFILE_SIGNAL_SELECT_ELEMENT[1..10])D2000"; G_stPositioningDataExt.PositioningData := "[DEV](PROFILE_POSITIONING_DATA_ELEMENT[1..20])D3000"; Data2.Target := "[VAR]G_stPositioningDataExt";
Label*1	G_stPositioningDataExt.ConditionSignal := "[VAR]G_st10ConditionSignal"; G_stPositioningDataExt.SkipSignal := "[VAR]G_st10SkipSignal"; G_stPositioningDataExt.PositioningData := "[VAR]G_st20PositioningDataElem"; Data2.Target := "[VAR]G_stPositioningDataExt";

*1 The following labels are declared on the global label.

Label name	Data type
G_stPositioningDataExt	PROFILE_POSITIONING_DATA_EXTENDED
G_st10SkipSignal	PROFILE_SIGNAL_SELECT_ELEMENT [1..10]*2
G_st10ConditionSignal	PROFILE_SIGNAL_SELECT_ELEMENT [1..10]*2
G_st20PositioningDataElem	PROFILE_POSITIONING_DATA_ELEMENT [1..20]*2

*2 Reading/writing data is as follows.
· G_st10ConditionSignal [n]: The nth condition signal (PROFILE_SIGNAL_SELECT_ELEMENT type)
· G_st10SkipSignal [n]: The nth skip signal (PROFILE_SIGNAL_SELECT_ELEMENT type)
· G_st20PositioningDataElem [n]: The nth positioning data (PROFILE_POSITIONING_DATA_ELEMENT type)

Digital cam switch data

■Setting item

The following table lists definitions required for digital cam switch data.

◎: Necessary, ○: Optional, —: Unnecessary

Item		Necessary item
Profile ID		◎
Periodic		◎*1
Input absolute coordinate		◎*1
Output absolute coordinate		◎*1
Operation profile data format		◎
Profile data type		—
Interpolation method specification		—
Resolution/number of coordinates		—
Start point		—
Initial stroke amount		—
Initial velocity		—
Initial acceleration		—
Options		◎
Number of switches		◎
Reference velocity		○
Switch settings	FirstOnPosition	◎
	LastOnPosition	○
	Direction	◎
	CamSwitchMode	◎
	Duration	—
Length per cycle		—
Unit setting		○
Unit character string		○
Ring counter lower limit value		○
Ring counter upper limit value		○
Time per cycle		—
Stroke amount		—
Unit setting		—
Unit character string		—

*1 Set "1".

■Number of switches

Set the total number of switches. The number of switches can be set from 1 to 10000. Switch settings (FirstOnPosition, LastOnPosition, Direction, CamSwitchMode, Duration) can be defined for the number of switches.

■Switch settings

Set conditions to turn on the switches.

For details on the relationship between digital cam switch actions and each switch setting, refer to the following.

☞ Page 1179 Switch settings

• FirstOnPosition

When CamSwitchMode is set to 0: Switch disabled, this setting is ignored.

When CamSwitchMode is set to 1: Position-based, set the lower limit position of a section where the switches are to be turned on.

• LastOnPosition

When CamSwitchMode is set to 0: Switch disabled, this setting is ignored.

When CamSwitchMode is set to 1: Position-based, set the upper limit position of a section where the switches are to be turned on.

Point

In the motion system, the relationship between FirstOnPosition and LastOnPosition is not checked.

For actions when FirstOnPosition is greater than LastOnPosition, refer to the following.

☞ Page 1179 Switch settings

• Direction

Set the conditions to turn on the switches according to the input change direction.

Setting value	Direction specification	Operation pattern
0	Both directions	Turns on the switches regardless of the input change direction.
1	Positive direction	Turns on the switches only when the input change direction is in the positive direction.
2	Negative direction	Turns on the switches only when the input change direction is in the negative direction.

• CamSwitchMode

Set the method for specifying the conditions to turn on the switches.

Setting value	Specification method	Description
0	Switch disabled	Disables the switch.
1	Position-based	Specify the lower limit position at which the switches are to be turned on in FirstOnPosition. Specify the upper limit position at which the switches are to be turned on in LastOnPosition.

■Read/write data structure

Specify the following structures for Read data 1/Write data 1 (Data1) and Read data 2/Write data 2 (Data2) of MCv_ReadProfileData (Profile Read)/MCv_WriteProfileData (Profile Write).

Specify the sections to be controlled by using Offset (Offset) and Number of read/write data (Points).

• Read data 1/Write data 1 (Data1): Specify the PROFILE_CAMSWITCH_DATA type structure.

PROFILE_CAMSWITCH_DATA	Data type	Device offset (Total size: 80 points)	Description
InputUnitString	WSTRING (31)	+0	Sets the unit for input data with a character string.
NumberOfSwitches	DWORD (UDINT)	+32	Specify the number of switches. 1 to 10000
Options	DWORD (HEX)	+34	Specify options. ■Periodic (bit 0)*1 • 0: Non periodic • 1: Periodic For details, refer to the following. ☞ Page 804 Repetitive operation ■Input absolute coordinate (bit 1)*1 • 0: Relative coordinate • 1: Absolute coordinate For details, refer to the following. ☞ Page 809 Master axis absolute coordinate ■Output absolute coordinate (bit 2)*1 • 0: Relative coordinate • 1: Absolute coordinate For details, refer to the following. ☞ Page 809 Slave axis absolute coordinate * For bits 3 to 31, specify "0".
ReferenceSpeed	LREAL	+36	This setting is not used. Leave the default. (Default: 0.0)
ReferenceSpeedUnitString	WSTRING (31)	+40	This setting is not used. Leave the default. (Default: Empty)
RingCount_LowerValue	LREAL	+72	Set the ring counter lower limit value.
RingCount_UpperValue	LREAL	76	Set the ring counter upper limit value.

*1 Specify "1".

• Read data 2/Write data 2 (Data2): Specify the PROFILE_CAMSWITCH_ELEMENT type structure array.

PROFILE_CAMSWITCH_ELEMENT[m..n]*1	Data type	Device offset (Total size: 16 points)	Description
FirstOnPosition	LREAL	+0	Set the lower limit position at which the switches are to be turned on or the start position at which the switches are to be turned on. -10000000000.0 ≤ FirstOnPosition ≤ 10000000000.0
LastOnPosition	LREAL	+4	Set the upper limit position at which the switches are to be turned on. -10000000000.0 ≤ LastOnPosition ≤ 10000000000.0
Direction	INT	+8	Set the input direction in which the switches are to be turned on. • 0: Both directions • 1: Positive direction • 2: Negative direction
CamSwitchMode	INT	+9	Set how to specify the ON conditions. • 0: Switch disabled • 1: Position-based
Reserve	DINT	+10	Not used because this item is used for offset adjustment.
Duration	LREAL	+12	This setting is not used. The setting value is ignored.

*1 m and n will be any positive numbers that satisfy the following formula.
1 (Minimum number of switches) ≤ (n - m + 1)
When reading/writing the entire operation profile data (Offset and Points are set to 0), set it to be Number of switches (PROFILE_CAMSWITCH_DATA.NumberOfSwitches) of the target digital cam switch data or more.
However, an area larger than the number of switches read by Data1 is not updated when using MCv_ReadProfileData (Profile Read).
An area larger than the number of switches specified by Data1 is not used when using MCv_WriteProfileData (Profile Write).

Creating operation profile data

This section describes storage format and creating method of the operation profile data.

Storage format

The following storage format can be used as the operation profile data in the motion system.

Storage format	Description	Characteristics
Standard text format	Stores the operation profile data as a standard text file (csv file).	The data created in the engineering tool can be stored in this format.

Creating method when not using the engineering tool

When using the operation profile data in the control without using the engineering tool, execute the following procedures.

■When creating the operation profile data by a program

1. Store data (read/write data structure for each type) corresponding to the operation profile data format that will be created on the variables (labels and devices).
2. Set the profile data type (standard/function specific) label as needed. (When storing created operation profile data in the file, set the storage location in Operation profile data storage location (Location).)
3. When executing the operation profile data write FB, the control ID can be obtained in the profile ID type (standard/function specific) label.
4. Execute the control FB by using the profile ID type (standard/function specific) label.

■When using the operation profile data created outside

1. Store the operation profile data in an arbitrary place such as a user drive and an SD memory card.
2. Set the storage location in Operation profile data storage location (Location) of the profile data type (standard/function specific) label.
3. When executing the open FB, the control ID can be obtained in the profile ID type (standard/function specific) label.
4. Execute the control FB by using the profile ID type (standard/function specific) label.

Creating method when using the engineering tool

When the operation profile data is created in the engineering tool, the profile data type global label whose label name is the operation profile data name is automatically added, and it can be used in the program. The set description (storage location and ID) is reflected as the label initial value.
When a profile ID type whose profile data type is "function-specific" is included as a member, the setting details are reflected to the profile ID type of "function-specific" as the initial value.

Ex.
When the operation profile data of "name: ProfileData0001", "format: cam data", and "profileID: 1" is created, ProfileData0001.CamID.ProfileID initial value is "1". (Same as the initial value of ProfileData0001.ProfileData.ID.Number.)
The profile ID type of "function specific type" can be used as input/output parameters or an input parameter of the operation profile data control FB.

Point

- Profile data type labels created by the engineering tool cannot be edited on the global label editor. Be sure to create and edit it on the operation profile data create window.
- The default write destination for operation profile data created by the engineering tool is "/rom/$MELPRJ$/calc_profile_" or "/sdc/$MELPRJ$/calc_profile_". Files within this folder (including the sub folders) may be overwritten or deleted by the engineering tool operation. Therefore, store the operation profile data file created by the program in a location other than the folder above (including the sub folders).

■File batch online change and writing to the programmable controller

When operation profile data is added by file batch online change or writing to the programmable controller, it is not automatically expanded after completion. The added operation profile data is expanded at power-on.
Do not execute a file batch online change or writing to the programmable controller while the program is accessing the storage area. It may corrupt the file.

Operating operation profile data

Operation profile data uses files and open areas, and performs operation profile data manipulation and operation profile data controls.

Operation profile data related function		Description
Operation profile data manipulation	Operation profile data open	Performs open of operation profile data from "File" to "Open area".
	Operation profile data read/write	Performs read/write of operation profile data of "File" and "Open area". Uses read/write data structure.
	Operation profile data deletion	Deletes the operation profile data of "File".
Operation profile data control		Performs control by using operation profile data of "Open area".

Data type of operation profile data

The profile data type and the profile ID type can be used as the data type to perform operation profile data manipulation/ operation profile data controls.

- "File" is managed by the profile data type labels.
  Specify the file path and file name in Operation profile data storage location (PROFILE_DATA.Location).
- "Open area" is managed by the profile ID type labels.
  When writing operation profile data in the open area by the operation profile data manipulation (open/write), the ID is assigned in the open area by specifying arbitrary ID for Profile ID No. (PROFILE_ID.Number).
- Control can be carried out by specifying the label of profile ID type at the operation profile data controls.

Entity of operation profile data	Description	Data type for operation/control	Remarks
File	Written by the following operation. • Write from the engineering tool • Operation profile data write FB execution (The write destination is "File")	Profile data type • General type (PROFILE_DATA type) • Function specific type (MC_CAM_REF type or others)	Data is preserved even when the power turns off.
Open area	Written by the following operation. • Operation profile data expand execution (Auto expand/operation profile data expand FB execution) • Operation profile data write FB execution (The write destination is "Open area")	Profile ID type • General type (PROFILE_ID type) • Function specific type (MC_CAM_ID type or others)	Data actually used in the control is stored. The data is deleted when the power turns off.

Point

Even if the data in open area is changed by MCv_WriteProfileData (Profile Write) (open area specification) during operation, the change is deleted when the power turns off. To hold the change, write to the file by MCv_WriteProfileData (Profile Write) (file specification).

■Details of profile data type/profile ID type

The profile data type structure and the profile ID type structure include "general-purpose type" which does not limit functions and "function specific type" which is used for the specific functions (FB). "Function specific type" includes "general-purpose type" in the member. Furthermore, the profile data type of "function specific type" includes the profile ID type of "function specific type" as a member. Create instances of variable corresponding to the FB argument type to use.

Type name	General-purpose type	Function specific type	Description
Profile data type	PROFILE_DATA	• MC_CAM_REF • MC_POSITIONING_DATA_REF • MC_CAMSWITCH_REF	Indicates the operation profile data with the following configurations. • Operation profile data storage location (FILE_Location) • Profile ID (PROFILE_ID) • I/O number • Profile ID type of function specific type (MC_CAM_ID or others)
Profile ID type	PROFILE_ID	• MC_CAM_ID • MC_POSITIONING_DATA_ID • MC_CAMSWITCH_DATA_REF	Data type to specify the operation profile data to use in the operation profile data control FB (MC_CamIn (Cam Operation Start) or others) A unique identifiable No. is given by the operation profile data expand FB (MC_CamTableSelect (Cam Table Selection) or others) • Profile ID No. (Number) • I/O number • Flag in use

The following table shows data type and open FBs that can be used for each function.

Function (Operation profile data control)	Profile data type	Profile ID type	Open FB
Cam operation (MC_CamIn (Cam Operation Start))	MC_CAM_REF	MC_CAM_ID	MC_CamTableSelect (Cam Table Selection)
Multiple axes positioning data operation (MCv_MovePositioningData (Multiple Axes Positioning Data Operation))	MC_POSITIONING_DATA_REF	MC_POSITIONING_DATA_ID	—
Digital cam switch output (MC_DigitalCamSwitch (Digital Cam Switch Output))	MC_CAMSWITCH_REF	MC_CAMSWITCH_DATA_REF	—
Advanced synchronous control (MCv_AdvancedSync (Advanced Synchronous Control))	MC_CAM_REF	MC_CAM_ID	MC_CamTableSelect (Cam Table Selection)
Advanced synchronous control current position per cycle calculation (MCv_AdvPositionPerCycleCalc (Advanced Synchronous Control Current Position Per Cycle Calculation))	MC_CAM_REF	MC_CAM_ID	MC_CamTableSelect (Cam Table Selection)
Advanced synchronous control cam set position calculation (MCv_AdvCamSetPositionCalc (Advanced Synchronous Control Cam Set Position Calculation))	MC_CAM_REF	MC_CAM_ID	MC_CamTableSelect (Cam Table Selection)

■Operation profile data operation in the engineering tool

When operating from the engineering tool, the set operation profile data file reads, writes to, and verifies files. Operation profile data file cannot read, write to, or verify the open area.

■Capacity of operation profile data

Data size that created operation profile data file uses is as shown below.

Operation method	Operation profile data format	Open area
Create with the engineering tool/ Create with operation profile data manipulation function	Cam data	■When Interpolation Method Specification (Interpolate) is "0: Linear Interpolation": Management information (1K bytes) + Number of coordinates × 8 × 2 bytes ■When Interpolation Method Specification (Interpolate) is "1: Section interpolation" or "2: Spline interpolation": Management information (1K bytes) + Resolution × 8 bytes
	Rotary cutter	Management information (1K bytes) + Resolution × 8 bytes
	Digital cam switch data	Management information (1K bytes) + Total number of switches × 32 bytes
	Multiple axes positioning data	Management information (1K bytes) + 3200 bytes + Total number of positioning data × 176 bytes

In operation profile data open processing, the memory used is as follows: temporarily twice the data size of open area when cam data (Interpolation Method Specification (Interpolate) is "1: Section interpolation" or "2: Spline interpolation") and rotary cutter are used; and the same data size as that of open area for other cases.

Operation profile data expansion

This section describes auto expand and expand.

Expand the operation profile data created by "File" to "Open area" because operation profile data of "Open area" is used for operation profile data control.

The method to expand to "Open area" has the following two types.

- Auto expand
- Operation profile data expand FB execution

■Auto expand of operation profile data

Operation profile data, which is created using the engineering tool and set for auto expand, is expanded automatically when the controller is powered on. Therefore, it can be used for operation profile data control without executing an operation profile data expand FB.

The operation profile data satisfying all the following conditions can be used for its control without executing the operation profile data expand FB because it is also expanded automatically when the controller is powered on.

- Other than "0" is specified to the initial value of Profile ID No. (PROFILE_DATA.ID.Number).
- The operation profile data is stored in "%CALC_PROFILE_ROOT_DRIVE%/calc_profile_/".
- No error such as out of the setting range in the data to be expanded.

The operation profile data for automatic expansion is searched from both "%CALC_PROFILE_ROOT%/calc_profile_/" and "%CALC_PROFILE_ROOT_DRIVE%/calc_profile_/".

When operation profile data with the same ID is stored in both paths above, the operation profile data stored in "%CALC_PROFILE_ROOT_DRIVE%/calc_profile_/" has priority.

When automatically expanding operation profile data from a location other than the data memory (drive 4), change the operation profile data root drive (MotionSystem.PrConst.ProfileRootDrive).

Ex.

When automatically expanding operation profile data on the SD memory card, set the operation profile data root drive (MotionSystem.PrConst.ProfileRootDrive) to /sdc.

If the specified drive is not available, such as when an SD memory card is not inserted, no error occurs and no operation is performed.

The motion function section will not enter into RUN state until all operation profile data is automatically expanded. If there are many operation profile data, it may take time for the motion function section to enter into RUN state.

Point

- When auto expand is set, regarding Profile ID No. (PROFILE_DATA.ID.Number), Periodic (Periodic), Master axis absolute coordinate (MasterAbsolute), and Slave axis absolute coordinate (SlaveAbsolute) which can be specified in the operation profile data expand FB, the same parameters in the csv file are expanded.
- When there is operation profile data which does not meet the requirement above during auto expand, Details of the error are registered in the event history without automatically expanding the profile data. In this case, the operation continues until automatically expanding the remaining operation profile data, without ending because of error.

■Operation profile data expansion

Expands "File" specified in Operation Profile Data Storage Location (PROFILE_DATA.Location) to "Open area" by using MC_CamTableSelect (Cam Table Selection).

- Expanded data to "Open area" is assigned profile IDs expressed in the profile ID type.
- The operation profile data expand FB that can be used differs depending on the defined profile data type. For details, refer to the following.

  ☞ Page 826 Operation profile data types

  If an operation profile data expand FB that does not support the profile data type is executed, Operation profile data incorrect (error code: 1B8FH) occurs.
- When an error has occurred while expanding the operation profile data, "Open area" in processing is discarded.

When Operation profile data storage location (PROFILE_DATA.Location) is a relative path and the operation profile data is expanded from a location other than the data memory (drive 4), change the operation profile data root drive (MotionSystem.PrConst.ProfileRootDrive).

Ex.

When automatically expanding operation profile data on the SD memory card, set the operation profile data root drive (MotionSystem.PrConst.ProfileRootDrive) to /sdc.

Precautions

When rewriting "Open area" during control, the stroke value changes rapidly, and shock may be applied to the machine depending on the waveform pattern. Create operation profile data so that the waveform before and after change does not become discontinuous.

Point

- Expansion process of the operation profile data is performed with motion service processing. It may take time to open depending on the processing details and the operation profile data.
- When Profile ID No. (PROFILE_DATA.ID.Number), Periodic (Periodic), Master axis absolute coordinate (MasterAbsolute), and Slave axis absolute coordinate (SlaveAbsolute) are present as input arguments for the operation profile data expand FB, the value set in "File" is ignored and the expansion is performed while referencing the input argument settings. (The setting value of "File" is not overwritten.)

Read/write operation profile data

Performs read/write of operation profile data.

Performs read/write of file and operation profile data in open area by using MCv_ReadProfileData (Profile Read)/ MCv_WriteProfileData (Profile Write) according to data structure for read/write.

Read/write is available for operation profile data format to which the data structure for read/write is defined. For details on the data structure for read/write of each operation profile data format, refer to the following.

☞ Page 826 Operation profile data types

If an error occurs while operation profile data is being written, the open area and the file in processing are discarded.

Point

The number of data points that can be read/written at the same time is limited. If read/write is not completed in one time FB execution, perform it in several times.

■Read operation profile data

Operation profile data can be read by using the MCv_ReadProfileData (Profile Read).

- The file specified in Profile data (ProfileData) and Read destination (Target), or the operation profile data in open area are read for the number of points specified in Number of read data (Points) from data specified with Offset (Offset).
- To read the entire operation profile data, specify "0" in both Offset (Offset) and Number of read data (Points).
- Read data is stored in variables specified in Read data 1 (Data1) and Read data 2 (Data2).

■Write operation profile data

Performs write of operation profile data.

Operation profile data can be written by using the MCv_WriteProfileData (Profile Write).

- The file specified in Profile data (ProfileData) and Write destination (Target), or the operation profile data in open area are written for the number of points specified in Number of write data (Points) from data specified with Offset (Offset).
- To write the entire operation profile data, specify "0" in both Offset (Offset) and Number of write data (Points).
- Write data is specified with variables specified in Write data 1 (Data1) and Write data 2 (Data2).

Operation profile data deletion

Operation profile data can be deleted by file batch online change or writing to the programmable controller. When operation profile data has been deleted, the file is deleted during file batch online change or when writing to the programmable controller.

Control of operation profile data

Operation profile data is used for control of each function.

Control details

The input data of operation profile data control FB is the PROFILE_ID type and the control is executed based on the specified operation profile data. Before executing operation profile data control, open the operation profile data corresponding to each operation profile data control FB in the open area to enable this control.

For the operation profile data control FB corresponding to each operation profile data, refer to the following.

Operation profile data format	Operation profile data control FB	Details
Cam data Rotary cutter	• MC_CamIn (Cam Operation Start) • MCv_AdvancedSync (Advanced Synchronous Control) • MCv_AdvPositionPerCycleCalc (Advanced Synchronous Control Current Position Per Cycle Calculation) • MCv_AdvCamSetPositionCalc (Advanced Synchronous Control Cam Set Position Calculation)	For details, refer to the following. ☞ Page 784 Cam Operation ☞ Page 889 ADVANCED SYNCHRONOUS CONTROL
Digital cam switch data	MC_DigitalCamSwitch (Digital Cam Switch Output)	For details, refer to the following. ☞ Page 1175 DIGITAL CAM SWITCH
Multiple axes positioning data	MCv_MovePositioningData (Multiple Axes Positioning Data Operation)	For details, refer to the following. ☞ Page 665 Multiple Axes Positioning Data Operation

Start mode

The following shows the operation when simultaneously executing various FBs (open, write, read, control) that access open areas of operation profile data to the same profile ID.

Execution mode (ExecutionMode)

For the operation profile data expand FB and the operation profile data write FB, the operation for simultaneous execution can be specified with Execution mode (ExecutionMode).

○: Execution possible, ×: Error

On-going FB	FB to be executed			
	Open/Write			Read/Control
	0: Execute Immediately (mcImmediately)	1: Execute at Completion of Previous One (mcQueued)	3: Execute Speculatively (mcSpeculatively)	
Open/Write	○	○	×	×
Read/Control	○	○	×	○

■0: Execute Immediately (mcImmediately)

The description in the open area is immediately changed by an open FB and a write FB. The change may affect the control in execution.

However, if the state falls under one of the following cases when executing open/write during FB execution, Operation profile data being operated (error code: 1B90H) occurs.

- The operation profile data format to open/write and the open area operation profile data format do not match.
- The operation profile data capacity to open/write and the open area capacity*1 do not match.

*1 For the open area capacity, refer to the following.
☞ Page 865 Capacity of operation profile data

■1: Execute at Completion of Previous One (mcQueued)

Waits execution completion of on-going FB. When multiple FBs are waiting, the FBs will be executed in high priority task. For the same priority, the FBs will be executed in the order of the start.

The status of execution completion of each FB is shown below.

FB	Status
MC_CamTableSelect (Cam Table Selection)	Execution completion (Done) = TRUE
MCv_ReadProfileData (Profile Read)	Execution completion (Done) = TRUE
MCv_WriteProfileData (Profile Write)	Execution completion (Done) = TRUE
MC_CamIn (Cam Operation Start)	Periodic (MC_CamTableSelect.Periodic) = TRUE: Abortion of execution (MC_CamIn.CommandAborted) = TRUE Periodic (MC_CamTableSelect.Periodic) = FALSE: Abortion of execution (MC_CamIn.CommandAborted) = TRUE, Cam cycle completion (MC_CamIn.EndOfProfile) = TRUE
MCv_AdvancedSync (Advanced Synchronous Control)	Executing (Busy) = FALSE
MCv_AdvPositionPerCycleCalc (Advanced Synchronous Control Current Position Per Cycle Calculation)	Executing (Busy) = FALSE
MCv_AdvCamSetPositionCalc (Advanced Synchronous Control Cam Set Position Calculation)	Executing (Busy) = FALSE
MC_DigitalCamSwitch (Digital Cam Switch Output)	Executing (Busy) = FALSE
MCv_MovePositioningData (Multiple Axes Positioning Data Operation)	Busy = FALSE, and MCv_MovePositioningData (Multiple Axes Positioning Data Operation) running profile number (CurrentProfileNo) = 0

■3: Execute Speculatively (mcSpeculatively)

Operation profile data being operated (error code: 1B90H) occurs and the open area is not changed.

Point

When no FB is in execution, the FB is executed immediately regardless of specification of Execution mode (ExecutionMode).

While the FBs (open, write, read, control) that access open areas are in execution, Executing (Busy) of each FB is TRUE. Use this signal for the interlock as needed.

Sub function of operation profile data

Current value change per cycle function

Change the current value per cycle of an operation profile data control FB to an arbitrary value.

- Sets Instance ID (MC_CamIn.InstanceID) of the target operation profile data control FB (hereinafter called to as MC_CamIn) to Instance ID (InstanceID) of MCv_ChangeCycle (Current Value Change per Cycle).
- Public variables of MC_CamIn are shown below when current value change per cycle is performed.

Public variable	Updating value	Remarks
Current value per cycle (InputPerCycle)	Value specified in Current value per cycle (Cycle[])	—
Reference value (Reference)	Stroke value equivalent to Current value per cycle (Cycle[])	Reference value (MC_CamIn.Reference) is refreshed to fix Output value (MC_CamIn.OutputData).
Output value (OutputData)	Not updated	—

Point

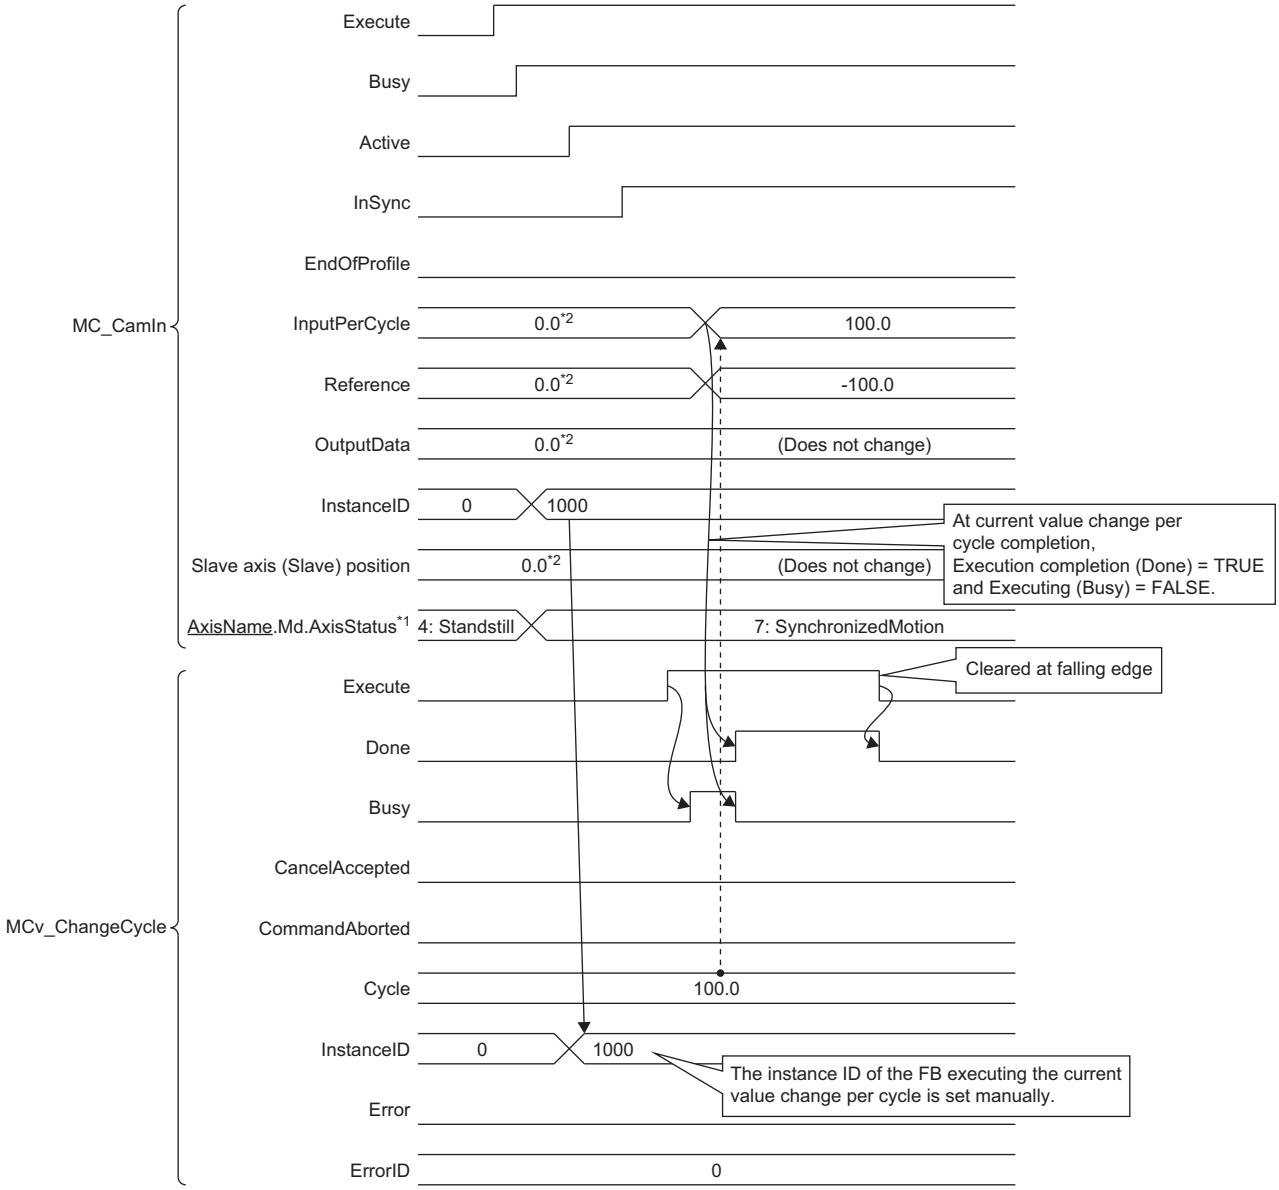
Even if Slave axis absolute coordinate (MC_CamTableSelect.SlaveAbsolute) is TRUE (absolute coordinate), Reference value (Reference) is refreshed to fix Output value (OutputData) if current value change per cycle is performed.

- The method for current value change per cycle is as follows.

Method	Description
MCv_ChangeCycle (Current Value Change per Cycle)	Change it to the specified value at control execution.

- For specification of the current value per cycle to be changed, "absolute specification" or "relative specification" can be selected by Relative position selection (Relative).
- If Current value change per cycle is performed for an operation profile data control FB other than MC_CamIn, Current value change per cycle unsupported (error code: 1BAFH) occurs.

■Current value change per cycle

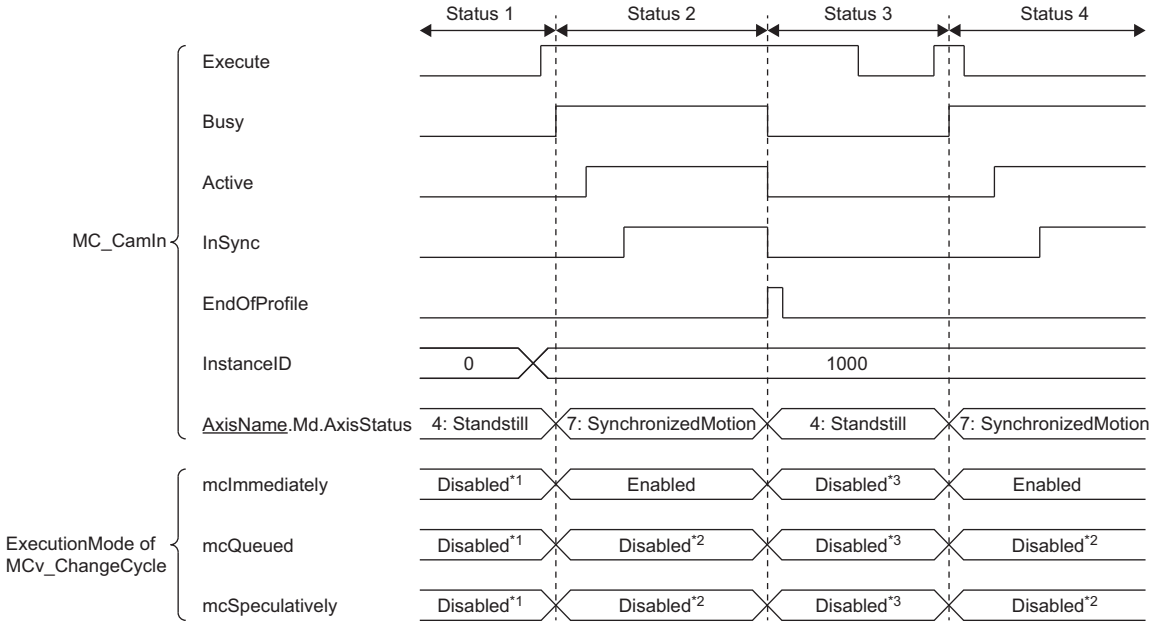


Uses MCv_ChangeCycle (Current Value Change per Cycle).

Changes the current value per cycle of the specified operation profile data control FB.

Executes current value change per cycle at rising edge detection of Execute command (Execute).

Ex.



Sets Current value per cycle (Cycle) = 100.0 when Executing (MC_CamIn.Busy) = TRUE, and when executing current value change per cycle. (Current value of Master axis (Master) of MC_CamIn (Cam Operation Start) shall not change.)

*1 This is the state of Slave axis (Slave).

*2 Does not change because the master axis does not move.

Current value change per cycle timing by each value

*1 MCv_ChangeCycle instruction error (error code: 1BB9H) (Detail Code: 000AH) occurs.

*2 MCv_ChangeCycle instruction error (error code: 1BB9H) (Detail Code: 0002H) occurs.

Operation details for each status are shown below.

Status of FB of current value change per cycle target		Condition of state transition (Status change of the slave axis)		Operation of current value change per cycle
		Before transition	After transition	
Status 1	FB is not started	—(Initial state)	4: Standby (Standstill)	MCv_ChangeCycle instruction error (error code: 1BB9H) (Detail Code: 000AH) occurs regardless of Execution mode (ExecutionMode).
Status 2	FB is starting	4: Standby (Standstill)	7: During synchronous operation (SynchronizedMotion)	Depending on Execution mode (ExecutionMode), the timing is as follows ■0: Execute Immediately (mcImmediately) Current value change per cycle can be executed. The current value is reflected at the execution cycle of the change target FB. ■1: Execute at Completion of Previous One (mcQueued) MCv_ChangeCycle instruction error (error code: 1BB9H) (Detail Code: 0002H) occurs. ■3: Execute Speculatively (mcSpeculatively) MCv_ChangeCycle instruction error (error code: 1BB9H) (Detail Code: 0002H) occurs.
Status 3	After completion of FB control	7: During synchronous operation (SynchronizedMotion)	4: Standby (Standstill)	Current value change per cycle cannot be executed regardless of Execution mode (ExecutionMode). MCv_ChangeCycle instruction error (error code: 1BB9H) (Detail Code: 000AH) occurs.
Status 4	After restart of FB	4: Standby (Standstill)	7: During synchronous operation (SynchronizedMotion)	The operation is the same as Status 2. Then, the cycle of Status 4 (Status 2) → Status 3 →, ··· will be repeated. Current value change per cycle operation is not affected even Execute command (Execute) has TRUE/FALSE differences in Status 2 and Status 4.

Precautions

Relevant add-ons

The following add-ons are required to use this function.

- ProfileControl
- PackagingApp (when using the rotary cutter)

System memory capacity

■RAM usage

Refer to the following.

☞ Page 865 Capacity of operation profile data

■Backup RAM usage

Backup RAM is not used.

32.2 Operation Profile Data Format

This section describes csv file format of operation profile data.

Point

- "//" comment lines are not counted among line Nos.
- 8 byte specification data is imported as the double-precision real number type.

Operation profile data details

The basic configuration of profile data is shown below.

Line No.	Description
1	Common header
2	Open information
3	Operation profile data format
4	Resolution/number of coordinates
5	Start point, initial stroke amount, options
6	Number of sections
7 or later	Defined for each operation profile data format
N-2*1	Length per cycle
N-1*1	Stroke amount
N*1	Common footer (EOF)
N+1*1	Common footer (CRC)

*1 "N" is calculated as shown below by Interpolation Method Specification (Interpolate) in the operation profile data format.

Operation profile data format	Interpolation method specification (Interpolate)	N
Cam data format	0: Linear interpolation	7 (start row of previous step) + (number of coordinates × 2) + 2 (length of 1 cycle, stroke amount)
	1: Section interpolation	7 (start row of previous step) + Number of sections + 2 (length of one cycle, stroke amount)
	2: Spline interpolation	
Multiple axes positioning data format	—	7 (start row of previous step) + 1 (row: total number of positioning data) + 1 (row: condition signal) + 1 (row: skip signal) + Number of sections + 2 (length of 1 cycle, stroke amount)
Digital cam switch data format	—	7 (start row of previous step) + Number of sections + 2 (length of one cycle, stroke length)

Common items

The common items as operation profile data are shown below.

○: Omission possible, ×: Omission not possible

Line No.	Column No.	Item	Omission	Setting range (Initial value)	Setting format	Description	Supported file version
1	1	Header tag	×	[HEADER]	String	Fixed string	0x0103
	2	File version	×	0x0103	Unsigned integer	Fixed value	0x0103
	3	For manufacturer 1	×	Arbitrary	Unsigned integer	To create a csv file externally, set 0.	0x0103
	4	For manufacturer 2	×	Arbitrary	String	To create a csv file externally, set 0.	0x0103
	5	For manufacturer 3	×	Arbitrary	Unsigned integer	To create a csv file externally, set 0.	0x0103
	6	For manufacturer 4	×	Arbitrary	Unsigned integer	To create a csv file externally, set 0.	0x0103
	7	For manufacturer 5	×	Arbitrary	Unsigned integer	To create a csv file externally, set 0.	0x0103

Line No.	Column No.	Item	Omission	Setting range (Initial value)	Setting format	Description	Supported file version
2	1	Profile ID	×	☞ Page 824 Operation Profile Data • Initial value: 0 (= automatic apply)	Unsigned integer	Specifies Profile ID. (Use only when carrying out automatic open when the power of the controller turns on.)	0x0103
	2	Periodic	○	☞ Page 824 Operation Profile Data	Integer	Specifies periodic.	0x0103
	3	Input absolute coordinate	○	☞ Page 824 Operation Profile Data	Integer	Specifies input absolute coordinate.	0x0103
	4	Output absolute coordinate	○	☞ Page 824 Operation Profile Data	Integer	Specifies output absolute coordinate.	0x0103
3	1	Operation profile data format	×	99: Cam data format 123: Cam data format for rotary cutter (Specifying a double-precision real number) 1000: Multiple axes positioning data format	Integer	Specifies operation profile data format.	0x0103
	2	Profile data type	○	1: Cam data • Initial value: 0 6: Digital output data 200: Multiple axes positioning data	Integer	Specifies the profile data type. ☞ Page 824 Operation Profile Data	0x0103
	3	Interpolation method specification	○	0: Linear interpolation 1: Section interpolation 2: Spline interpolation • Initial value: 0	Integer	Specifies the interpolation method between data.	0x0103
4	1	Resolution/number of coordinates	×	☞ Page 824 Operation Profile Data • Initial value: 0	Unsigned integer	Sets the resolution or the number of coordinates.	0x0103
5	1	Start point	○	*1 99: Valid for the cam data format (specified for each section, spline interpolation) • Initial value: 0	Real number	Specifies the start point.	0x0103
	2	Initial stroke amount	○	*1 99: Valid for the cam data format (specified for each section, spline interpolation) • Initial value: 0	Real number	Specifies the initial stroke amount.	0x0103
	3	Initial velocity	○	*1 99: Valid for the cam data format (specified for each section) • Initial value: 0	Real number	Specifies the initial velocity.	0x0103
	4	Initial acceleration	○	*1 99: Valid for the cam data format (specified for each section) • Initial value: 0	Real number	Specifies the initial acceleration.	0x0103
	5	Options	○	*2 • Initial value: 0	Unsigned integer	Defines for each operation profile data format.	0x0103
6	1	Number of sections	×	*2 • Initial value: 0	Unsigned integer	Specifies the number of sections for the data format that requires it. Specify "0" for the data format that does not require it.	0x0103

*1 Differs depending on the data format.

*2 Depends on the operation profile data format.

■(N-2)th line: Length per cycle

○: Omission possible

Line No.	Column No.	Item	Omission	Setting range (Initial value)	Setting format	Description	Supported file version
N-2	1	Length per cycle	○	0 or more*1	Real number	Specifies the length per cycle. Specify "0" for the data format that does not require it.	0x0103
	2	Unit setting	○	■Rules F: An arbitrary unit • Initial value: 0x0F	Unsigned integer	Specifies the unit of the length per cycle.	0x0103
	3	Unit character string	○	31 characters maximum • Initial value: "" ☞ Page 490 Units	String	Specifies an arbitrary character string when "an arbitrary unit" is set to the unit setting.	0x0103
	4	Minimum value per cycle (Ring counter lower limit value)*3	○	*2 • Initial value: 0.0	Real number	Defines for each operation profile data format. Specify "0" for the data format that does not require it.	0x0103
	5	Maximum value per cycle (Ring counter upper limit value)*3	○	*2 • Initial value: 0.0	Real number	Defines for each operation profile data format. Specify "0" for the data format that does not require it.	0x0103
	6	Time per cycle	○	0 or more*1	Real number	Specifies the time per cycle. Specify "0" for the data format that does not require it.	0x0103

*1 The maximum value differs depending on the data format.
*2 Differs depending on the data format.
*3 It is the item name for the digital cam switch.

■(N-1)th line: Stroke amount

○: Omission possible

Line No.	Column No.	Item	Omission	Setting range (Initial value)	Setting format	Description	Supported file version
N-1	1	Stroke amount	○	*1	Real number	Specifies the stroke amount. Specify "0" for the data format that does not require it.	0x0103
	2	Unit setting	○	■Rules F: An arbitrary unit • Initial value: 0x0F	Unsigned integer	Specifies the unit of stroke amount.	0x0103
	3	Unit character string	○	31 characters maximum • Initial value: "" ☞ Page 490 Units	String	Specifies an arbitrary character string when "an arbitrary unit" is set to the unit setting.	0x0103

*1 Differs depending on the data format.

■(N)th line: Common footer (EOF)

○: Omission possible, ×: Omission not possible

Line No.	Column No.	Item	Omission	Setting range (Initial value)	Setting format	Description	Supported file version
N	1	Last line tag	×	EOF: 3 characters	String	Fixed string	0x0103
N+1	1	File CRC	○	Arbitrary	Unsigned integer	Indicates the file CRC. To create a csv file externally, omit this line.	0x0103

Interpolation method specification (Interpolate): "0: Linear interpolation"

The following shows a case for specifying setting values below.

Line No.	Column No.	Item	Setting value
3	1	Operation profile data format	99: Cam data format
	3	Interpolation method specification (Interpolate)	0: Linear interpolation

■6th line: Number of sections

Specify 0.

■7th line or later: I/O data

×: Omission impossible

Line No.	Column No.	Item	Omission	Setting range (Initial value)	Setting format	Description	Supported file version
7	1	Input value (0th point)	×	☞ Page 496 Positioning Range	Real number	☞ Page 824 Operation Profile Data	0x0103
8	1	Output value (0th point)	×		Real number		0x0103
9	1	Input value (1st point)	×		Real number		0x0103
⋮							
For the number of coordinates × 2	1	Output value (nth point) (For the number of coordinates)	×	☞ Page 496 Positioning Range	Real number	☞ Page 824 Operation Profile Data	0x0103

Interpolation method specification (Interpolate): "1: Section interpolation"

The following shows a case for specifying setting values below.

Line No.	Column No.	Item	Setting value
3	1	Operation profile data format	99: Cam data format
	3	Interpolation method specification (Interpolate)	1: Section interpolation

■6th line: Number of sections

Specify the number of sections.

■7th line or later: Parameter

○: Omission possible, ×: Omission not possible

Line No.	Column No.	Item	Omission	Setting range (Initial value)	Setting format	Description	Supported file version
7	1	Cam curve types	×	Sets the cam curve with a value. For settable curves, refer to the following. ☞ Page 824 Operation Profile Data	Integer	☞ Page 824 Operation Profile Data	0x0103
	2	End point	×	☞ Page 824 Operation Profile Data	Real number		0x0103

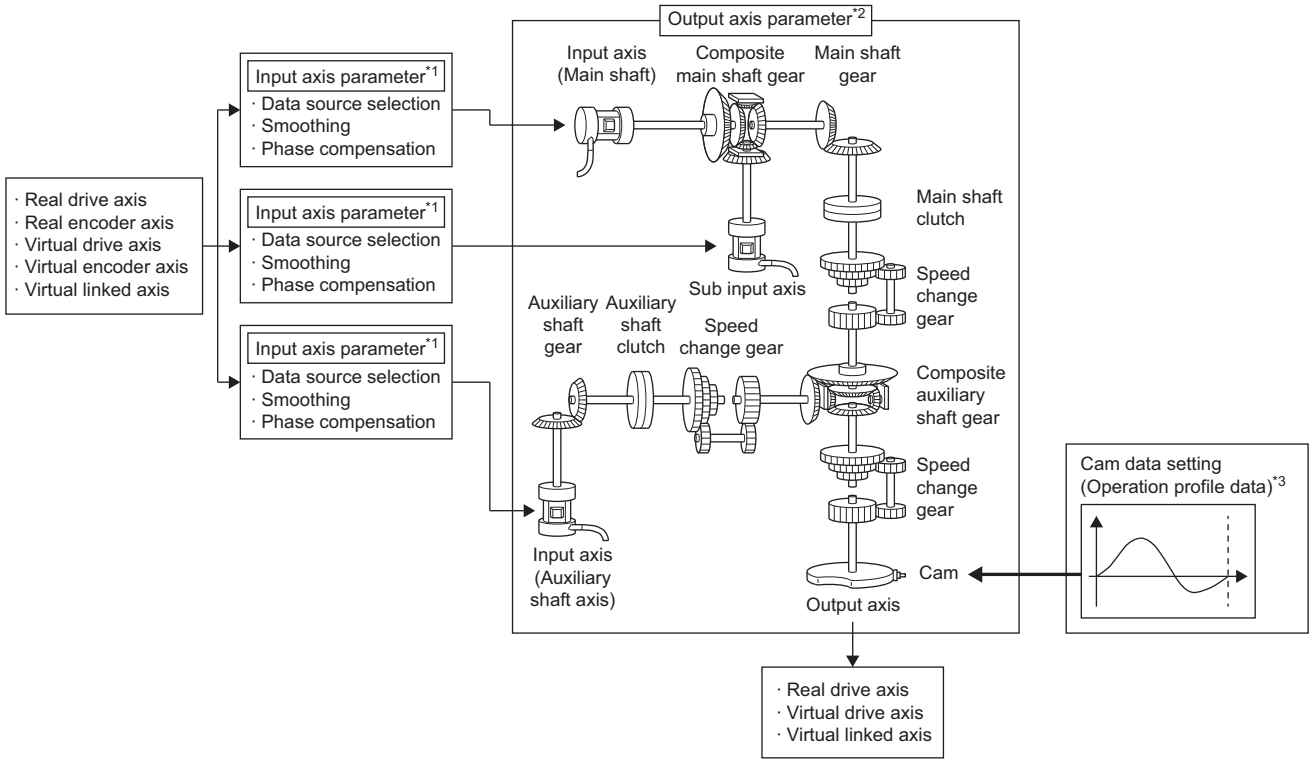
Notation for each setting format

Notation for each setting format is shown below.

Type		Notation	Example
Integer	Decimal	Directly enter a signed or unsigned decimal number.	123, +123, -123
	Hexadecimal	Add "0x" or "0X" before a hexadecimal number.	0xFF, 0XEAD
Real number	Decimal notation	Directly enter a signed or unsigned real decimal number with a decimal point.	2.34, +2.34, -2.34
	Exponential notation	Add "e" or "E" and a signed or unsigned exponent (decimal) at the end of the real number.	1.0e6, 1.0E-6
String		Directly enter a string.	ABC

33 ADVANCED SYNCHRONOUS CONTROL



33.1 Overview of Advanced Synchronous Control

Advanced synchronous control can be achieved using software instead of controlling mechanically with gears, clutches, speed change gears, cams, or others.

Advanced synchronous control synchronizes control with the input axis by setting parameters for advanced synchronous control and operation profile data and by starting MCv_AdvancedSync (Advanced Synchronous Control) on each output axis.

Set the input axes for advanced synchronous control and the filter settings using the input axis parameters.

Set the output axis for advanced synchronous control using the output axis parameters. The setting of the auxiliary axes and sub input axes, as well as the settings for gears, clutches, speed change gears, and cams are included under the output axis parameters.

*1 For details on input axes, refer to the following.
☞ Page 911 Input Axis Function

*2 For details on output axes, refer to the following.
☞ Page 920 Output Axis Function

*3 For details on cams, refer to the following.
☞ Page 964 Output axis module

Operation of this function at each status of system

○: Available, ×: Not available

System status	Input axis operation	Output axis operation
STOP	○*1	×
RUN	○	○
Moderate error	×	×
Major error	×	×

*1 The status of input axes can be monitored even when MCv_AdvancedSync (Advanced Synchronous Control) has not been started.

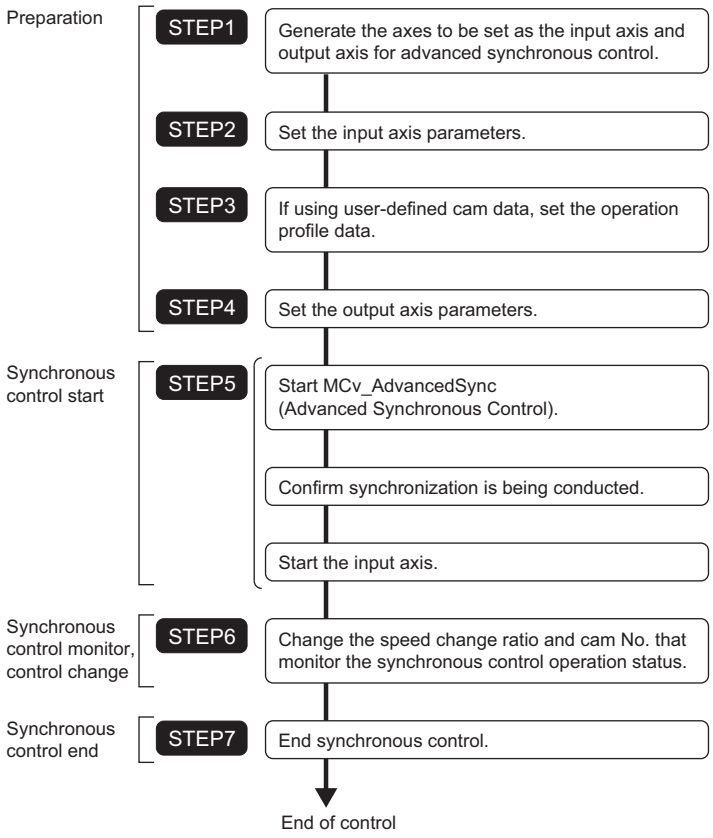
Relevant FBs



For details on motion control FBs, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

Motion control FB	Motion control FB	Name
MCv_AdvancedSync	Advanced synchronous control	Starts synchronization control according to the set advanced synchronous control setting.
MCv_AdvPositionPerCycleCalc	Advanced synchronous control current position per cycle calculation	Calculates the current position per cycle based on the set cam data.
MCv_AdvCamSetPositionCalc	Advanced synchronous control cam set position calculation	Calculates the cam set position based on the set cam data.

33.2 Control Details for Advanced Synchronous Control

This section describes the procedure for conducting advanced synchronous control.

Procedure for executing advanced synchronous control

This section describes the details of the procedure for conducting advanced synchronous control.

1. Generate the axes to be set as the input axis and output axis for advanced synchronous control.

In order to use advanced synchronous control, the axes to be set as the input axis and output axis must be generated.

Axes that can be set as an input axis and output axis are shown in the following table. For the specifications of each axis type, refer to the following.

☞ Page 443 Axis

☞ Page 466 Axis Assignment

○: Can be set, ×: Cannot be set

Axis type		Input axis	Output axis	Remarks
Real axis	Real drive axis	○	○	When control for multiple FBs (motion) is required, execute each FB with a virtual linked axis, and configure the axes to transmit the results (command) to the real drive axis.
	Real encoder axis	○	×	It is used as Master axis (Master). When it is used as Slave axis (Slave), Necessary Object Data Unset (error code: 1AF7H) occurs and it does not start.
Virtual axis	Virtual drive axis	○	○	Commands can be mainly created by positioning control or others.
	Virtual linked axis	○	○	Use as an intermediary axis to transmit a command to the real drive axis. When using multiple FBs (motion), assign them to virtual linked axes.
	Virtual encoder axis	○	×	It is used as Master axis (Master). When it is used as Slave axis (Slave), Necessary Object Data Unset (error code: 1AF7H) occurs and it does not start.

Generating the advanced synchronous control input axis and output axis will consume memory per each setting. Adjust the maximum RAM size (MotionControl_AdvancedSync_System.PrConst.AddonMemory.RamSizeMax) supported to match the system structure.

For memory usage, refer to the following.

☞ Page 910 System memory usage

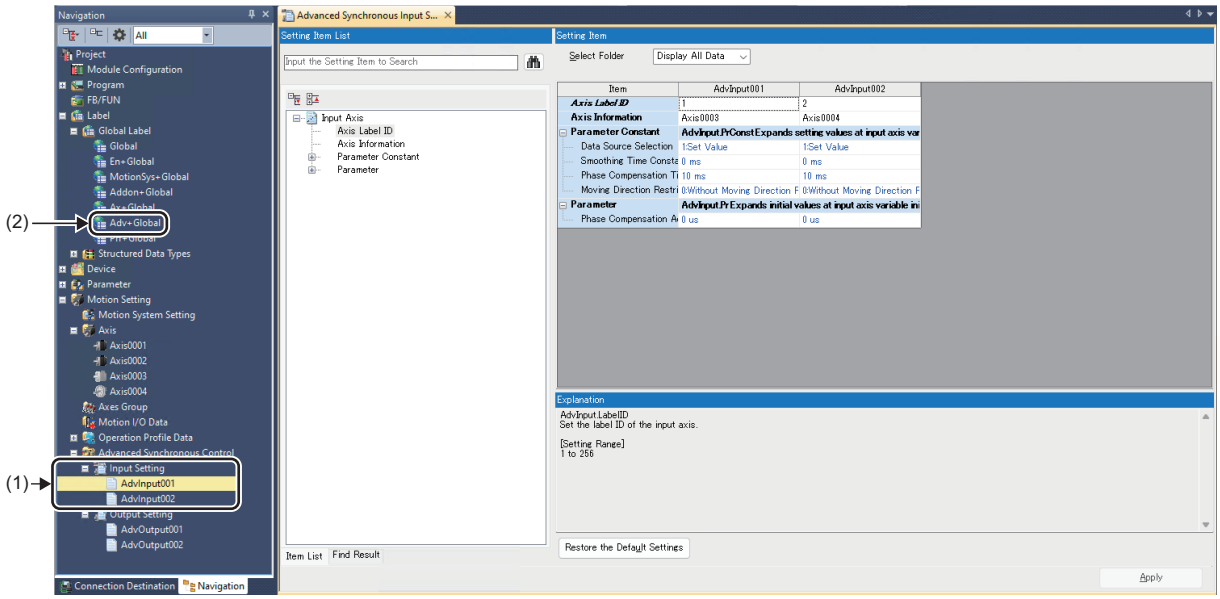
Also, if the axes set as an input axis or output axis are using an absolute position system, backup RAM will be consumed. For backup RAM usage for each setting, refer to the following.

☞ Page 991 Backup data management for advanced synchronous control

2. Set the input axis parameters.

Generate an input axis from "Input Setting" (1) under "Advanced Synchronous Control" in GX Works3.

When an input axis is generated, ADV_INPUT type labels are generated in global label "Adv+Global" (2).*1



Set the axis to be used as an input axis in the Axis information (AdvInputName.Axis) of the input axis under input settings. It is not possible to set the same axis to the axis information of different input axes. For details on settable axis types, refer to step 1.

For details on input settings, refer to the following.

☞ Page 911 Input Axis Function

*1 ADV_INPUT type labels defined in local label cannot be used in advanced synchronous control.

Navigation window ⇨ [Motion Setting] ⇨ [Advanced Synchronous Control] ⇨ [Input Setting]

3. Set cam data.

Set the cam data from the operation profile data.

Set this when using a cam whose slave axis synchronizes its position with the master axis according to the cam data and output settings.

Before using the cam function, the cam table must be transmitted to the open area and made controllable. For details on transmitting a cam table to the open area and data types that can be controlled by the cam operation, refer to the following.

☞ Page 964 Output axis module

☞ Page 972 Cam function

☞ Page 824 OPERATION PROFILE DATA FUNCTION

Set the set operation profile data to "Cam No." (AdvOutputName.Pr.Cam.CamNo) of the "Output Setting". When using a "Cam No." other than "0", it is required to install the add-on "ProfileControl" in advance. If MCv_AdvancedSync (Advanced Synchronous Control), MCv_AdvPositionPerCycleCalc (Advanced Synchronous Control Current Position Per Cycle Calculation), or MCv_AdvCamSetPositionCalc (Advanced Synchronous Control Cam Set Position Calculation) is started without "ProfileControl" installed, the following errors occur.

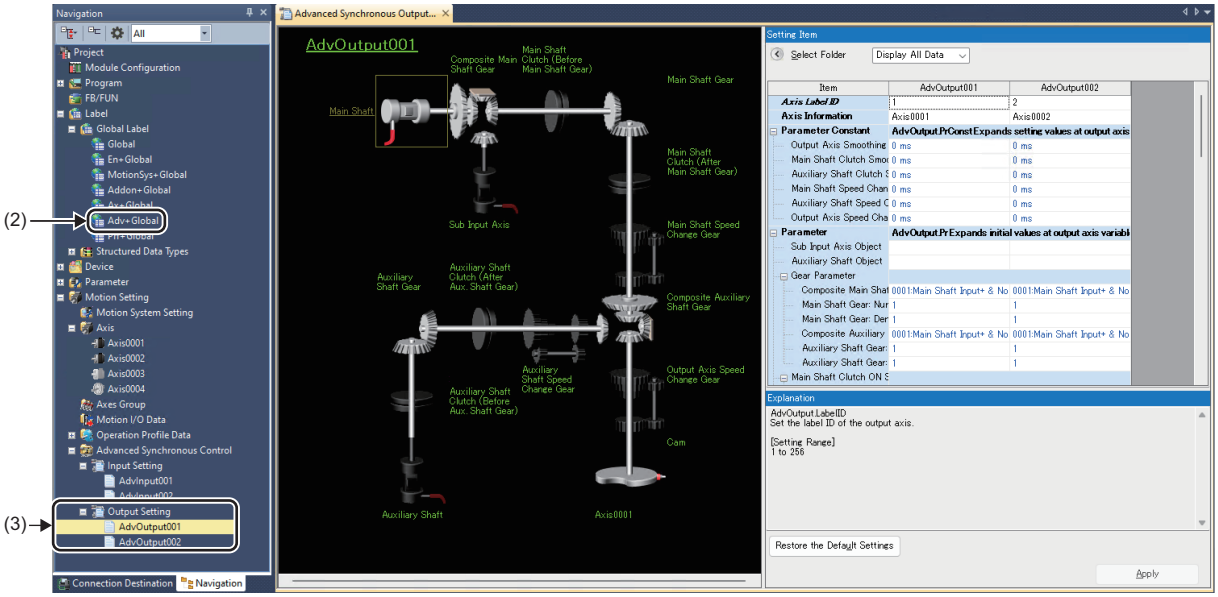
Motion control FB	Error code
MCv_AdvancedSync (Advanced Synchronous Control)	Add-on Acquisition Failure (error code: 1AF6H)
MCv_AdvPositionPerCycleCalc (Advanced Synchronous Control Current Position Per Cycle Calculation)	Add-on Acquisition Failure (error code: 1BCBH)
MCv_AdvCamSetPositionCalc (Advanced Synchronous Control Cam Set Position Calculation)	

4. Perform the output settings.

Generate an output axis from "Output Setting" (3) under "Advanced Synchronous Control" in GX Works3.

When an output axis is generated, ADV_OUTPUT type labels are generated in global label "Adv+Global" (2). *1

Set the axis to be used as an output axis in the Axis information (AdvOutputName.Axis) of the output axis under "Output Setting". It is not possible to set the same axis to the axis information of different output axes.



By setting the input axis set in step 1 to "Auxiliary axis" (AdvOutputName.Pr.AuxAxis) and "Sub input axis" (AdvOutputName.Pr.SubAxis), the auxiliary axis and sub input axis inputs can be combined to the master axis.

For details on output settings, refer to the following.

☞ Page 920 Output Axis Function

*1 ADV_OUTPUT type labels defined in local label cannot be used in advanced synchronous control.

Navigation window ⇨ [Motion Setting] ⇨ [Advanced Synchronous Control] ⇨ [Output Setting]

5. Start synchronous control.

Set the input axis and output axis set in steps 1 to 3 to the MCv_AdvancedSync (Advanced Synchronous Control) input/output variables.

- Input axis: Master axis (Master)
- Output axis: Slave axis (Slave)

If using analysis mode, set the following input variables.

- Synchronous control analysis mode setting (Options (Options): Bit 16)

Start synchronous control by starting MCv_AdvancedSync (Advanced Synchronous Control). For details on starting and confirmation during synchronization, refer to the following.

☞ Page 900 Starting/stopping for advanced synchronous control

6. Change the synchronous control monitor and control.

Monitors such as the current position per cycle for advanced synchronous control can be checked in the Output axis monitor data (AdvOutputName.Md.).

The advanced synchronous control gear, clutch, speed change gear, and synchronous control change function can be used in the output axis control data (AdvOutputName.Cd) and the output axis parameters (AdvOutputName.Pr) of the output axis while MCv_AdvancedSync (Advanced Synchronous Control) is running.

For details on output axis functions, refer to the following.

☞ Page 920 Output Axis Function

7. Stop synchronous control.

To stop the operation, use the following method.

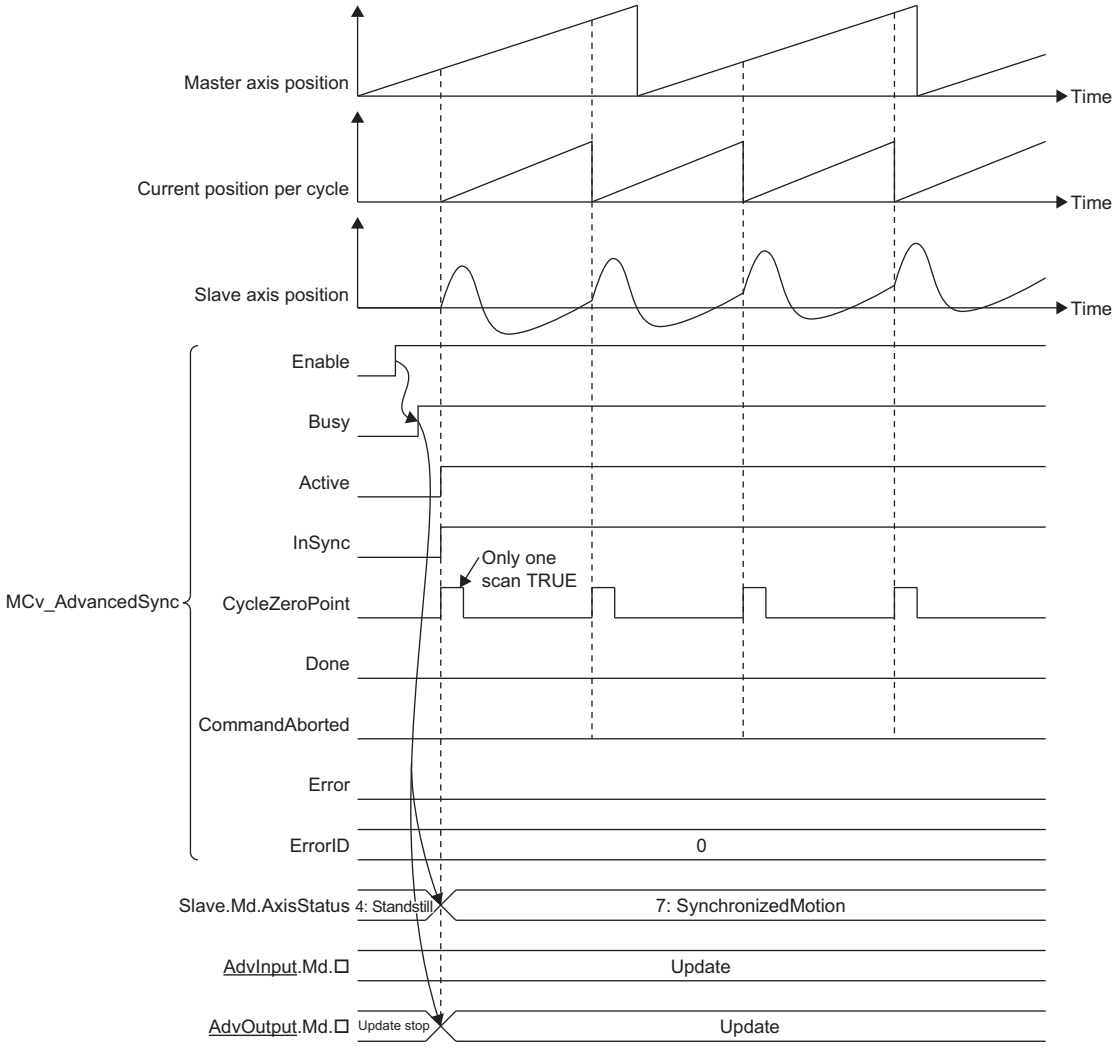
- Change MCv_AdvancedSync (Advanced Synchronous Control) Enable (Enable) from TRUE to FALSE.
- Start MC_Stop (Forced Stop).

Advanced synchronous control can be ended even while the input axis is in operation. However, as the output axis under stop operation is not in synchronization, stop the operation of the input axis before ending.

For details on stopping advanced synchronous control, refer to the following.

☞ Page 900 Starting/stopping for advanced synchronous control

Starting/stopping for advanced synchronous control



This section describes how to start and stop the operation for advanced synchronous control.

Operation when starting

To start advanced synchronous control, set MCv_AdvancedSync (Advanced Synchronous Control) Enable (Enable) to TRUE. Synchronous control can only be started when the slave axis Axis status (AxisName.Md.AxisStatus) is "4: Standby (Standstill)". Upon starting advanced synchronous control, the slave axis Axis status (AxisName.Md.AxisStatus) changes to "7: During synchronous operation (SynchronizedMotion)". When synchronous control is started, if the status is not "4: Standby (Standstill)", the slave axis Axis status (AxisName.Md.AxisStatus) will change to "1: Stopping on error (ErrorStop)" and Start not possible (error code: 1AFCH) will occur.

The Input axis monitor data (AdvInputName.Md.☐) will continuously be updated regardless of whether synchronous control has started.

The Output axis monitor data (AdvOutputName.Md.☐) will be updated after the slave axis Axis status (AxisName.Md.AxisStatus) changes to "7: During synchronous operation (SynchronizedMotion)".

Stop operation

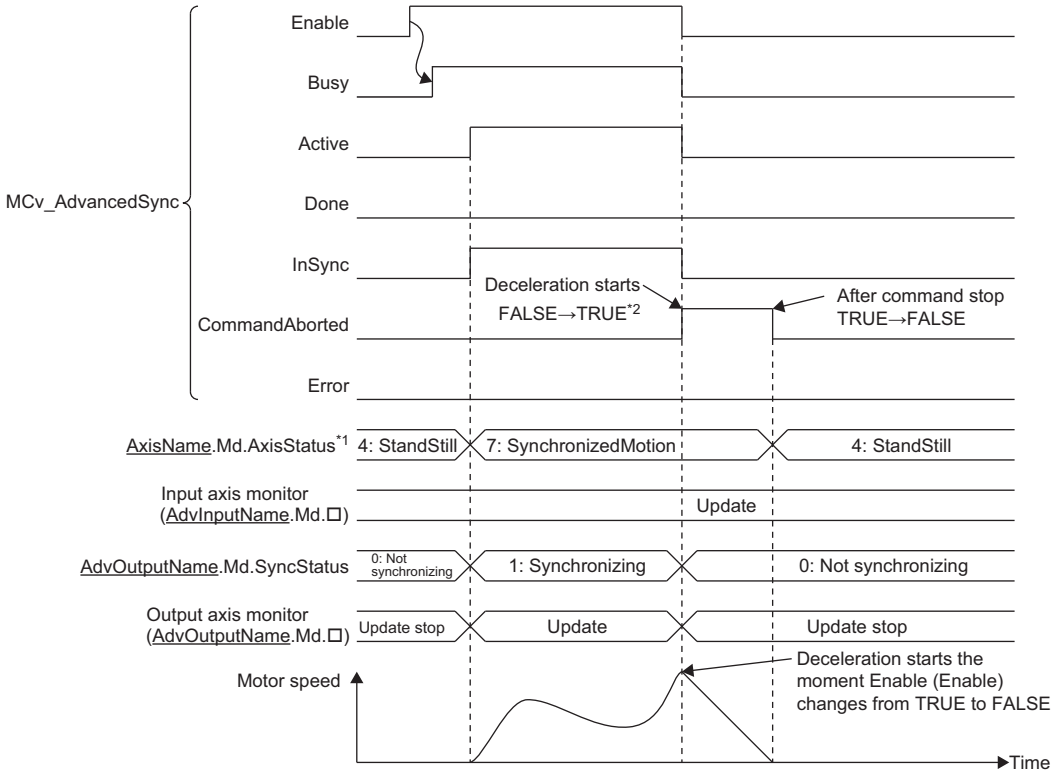
When MCv_AdvancedSync (Advanced Synchronous Control) Enable (Enable) is set to FALSE, or if a stop cause occurs on the axis set in axis information of the output axis, the Slave axis (Slave) immediately stops or decelerates to a stop according to the stop cause and stopping process.

The following shows stop causes during axis operation and the process when each cause occurs.

Stop cause*1	Stopped axis	Axis status (AxisName.Md.AxisStatus)		Stop process*2
		During deceleration stop	After stopping	
Enable (Enable) is set to FALSE during synchronous control by MCv_AdvancedSync (Advanced Synchronous Control)	Each axis	7: During synchronous operation (SynchronizedMotion)	4: Standby (Standstill)	Deceleration stop/immediate stop (Follows Stop Selection at Stop Cause Occurrence (AxisName.Pr.StopMode_General))

*1 For other stop causes, refer to the following.
☞ Page 584 Stop causes during axis operation

*2 For each operation of stopping processes, refer to the following.
☞ Page 586 Stop processes for single axis

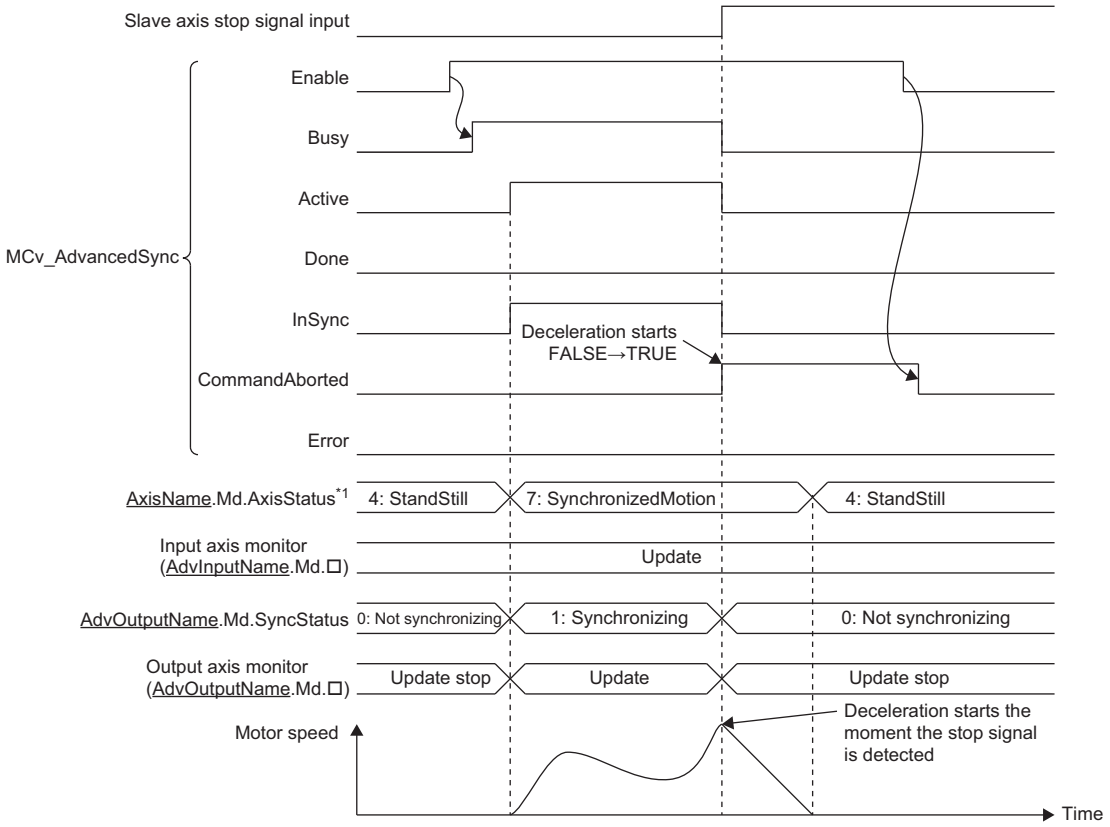


After the stop cause occurs, an Input axis monitor data (AdvInputName.Md.☐) update will not stop, but an Output axis monitor data (AdvOutputName.Md.☐) update will stop and the values at the moment when the stop cause occurred will be retained. The Output axis monitor data (AdvOutputName.Md.☐) will be updated the next time MCv_AdvancedSync (Advanced Synchronous Control) is executed.

Point

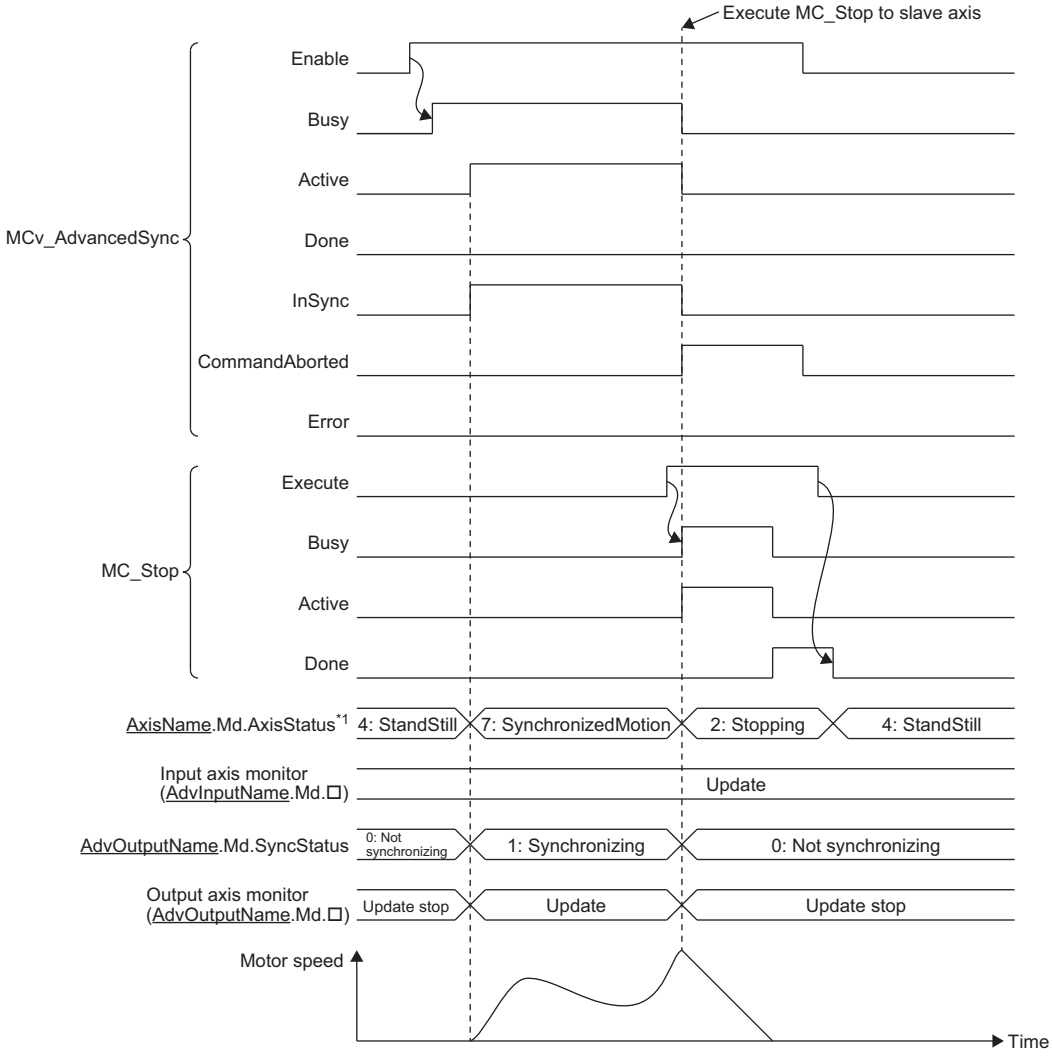
To stop using the deceleration set in Deceleration (Deceleration) under MCv_AdvancedSync (Advanced Synchronous Control), set the Stop Selection at Stop Cause Occurrence (AxisName.Pr.StopMode_General) to "2: Keep Current Acceleration/Deceleration (KeepCurrentAcc)".

Timing charts showing what happens when a stop cause occurs are shown below.



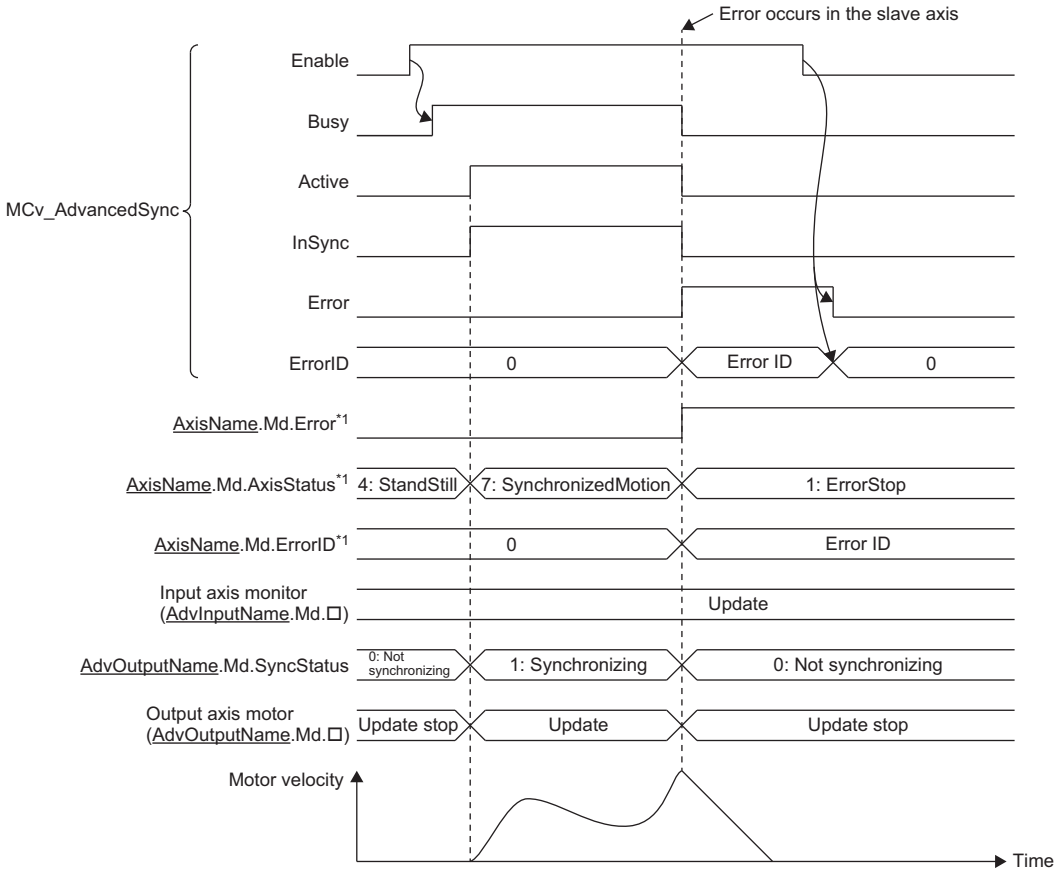
■When MCv_AdvancedSync (Advanced Synchronous Control) Enable (Enable) is set to FALSE during advanced synchronous control

*1 This is the state of Slave axis (Slave).



*2 If Immediate stop is selected, only one scan will be TRUE.

■When a slave axis stop signal is detected during advanced synchronous control



*1 This is the state of Slave axis (Slave).

■When stop cause (MC_Stop (Forced Stop) execution/stop signal detection) occurs during advanced synchronous control

*1 This is the state of Slave axis (Slave).

■When a stop cause (Slave axis error, Forced stop) occurs during advanced synchronous control

*1 This is the state of Slave axis (Slave).

Precautions

- During execution of MCv_AdvancedSync (Advanced Synchronous Control), if a stop cause occurs on the axis set in the input axis information of the Master axis (Master), Auxiliary axis (AdvOutputName.Pr.AuxAxis), or Sub input axis (AdvOutputName.Pr.SubAxis), the Slave axis (Slave) will continue control using commands transmitted from the input axis. The Slave axis (Slave) axis status will not change. Also, if a stop cause occurs in the axis set in the output axis Axis information (AdvOutputName.Axis), it will not affect the axis set in the input axis Axis information (AdvInputName.Axis).
- When MCv_AdvancedSync is started, Master axis and slave axis cyclic reference (error code: 1AADH) occurs when the following conditions are satisfied.

Conditions
When linking multiple axes with MCv_AdvancedSync (Advanced Synchronous Control), and setting the Master axis (Master), Auxiliary axis (AdvOutputName.Pr.AuxAxis), and Sub input axis (AdvOutputName.Pr.SubAxis) to the Slave axis (Slave) of single axis synchronous control FB of the back part.
When linking 257 or more single axis synchronous control FBs

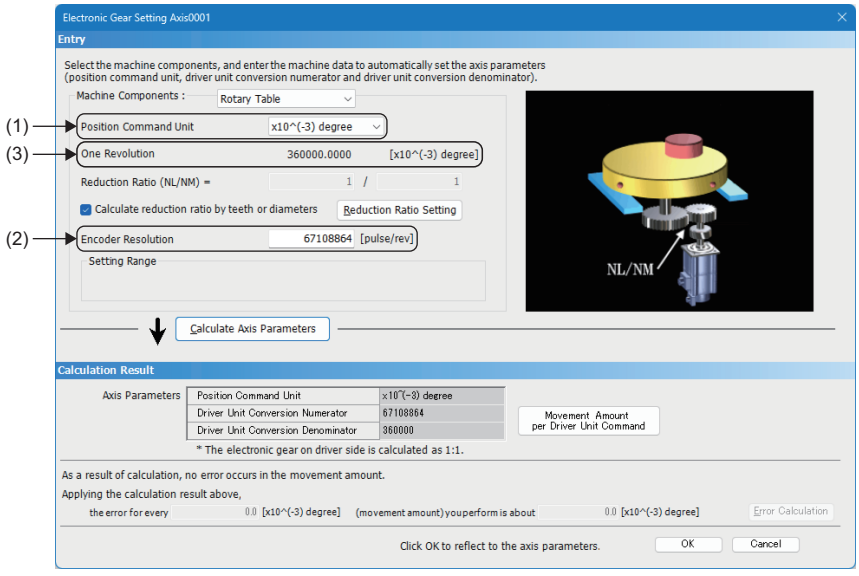
- When the Master axis (Master), Auxiliary axis (AdvOutputName.Pr.AuxAxis), and Sub input axis (AdvOutputName.Pr.SubAxis) change to servo OFF due to a servo alarm or a forced stop, an unexpected operation of the Slave axis (Slave) may occur. Therefore, stop MCv_AdvancedSync (Advanced Synchronous Control) using MC_Stop (Forced Stop).
- If an input axis is operated during the analyzing of MCv_AdvancedSync (Advanced Synchronous Control) startup (until the Slave axis (Slave) axis status (AxisName.Md.AxisStatus) becomes "7: During synchronous operation (SynchronizedMotion)"), the change amount based on current value change and the movement amount of the input axis during analyzing is reflected immediately after synchronous control starts. As the output axis may suddenly accelerate depending on the change amount and movement amount of the input axis, start the operation of the input axis after checking synchronous control is in operation.
- If the member variable setting value of ADV_INPUT or ADV_OUTPUT that imports setting values during synchronous control is changed to a value out of range while MCv_AdvancedSync (Advanced Synchronous Control) is being executed, Out of Advanced Synchronous Control Variable Range Warning (error code: 0D3FH) occurs, and control will continue using the setting values before the change. If the member variable setting value of ADV_INPUT or ADV_OUTPUT is out of range when MCv_AdvancedSync is started, Out of Parameter Range (Advanced Synchronous Control Input Axis) (error code: 1A65H) or Out of Parameter Range (Advanced Synchronous Control Output Axis) (error code: 1A66H) occurs, and advanced synchronous control will not start.
- Operation cycle mismatch (error code: 1B29H) occurs when the following conditions are satisfied when MCv_AdvancedSync is started. Even if MCv_SyncOperationCycles (Synchronize Control Operation Cycle) is enabled, Operation cycle mismatch (error code: 1B29H) will occur at startup of MCv_AdvancedSync if the following conditions are satisfied.

Conditions
When the control operation cycle is different between the Master axis (Master), Auxiliary axis (AdvOutputName.Pr.AuxAxis), Sub input axis (AdvOutputName.Pr.SubAxis), and Slave axis (Slave)
When the control operation cycle of the output axis and the refresh cycle of the clutch signal are different

Advanced synchronous control precautions

This section describes precautions when using advanced synchronous control.

Decimal points



- The decimal point range guaranteed for the input axis and output axis together is up to 5 decimal places. When setting the units, set the appropriate unit for the system to the Position command unit (AxisName.Pr.Unit_Position).
  When control is performed in units of degrees, to accurately control values equal to or less than the decimal "0.00001" using control, set the position command unit to "$\times 10^{-3}$ degree" or "$\times 10^{-6}$ degree" instead of "degree". As a result, the value of "0.00001" can be handled as "10.0" in terms of control, meaning it can be controlled accurately.

Ex.

Setting in units of degrees

Accuracy required by the system	Value to set for axis parameters*1			Monitor display
	(1) Position Command Unit (AxisName.Pr.Unit_Position)	(2) Driver Command Unit Numerator (AxisName.Pr.Drive_Unit ConvRatioNum)	(3) Driver Command Unit Denominator (AxisName.Pr.Drive_Unit ConvRatioDen)	
360000000360.00000 [degree]	H00410000 degree $\times 10^{-0}$	67108864 (Servo motor resolution)	360	360.00000... [degree]
360.00000000 [degree]	HFD410000 degree $\times 10^{-3}$		360000	360000.00000... [10^(-3) degree]
360.00000000000 [degree]	HFA410000 degree $\times 10^{-6}$		360.00000360000000	360000000.00000... [10^(-6) degree]

*1 Set axis parameters in the "Electronic Gear Setting" window. The window can be displayed as follows: Navigation window ⇨ [Motion Setting] ⇨ [Axis] ⇨ Target axis ⇨ [Basic Parameter] ⇨ Click the [...] button in [Position Command Unit].

- If the position command unit of the axis specified as an output axis has been set to "$\times 10^{-6}$degree", in addition to operating the slave axis by synchronous control restoration, it is possible to exceed the velocity limit value with the axis set as the output axis. If the velocity limit value is exceeded, move the set position of the axis set as the output axis in advance to a position close to the restoration position, or change the position command unit to a large unit such as "$\times 10^{-3}$degree".
- As the guaranteed range for decimals is up to 5 decimal places, the numbers of the current position of the axis set as the input axis are truncated after the 5th decimal place. In addition, if a value with more than 5 decimal places is set for a parameter or control data variable with a double-precision real number data type, the values after the 5th decimal place are ignored.
- If double-precision real numbers are monitored with the engineering tool, any values after the 5th decimal place may differ from the actual values.

Ex.

If the current position per cycle is in "180.00000" position

The monitor may display this as "179.999999...".

Smoothing

■Import timing

The smoothing time constant becomes enabled when the system is started. To reflect any changed values, a system restart is required.

■Smoothing time constant setting value and operation cycle setting

When the smoothing time constant is set to the maximum value (5000 [ms]), in addition to the operation cycle being less than or equal to 125 [μs], there will be restriction on the movement amount that can be processed per operation cycle. The relationship between the operation cycle and movement amount is shown in the following table.

Operation cycle [μs]	Movement amount per operation cycle when the smoothing time constant is 5000 [ms]
125	-1073741824.0 to 1073741823.0
250 or more	-2147483648.0 to 2147483647.0

If a value larger than the movement amount corresponding to the operation cycles in the above table is input into one operation cycle, Advanced Synchronization Control Operation Overflow Warning (event code: 00D3EH) occurs on the input axis and Advanced Synchronization Control Operation Overflow (error code: 1B23H) occurs on the output axis.
The filter level can be calculated by the following formula. Any decimal values rounded to the nearest integer. However, if the result is rounded to "0", the filter level will operate using level 1.
Filter level = (smoothing time [ms]) ÷ operation cycle [ms]

■Smoothing function memory usage

- When using the smoothing function, the longer the total of the smoothing time constant used by advanced synchronous control, the more system memory the add-on MotionControl_AdvancedSync consumes. The overall smoothing time is calculated using the following formula.
  Total smoothing time = Total smoothing time constant (AdvInputName.PrConst.SmoothingTimeConstant) + Total Master axis clutch smoothing time constant (AdvOutputName.PrConst.MasterClutchSmoothingTimeConstant) + Total Auxiliary axis clutch smoothing time constant (AdvOutputName.PrConst.AuxClutchSmoothingTimeConstant) + Total Output axis smoothing time constant (AdvOutputName.PrConst.SmoothingTimeConstant) + Total Master axis speed change gear smoothing time constant (AdvOutputName.PrConst.MasterSpeedChangeGearSmoothingTimeConstant) + Total Auxiliary axis speed change gear smoothing time constant (AdvOutputName.PrConst.AuxSpeedChangeGearSmoothingTimeConstant) + Total Output axis speed change gear smoothing time constant (AdvOutputName.PrConst.OutSpeedChangeGearSmoothingTimeConstant)
- The smoothing function secures memory used by the smoothing process at power ON. Memory usage can be calculated using the following formula.
  Memory usage = Filter level × 8 bytes
- Operation when smoothing memory is insufficient
  Depending on the smoothing time constant setting, Advanced Synchronous Control Smoothing Memory Shortage (error code: 1A0DH) or Advanced Synchronous Control Add-on Memory Shortage (error code: 1A0CH) will occur at startup. If an error occurs, reduce the smoothing time constant used by advanced synchronous control, or set the add-on MotionControl_AdvancedSync parameter (AddonSystem.PrConst.AddonMemory) to satisfy the required memory capacity.

Writing to the controller

Deleting an axis or axes group variable by writing to the controller (including online program change) causes an Invalid write to the controller (error code: 3408H). Then, the motor will immediately stop due to the setting. Note that immediate stop may damage the machine.

Combination with other functions

■External signal selection

The current position per cycle under advanced synchronous control can be referred to by specifying [AXIS] for data type of the TARGET_REF structure target (Target). Set "@AdvSyncPosPerCyc" for "Target modification (string starting with @)".
The following shows data to be referred to by using the MC_SOURCE type enumerator set in Data name.
○: Can be set, ×: Cannot be set

MC_SOURCE type enumerator	Description	Modification
		@AdvSyncPosPerCyc
1: Set Value (mcSetValue)	Current position per cycle in the previous operation cycle of the output axis	○
2: Actual Value (mcActualValue)	External Signal Selection Incorrect (error code: 1BD6H) (detail code: H0002) occurs.	×
101: Latest Set Value (mcLatestSetValue)	Current position per cycle in this operation cycle of the output axis	○
102: Latest Actual Value (mcLatestActualValue)	External Signal Selection Incorrect (error code: 1BD6H) (detail code: H0002) occurs.	×

The data is updated as a ring counter. The range of the ring counter is 0.0 to (length per cycle - 0.00001).

Precautions

Do not change the length per cycle with Length per cycle change setting (AdvOutputName.Pr.Cam.LengthPerCycleChange) for the output axis for which the current position per cycle is referred to with the touch probe or digital cam switch during synchronous control. If the length per cycle is changed, correct data may not be referred to.

■Touch probe

When latching the Input axis variables (AdvInputName.☐) and Output axis variables (AdvOutputName.☐) using MC_TouchProbe (Touch Probe), latch is possible by specifying the data type to [VAR]. However, the latch data stores a value delayed by one operation cycle.
In addition, latch data estimations do not take into account any values exceeding the permissible value.

■Digital cam switch

When referring to the Input axis variables (AdvInputName.☐) and Output axis variables (AdvOutputName.☐) using the data source of MC_DigitalCamSwitch (digital cam switch), the reference is possible by specifying the data type to [VAR]. However, a value delayed by one operation cycle is stored as the value referred to by the data source.
In addition, data source estimations do not take into account any values exceeding the permissible value.

■Synchronous control function

The following motion control FB cannot be combined with advanced synchronous control.
To change the cam reference position, the current position per cycle, and current position per cycle after main shaft/auxiliary shaft gear during synchronous control, use the synchronous control change function.

- MCv_ChangeCycle (Current Position Change Per Cycle)

Required object data

Refer to the required object data for the output axis function.

☞ Page 989 Required object data

Relevant add-ons

The following add-ons are required to use this function.

Item	Add-on
Required	• baseSystem • Axis • MotionEngine • MotionControl_General • MotionControl_AdvancedSync • MotionControl_Sync
When using synchronous control initial position function	AbsSystem
When using operation profile data	ProfileControl
When using an external input signal with a clutch	SignalIO

System memory usage

■RAM usage

- When there are no input settings, output settings, and motion control FBs, 270 KB of memory will be used. The memory usage for input settings, output settings, and each motion control FB is shown below. Change the add-on MotionControl_AdvancedSync parameter (AddonSystem.PrConst.AddonMemory) where necessary.

Axis type	RAM usage
Input axis	2.7KB
Output axis	8.2KB
MCv_AdvancedSync (Advanced Synchronous Control)	1.0KB

- For memory usage when using smoothing, refer to the following.

  ☞ Page 908 Smoothing function memory usage

■When the add-on memory capacity is insufficient

When the memory used for add-ons is insufficient, Add-on memory insufficient (error code: 340CH) occurs. If an error occurs, set the add-on MotionControl_AdvancedSync parameter (AddonSystem.PrConst.AddonMemory) to satisfy the required memory capacity.

The add-on memory free space and filter function usage can be checked with System Memory Usage (AddonSystem.Md.AddonMemory).

■Backup RAM usage

For backup RAM usage, refer to the following.

☞ Page 991 Backup data management for advanced synchronous control

Buffer mode

For the buffer modes that can be specified with MCv_AdvancedSync (Advanced Synchronous Control), refer to the following.

☞ Page 555 Buffer mode that can be set

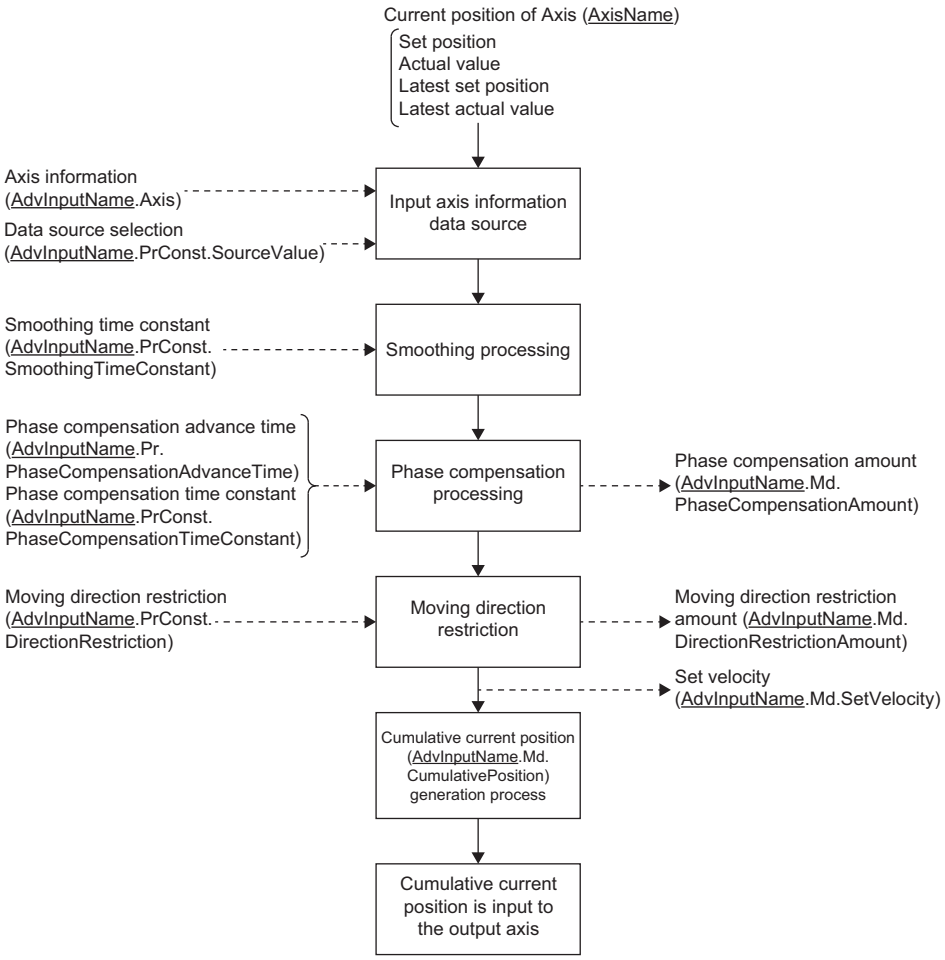
33.3 Input Axis Function

In GX Works3, configure the input settings for advanced synchronous control and generate and initialize the input axes necessary for advanced synchronous control. Any set axes will be assigned to the global label data as an input axis variable. Input axes are defined as an axis variable consisting of monitor information such as parameter information and current positions.

As the input axis settings are enabled after power ON, the status of input axes can be monitored even when MCv_AdvancedSync (Advanced Synchronous Control) has not been started.

When a warning or error occurs in the input axis, the warning or error is stored in the axis set in the input axis Axis information (AdvInputName.Axis).

The input axis functions are shown below.



Function	Description	Application
Type setting	Sets the axis and data source used for the input axis.	Set the axis to transmit to the advanced synchronous control output axis and its input values.
Smoothing	Smoothing processing will be conducted for the input value of the axis set in type setting.	It is possible to suppress the velocity change by smoothing processing when "Actual Value" or "Latest Actual Value" is set as the input value in the data source. However, the input response is delayed by the set time due to the smoothing process.
Phase compensation	Phase compensation processing will be conducted for the input values of the axis set in type setting.	When a real drive axis or real encoder axis is set to the input axis, a phase delay occurs between the input axis and output axis motor shaft end. The phase compensation function is used to prevent phase deviation. For phase compensation of the input axis delay time, set the delay time peculiar to the system to the input axis Phase compensation advance time (AdvInputName.Pr.PhaseCompensationAdvanceTime).*1
Moving direction restriction	Moving direction restriction will be applied to the input values of the axis set in type setting.	When "Actual Value" or "Latest Actual Value" is set as the input value in the data source, it is possible to prevent reverse operation due to mechanical vibration or other factors.
Monitor	Monitors the input axis. Input axis monitor values are stored in the following monitor data. • Active status (AdvInputName.Md.ActiveStatus) • Cumulative current position (AdvInputName.Md.CumulativePosition) • Set velocity (AdvInputName.Md.SetVelocity) • Phase compensation amount (AdvInputName.Md.PhaseCompensationAmount) • Moving direction restriction amount (AdvInputName.Md.DirectionRestrictionAmount)	When the status of the input axis is monitored, this is described on the program.

*1 For the delay time peculiar to the system, refer to the following.

☞ Page 1016 Phase compensation function

After the input axis is generated, specify the input axis Axis information (AdvInputName.Axis) to the Master axis (Master) of the MCv_AdvancedSync (Advanced Synchronous Control). If using an auxiliary shaft and a sub input axis, specify the input axis Axis information (AdvInputName.Axis) to the Auxiliary shaft object (AdvOutputName.Pr.AuxAxis) and the Sub input axis object (AdvOutputName.Pr.SubAxis).

The relationship between the axis current position set in the input axis Axis information (AdvInputName.Axis) and each input axis function is shown below.

Input axis initialization timing

The input axis variables are initialized at the following timing.

Timing	Process
Power ON CPU module reset	Refers to the global label data, and initializes all set input axis variables.
At PLC READY OFF → ON	■Uninitialized axes Refers to the global label data and initializes all axis variables. ■Initialized axes When the parameter error occurs at loading, the axis is not deleted. In this case, the READY does not turn on. For the label initialization processing when the PLC READY turns off to on, refer to "Label initialization function" in the following manual. MELSEC MX Controller MX-R Model Programming Manual

Input axis position command unit

The input axis position command unit is the Position command unit (AxisName.Pr.Unit_Position) and the Position command unit string (AxisName.Pr.Unit_PositionString) of the axis set in the input axis Axis information (AdvInputName.Axis).
In addition, the position command unit of the input axis and output axis during synchronous control will not affect control. The result of the calculation performed for the position information of the input axis which has no unit information is used as the command of the output axis.
Refer to the explanation of each monitor data for details on input axis monitor display units.

Input axis positioning range

Regardless of the Ring counter upper limit value (AxisName.PrConst.RingCount_UpperValue) or Ring counter lower limit value (AxisName.PrConst.RingCount_LowerValue) of the axis positioning range set in the input axis Axis information (AdvInputName.Axis), the input axis Cumulative current position (AdvInputName.Md.CumulativePosition) will be within the following range.

Positioning range
-10000000000.0 ≤ Positioning range < 10000000000.0

Input axis relevant variables

Input axis (AdvInputName.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
LabelID	Axis label ID	At system start	WORD (UINT)	1 to 256	0
Axis	Axis information		AXIS_REF	—	—

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Axis label ID(AdvInputName.LabelID)

Sets the label ID of the input axis.

Stores the variable ID of the input axis for advanced synchronous control.

The range is 1 to 256.

■Axis information (AdvInputName.Axis)

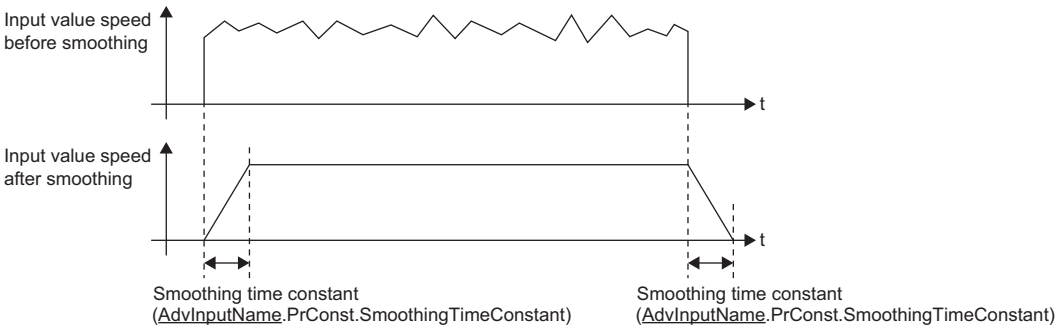
- Sets the Axis information (AxisName.AxisRef) of the axis that will be the input axis for advanced synchronous control. Up to 256 input axes can be generated.
  It is not possible to set the same axis to the axis information of different input axes. If it is set, Advanced Synchronous Control Input Axis Incorrect (error code: 1A0EH) will occur.
- Do not set the Axis information (AxisName.AxisRef) of an axis defined in local labels. If it is set, input axes will not be generated.

Input axis parameter constant (AdvInputName.PrConst.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
SourceValue	Data source selection	At system start	INT (MC_SOURCE)	• 1: Set Value (mcSetValue) • 2: Actual Value (mcActualValue) • 101: Latest Set Value (mcLatestSetValue) • 102: Latest Actual Value (mcLatestActualValue)	1: Set Value (mcSetValue)
SmoothingTimeConstant	Smoothing time constant		WORD (UINT)	0 to 5000 [ms]	0 [ms]
PhaseCompensationTimeConstant	Phase compensation time constant		WORD (UINT)	0 to 65535 [ms]	10 [ms]
DirectionRestriction	Moving direction restriction		INT (MC_INPUT_DIRECTION)	• 0: Without movement direction restriction (NoDirectionRestriction) • 1: Enable only for current position increase direction (mcPositiveDirection) • 2: Enable only for current position decrease direction (mcNegativeDirection)	0: Without moving direction restriction (NoDirectionRestriction)

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Data source selection (AdvInputName.PrConst.SourceValue)

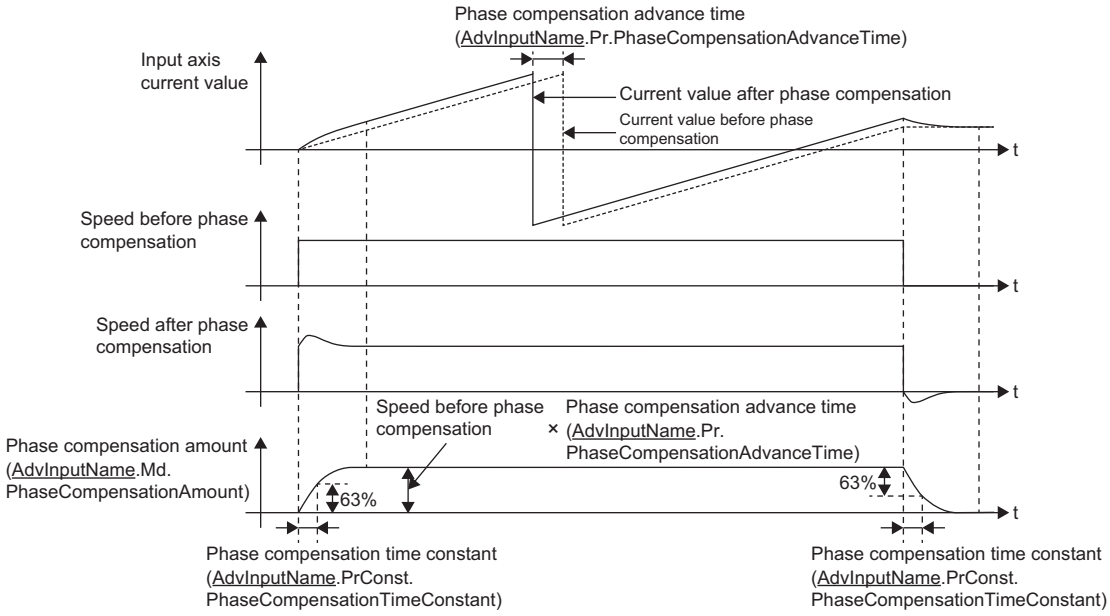


Set the input axis data source to be referenced in advanced synchronous control.

Setting value	Description
1: Set Value (mcSetValue)	Uses the set position of the axis specified to the input axis in the previous operation cycle.
2: Actual Value (mcActualValue)	Uses the actual position of the axis specified to the input axis in the previous operation cycle.
101: Latest Set Value (mcLatestSetValue)	Uses the set position of the axis specified to the input axis in the current operation cycle.
102: Latest Actual Value (mcLatestActualValue)	Uses the actual position of the axis specified to the input axis in the current operation cycle.

- If using "101: Latest Set Value (mcLatestSetValue)" and "102: Latest Actual Value (mcLatestActualValue)", the commands of multiple motion control FBs can be transmitted in the same operation cycle. In this case, make the first calling order and the linking order of linked motion control FBs the same.
- When Data source selection (AdvInputName.PrConst.SourceValue) is set to "1: Set Value (mcSetValue)" or "101: Latest Set Value (mcLatestSetValue)" and the master axis is disconnected or changes to servo OFF due to a servo alarm or forced stop, the change in values may become large. This can be prevented by setting Data source selection (AdvInputName.PrConst.SourceValue) to "2: Actual Value (mcActualValue)" or "102: Latest Actual Value (mcLatestActualValue)".
- When actual value is specified for an axis (virtual drive axis, virtual linked axis, virtual encoder axis) that does not have an Actual Position (AxisName.Md.ActualPosition), the axis operates by the value that is the same as Set Position (AxisName.Md.SetPosition).
- For real encoder axes, since the set position is calculated from the actual position, operation will be the same regardless of the set value.

■Smoothing time constant (AdvInputName.PrConst.SmoothingTimeConstant)



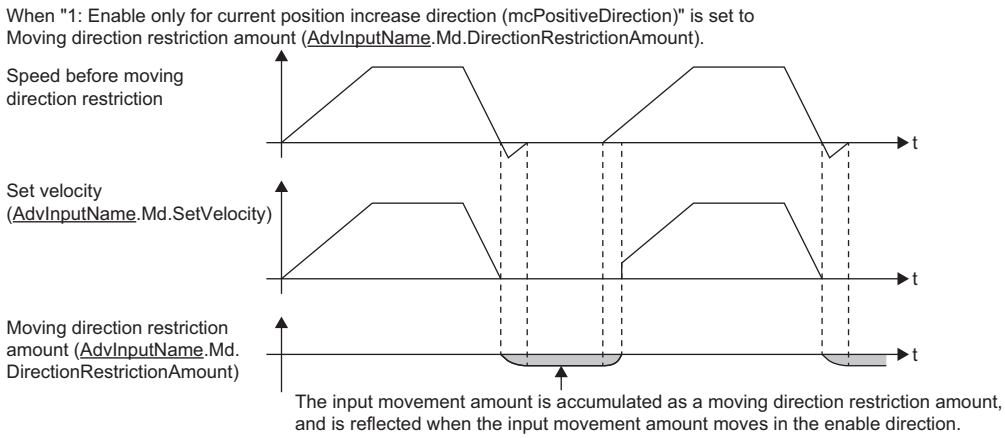
Set the averaged time for the smoothing process of the input movement amount from the input axis. The smoothing process can moderate velocity change when "Actual Value" or "Latest Actual Value" is set to the input value. However, the input response is delayed by the set time due to the smoothing process.

■Phase compensation time constant (AdvInputName.PrConst.PhaseCompensationTimeConstant)

Set the time constant for reflecting the phase compensation amount for the first order delay.

63% of the phase compensation amount is reflected in the specified time constant.

■Moving direction restriction (AdvInputName.PrConst.DirectionRestriction)



Set this parameter to restrict the input movement amount from the input axis to one direction.

Setting value	Description
0: Without movement direction restriction (NoDirectionRestriction)	Moving direction restriction is not executed.
1: Enable only for current position increase direction (mcPositiveDirection)	Enable only the input movement amount in a positive direction of the input axis cumulative current position.
2: Enable only for current position decrease direction (mcNegativeDirection)	Enable only the input movement amount in a negative direction of the input axis cumulative current position.

The input movement amounts of the enable direction and opposite direction are accumulated as a moving direction restriction amount, which will be reflected when the input movement amount is in the enable direction. As such, even when reverse operations are repeated, there will be no deviation in the input axis cumulative current position.

When the following operations are conducted for the input axis, the movement amount will be cleared to 0.

- When a servo amplifier is connected
- When a servo amplifier is disconnected
- When homing is executed
- When the current position is changed

Input axis parameter (AdvInputName.Pr.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
PhaseCompensationAdvanceTime	Phase compensation advance time	Operation cycle	DINT	-100000000 to 100000000 [μs]	0

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Phase compensation advance time (AdvInputName.Pr.PhaseCompensationAdvanceTime)

Sets the time to advance or delay the phase (input response) of the input axis.

Setting value	Description
1 to 100000000 [μs]	Advance the phase (input response) according to the setting time.
0 [μs]	Do not execute phase compensation.
-100000000 to 1 [μs]	Delay the phase (input response) according to the setting time.

If the setting time is too long, the system experiences overshoot or undershoot at acceleration/deceleration of the input speed. In this case, set longer time to reflect the phase compensation amount in Phase compensation time constant (AdvInputName.PrConst.PhaseCompensationTimeConstant).

Input axis monitor data (AdvInputName.Md.)

Variable name	Name	Import*1	Data type*1	Stored value
ActiveStatus	Active status	Immediate	INT	• -1: Disabled • 0: Not connected • 1: Input axis enabled
CumulativePosition	Cumulative current position	Operation cycle	LREAL	-10000000000.0 ≤ Input axis cumulative current position < 10000000000.0 [Position command unit of the axis set as the input axis]
SetVelocity	Set velocity		LREAL	-2500000000.0 to 2500000000.0 [Position command unit of the axis set as the input axis]
PhaseCompensationAmount	Phase compensation amount		LREAL	-2147483648.0 to 2147483647.0 [Position command unit of the axis set as the input axis]
DirectionRestrictionAmount	Moving direction restriction amount		LREAL	-2147483648.0 to 2147483647.0 [Position command unit of the axis set as the input axis]

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Active status (AdvInputName.Md.ActiveStatus)

Stores the status of the input axis.

Setting value	Description
-1: Disabled	Input axis generation has failed due to parameters being outside the possible range.
0: Not connected	The initial processing of the axis set as an input axis has not been completed, such as when a servo amplifier is not connected.
1: Input axis enabled	The input axis can be used for synchronous control.

■Cumulative current position (AdvInputName.Md.CumulativePosition)

The cumulative current position of the input axis is stored in the position units of the axis set in the input axis Axis information (AdvInputName.Axis) as shown below.

The current position of the input axis is the value after smoothing, phase compensation, and movement direction restriction processes.

Data source selection (AdvInputName.PrConst.SourceValue) setting value	Description
1: Set Value (mcSetValue)	• The set position of the axis set in the input axis Axis information (AdvInputName.Axis) in the previous operation cycle is stored. • When the set current position or the actual current position is changed by homing or current position change, it will be changed to the current position after change.
2: Actual Value (mcActualValue)	The value calculated using the position address returned by the device station of the axis set in the input axis Axis information (AdvInputName.Axis) in the previous operation cycle is stored.
101: Latest Set Value (mcLatestSetValue)	• The set position of the axis set in the input axis Axis information (AdvInputName.Axis) in this operation cycle is stored. • When the set current position or the actual current position is changed by homing or current position change, it will be changed to the current position after change.
102: Latest Actual Value (mcLatestActualValue)	The value calculated using the position address returned by the device station of the axis set in the input axis Axis information (AdvInputName.Axis) in this operation cycle is stored.

■Set velocity (AdvInputName.Md.SetVelocity)

The speed of the input axis is stored in speed units of the axis set in the input axis Axis information (AdvInputName.Axis).

The speed of the input axis is the value after smoothing, phase compensation, and moving direction restriction processes.

Point

Depending on the movement amount per input axis operation cycle, the range of "-2500000000.0 to 2500000000.0" may be exceeded.

■Phase compensation amount (AdvInputName.Md.PhaseCompensationAmount)

The phase compensation amount of the input axis is stored in position command units of the axis set in the input axis Axis information (AdvInputName.Axis).

The phase compensation amount of the input axis is the value after smoothing and phase compensation processes.

■Moving direction restriction amount (AdvInputName.Md.DirectionRestrictionAmount)

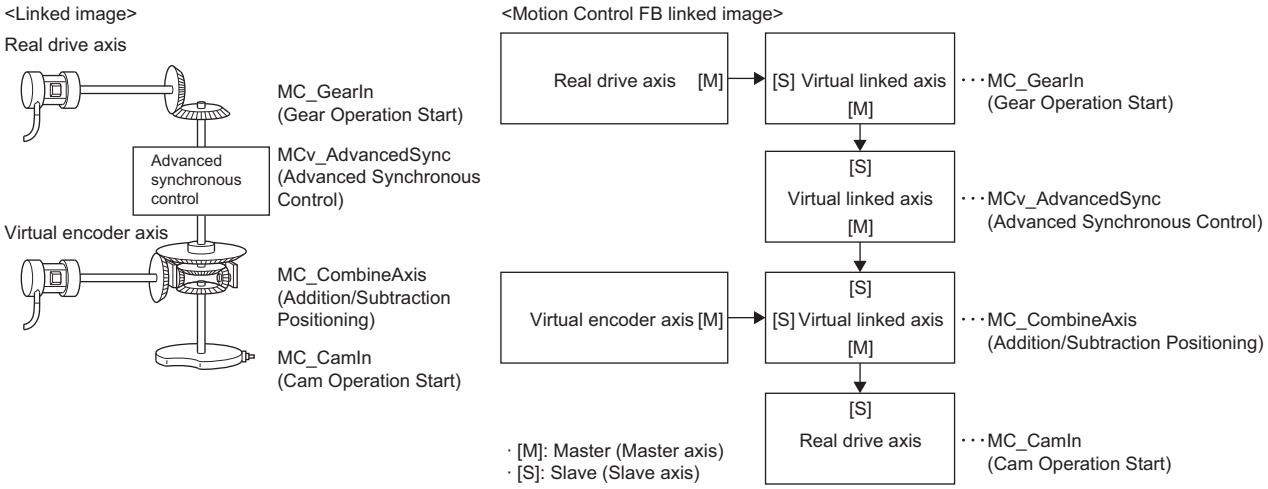
During moving direction restriction of the input axis, the enabled direction and the cumulative value of the opposite input movement amount are stored as shown below in position units of the axis specified as the input axis.

Moving direction restriction (AdvInputName.PrConst.DirectionRestriction) setting value	Description
1: Enable only for current position increase direction	A negative cumulative value is stored during moving direction restriction. "0.0" is stored if there is no restriction.
2: Enable only for current position decrease direction	Stores positive cumulative values during moving direction restriction. "0.0" is stored if there is no restriction.

Since the moving direction restriction is processed after the phase compensation process, if an undershoot occurs due to phase compensation during a deceleration stop, the moving direction restriction amount may remain.

Precautions

The following are precautions for using an input axis.



Advanced synchronous control operation overflow warning

When the driver conversion numerator/driver conversion denominator setting value of the axis set in the input axis Axis information (AdvInputName.Axis) or the input axis speed is significantly large, an overflow in the internal operation of the input axis will occur, and Advanced Synchronous Control Operation Overflow Warning (event code: 00D3EH) may occur. When a warning occurs, the synchronized position of the input axis and output axis may shift out of position. In this case, fix the setting values of the driver conversion numerator/driver conversion denominator or reduce the speed of the input axis.

Advanced synchronous control linking order

The Latest Set Value (mcLatestSetValue) and Latest Actual Value (mcLatestActualValue) of the Data Source Selection (AdvInputName.PrConst.SourceValue) use a position of the master axis in the same operation cycle, and the others use a position of the master axis in the previous operation cycle.
Using the Latest Set Value (mcLatestSetValue) and Latest Actual Value (mcLatestActualValue) can transmit multiple motion control FB commands in the same operation cycle. In this case, make the first calling order and the linking order of linked motion control FBs the same.

Ex.
When transmitting movement of the real drive axis, the virtual encoder axis, and advanced synchronous control to MC_CamIn (Cam Operation Start) control in the same operation cycle

When using the above combination of MCv_AdvancedSync (Advanced Synchronous Control) and single axis synchronous control FB (linked order), set the first call order as follows.

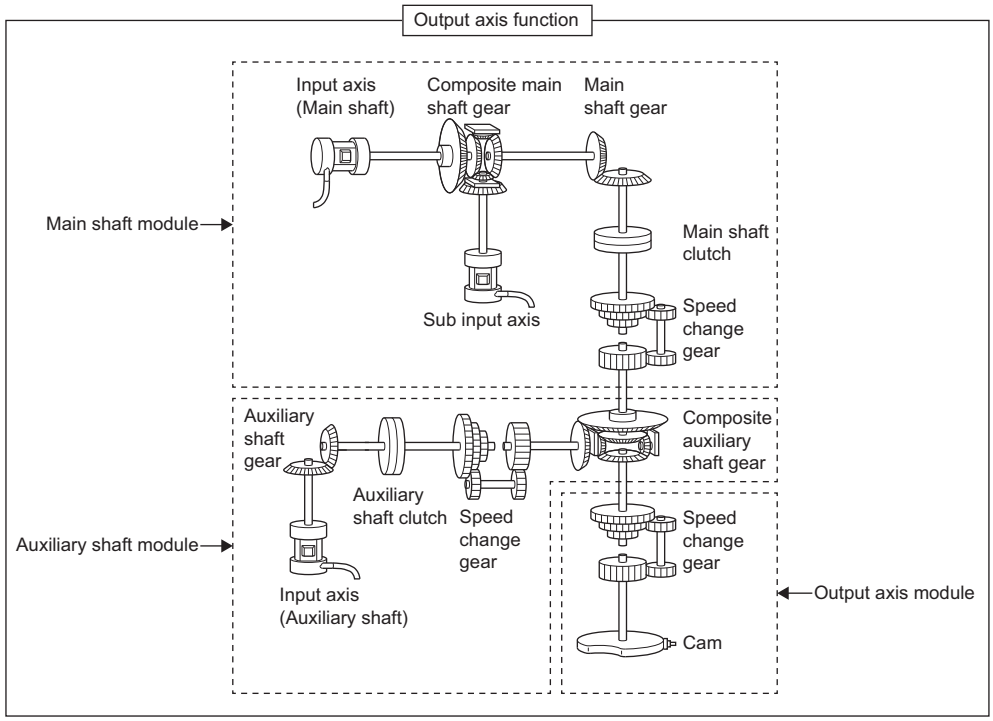
- First call order

1. Motion control FB which moves the real drive axis set as a Master axis (Master) of MC_GearIn (Gear Operation Start)
2. MC_GearIn (Gear Operation Start)
3. MCv_AdvancedSync (Advanced Synchronous Control)
4. MC_CombineAxes (Addition/Subtraction Positioning)
5. MC_CamIn (Cam Operation Start)

- Set Master axis data source selection (MasterValueSource) of each single axis synchronous control FB and advanced synchronous control data source selection (AdvInputName.PConst.PosSource) to "101: Latest Set Value (mcLatestSetValue)".

33.4 Output Axis Function

In GX Works3, configure output settings and generate and initialize the output axes necessary for advanced synchronous control.



Output axes are defined as the output axis variables consisting of parameter information, control data, and monitor information such as current positions.

Any generated output axes are specified in the output axis Axis information (AdvOutputName.Axis) of the Slave Axis (Slave) of MCv_AdvancedSync (Advanced Synchronous Control).

When a warning or error occurs on the output axis, the warning or error is stored in the axis set in the output axis Axis information (AdvOutputName.Axis).

This section describes the parameters, control data, and monitor data of the "Main shaft module", "Auxiliary shaft module", and "Output axis module" of advanced synchronous control.

The "Main shaft module", "Auxiliary shaft module" and "Output axis module" are defined as shown below.

Point

The arrangement and number of modules in advanced synchronous control are fixed.

Output axis initialization timing

The output axis variables are initialized at the following timings.

Timing	Processing
• Power ON • Reset	Refers to the global label data, and initializes all set output axis variables.
At PLC READY OFF → ON	■Uninitialized axes Refers to the global label data and initializes all output axis variables. ■Initialized axes Refer to the global label data for the output axis parameter data (AdvOutputName.Pr.□) and reload again. When the parameter error occurs at loading, the axis is not deleted. In this case, the READY does not turn on. For the label initialization processing when the PLC READY turns off to on, refer to "Label initialization function" in the following manual. 📖MELSEC MX Controller MX-R Model Programming Manual

Output axis positioning range

- Set the Ring counter lower limit value (AxisName.PrConst.RingCount_LowerValue) and Ring counter upper limit value (AxisName.PrConst.RingCount_UpperValue) to the values below. If any other values are set, an Out of Advanced Synchronous Control Output Axis Ring Counter Range (error code: 1B26H) error will occur at system start.

Setting range	
Ring counter lower limit value (AxisName.PrConst.RingCount_LowerValue)	**Ring counter upper limit value (AxisName.PrConst.RingCount_UpperValue)**
0.0	0.0 < Setting value ≤ 2147483647.0
-10000000000.0	10000000000.0

- Do not set digits after the decimal point in the Ring counter lower limit value (AxisName.PrConst.RingCount_LowerValue) and Ring counter upper limit value (AxisName.PrConst.RingCount_UpperValue) of the positioning range of the axis set in the output axis Axis information (AdvOutputName.Axis). If set, an error will occur with the value output to the slave axis and the Set position (AxisName.Md.SetPosition) of the axis set to the output axis in synchronous control when the permissible value is exceeded.

Output axis relevant variables

Output axis (AdvOutputName.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
LabelID	Axis label ID	At system start	WORD (UINT)	1 to 256	0
Axis	Axis information		AXIS_REF	—	—

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Axis label ID (AdvOutputName.LabelID)

- Sets the label ID of the output axis.
- The range is 1 to 256.

■Axis information (AdvOutputName.Axis)

- Sets the Axis information (AxisName.AxisRef) of the axis that will be the output axis for advanced synchronous control.
- Up to 256 output axes can be generated.
- It is not possible to set the same axis to the axis information of different output axes.
- Do not set the Axis information of an axis (AxisName.AxisRef) defined in local labels. If it is set, output axes will not be generated.
- Settable axis types to the output axis are shown below.

○: Can be set, ×: Cannot be set

Axis type		Output axis setting
Real axis	Real drive axis	○
	Real encoder axis	×*1
Virtual axis	Virtual drive axis	○
	Virtual encoder axis	×*1
	Virtual linked axis	○

*1 If set, Advanced Synchronous Control Output Axis Incorrect (error code: 1A0FH) will occur.

Output axis parameter constant (AdvOutputName.PrConst.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
SmoothingTimeConstant	Output axis smoothing time constant	At system start	WORD (UINT)	0 to 5000 [ms]	0 [ms]

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Output axis smoothing time constant (AdvOutputName.PrConst.SmoothingTimeConstant)

Set the averaging time to execute a smoothing process for the movement amount to the output axis after cam conversion.
The smoothing process can moderate rapid velocity changes on the cam of cam data (linear interpolation) or others.
However, the output response is delayed by the set time due to the smoothing process.

Output axis parameter (AdvOutputName.Pr.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
SubAxis	Sub input axis object	At start	AXIS_REF	—	—
AuxAxis	Auxiliary axis object		AXIS_REF	—	—

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Sub input axis object (AdvOutputName.Pr.SubAxis)

Set the sub input axis object axis.

This variable will be disabled when set to "0".

When an axis to which input settings have not been assigned is set, Advanced Synchronization Control Axis Unset (error code: 1B22H) will occur.

■Auxiliary shaft object (AdvOutputName.Pr.AuxAxis)

Set the auxiliary axis object axis.

This variable will be disabled when set to "0".

When an axis to which input settings have not been assigned is set, Advanced Synchronization Control Axis Unset (error code: 1B22H) will occur.

Output axis monitor data (AdvOutputName.Md.)

Variable name	Name	Import*1	Data type*1	Stored value
Synchronous status	SyncStatus	At start	INT	• -1: Disabled • 0: Not synchronizing • 1: In synchronization
Master shaft	MasterAxisNo		WORD (UINT)	0 to 10000
Sub input axis	SubAxisNo		WORD (UINT)	0 to 10000
Auxiliary axis	AuxAxisNo		WORD (UINT)	0 to 10000

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Synchronization status (AdvOutputName.Md.SyncStatus)

The synchronization status of the output axis is stored.

Setting value	Description
-1: Disabled	The output axis cannot be used in this status due to being in initial processing or because of out of range parameters.
0: Not synchronizing	The output axis is not synchronized with the input axis by MCv_AdvancedSync (Advanced Synchronous Control).
1: In synchronization	The output axis is synchronized with the input axis by MCv_AdvancedSync (Advanced Synchronous Control).

■Main shaft (AdvOutputName.Md.MasterAxisNo)

The axis number of the main shaft set in the input axis Axis information (AdvInputName.Axis) in synchronization with the output axis is stored.

"0" is stored when a main shaft is not connected.

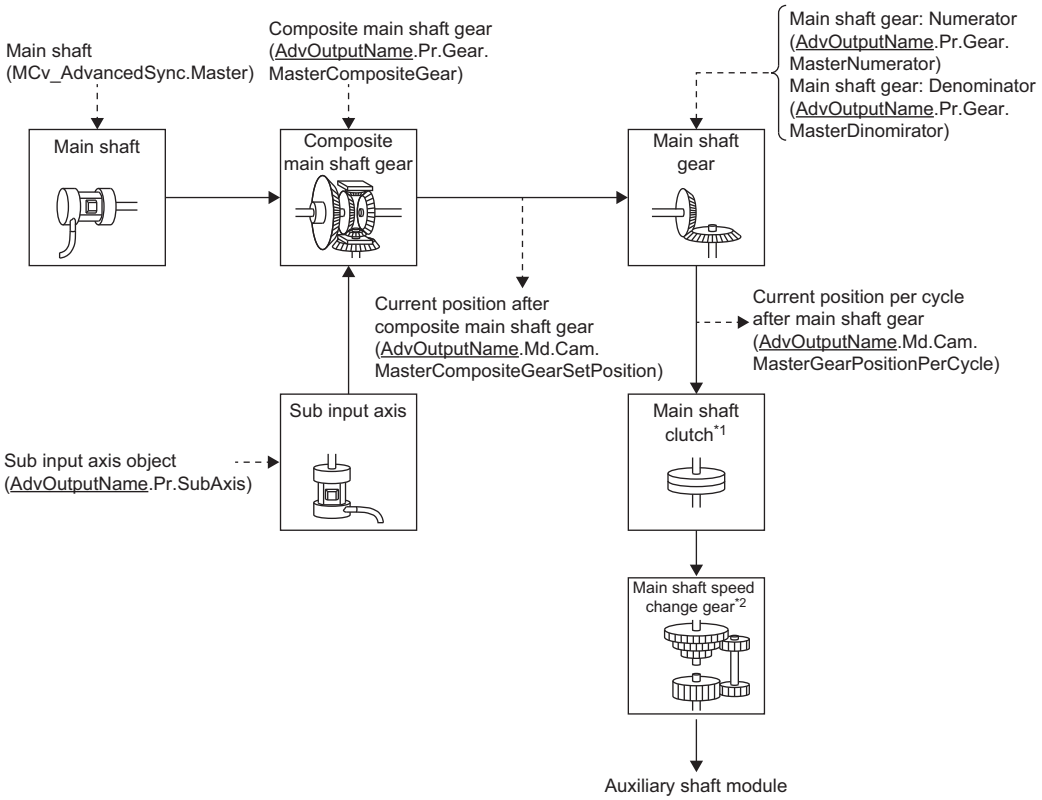
■Sub input axis (AdvOutputName.Md.SubAxisNo)

The axis number of the sub input axis set in the input axis Axis information (AdvInputName.Axis) in synchronization with the output axis is stored.

"0" is stored when a sub input axis is not connected.

■Auxiliary shaft (AdvOutputName.Md.AuxAxisNo)

The axis number of the auxiliary shaft set in the input axis Axis information (AdvInputName.Axis) in synchronization with the output axis is stored.



"0" is stored when an auxiliary shaft is not connected.

Main shaft module

The main shaft control modules transmit the movement amount input from an input axis to the output axis.
The main shaft module corresponds to the axis set as the Master axis (Master) of MCv_AdvancedSync (Advanced Synchronous Control).
The functions for a main shaft control module include gears, clutches, and speed change gears. For the setting items, refer to the following.

Function	Member	Variable	Reference
Gear	Output axis parameter (AdvOutputName.Pr.)	Gear parameter (Gear.)	Page 925 Gear parameter of output axis parameters (AdvOutputName.Pr.Gear.)
Clutch	Output axis parameter constant (AdvOutputName.PrConst.)	—	Page 926 Output axis parameter constant (AdvOutputName.PrConst.)
	Output axis parameter (AdvOutputName.Pr.)	—	Page 926 Output axis parameter (AdvOutputName.Pr.)
		Clutch parameter (Clutch.)	Page 928 Clutch parameter of output axis parameters (AdvOutputName.Pr.Clutch.)
	Output axis monitor data (AdvOutputName.Md.)	Clutch monitor (Clutch.)	Page 933 Clutch monitor of output axis monitor data (AdvOutputName.Md.Clutch.)
	Output axis control data (AdvOutputName.Cd.)	Clutch control data (Clutch.)	Page 933 Clutch control data of output axis control data (AdvOutputName.Cd.Clutch.)
Speed change gear	Output axis parameter constant (AdvOutputName.PrConst.)	—	Page 962 Output axis parameter constant (AdvOutputName.PrConst.)
	Speed change gear parameter of output axis (AdvOutputName.Pr.SpeedChangeGear.)	Speed change gear parameter (SpeedChangeGear.)	Page 961 Speed change gear parameter of output axis (AdvOutputName.Pr.SpeedChangeGear.)
	Speed change gear control data of output axis (AdvOutputName.Cd.SpeedChangeGear.)	Speed change gear control data (SpeedChangeGear.)	Page 963 Speed change gear control data of output axis (AdvOutputName.Cd.SpeedChangeGear.)

- Main shaft module: The input value is generated as a composite value from two input axes (the main shaft and sub input axis) through the composite main shaft gear. The composite input value can be converted by the main shaft gear that provides the deceleration ratio, rotation direction, and other elements for the machine system.

*1 Clutch (☞ Page 947 Clutch)
*2 Speed change gear (☞ Page 960 Speed change gear)

Gear parameter of output axis parameters (AdvOutputName.Pr.Gear.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
MasterCompositeGear	Composite main shaft gear	Operation cycle (FB is starting)	WORD (HEX)	H□□□□ Main shaft input method 0: No input 1: Input + 2: Input - Sub input method 0: No input 1: Input + 2: Input -	0001H
MasterNumerator	Main shaft gear: Numerator	At start	DINT	-2147483647 to 2147483647	1
MasterDenominator	Main shaft gear: Denominator		DWORD (UDINT)	1 to 2147483647	1

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Composite main shaft gear (AdvOutputName.Pr.Gear.MasterCompositeGear)

Set the composite method for the current positions from the main shaft and sub input axis.

Setting value	Description
0: No input	The input value from the input axis is calculated as 0.
1: Input +	The input value from the input axis is calculated as it is.
2: Input -	The input value from the input axis is calculated with its opposite sign.

Operation assumes "0: No input" if the value is set out of the range from 0 to 2.

Point

The composite method for the composite main shaft gear can be changed during synchronous control. It can also be used as a clutch to switch input values of the main shaft and auxiliary shafts.

■Main shaft gear: Numerator (AdvOutputName.Pr.Gear.MasterNumerator)

Set the numerator for the main shaft gear input value conversion.

The input value is converted as follows.

$$\text{Input value after conversion} = \text{Input value before conversion} \times \frac{\text{Main shaft gear: Numerator}}{\text{Main shaft gear: Denominator}}$$

The input value direction can be reversed by setting a negative value in the setting value of the gear numerator.

Point

Set a reduced fraction for "Main shaft gear: Numerator/Main shaft gear: Denominator".

■Main shaft gear: Denominator (AdvOutputName.Pr.Gear.MasterDenominator)

Set the denominator for the main shaft gear input value conversion.

Set together with Main shaft gear: Numerator.

Output axis parameter constant (AdvOutputName.PrConst.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
MasterClutchSmoothingTimeConstant	Main shaft clutch smoothing time constant	At system start	WORD (UINT)	0 to 5000 [ms]	0 [ms]

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Main shaft clutch smoothing time constant (AdvOutputName.PrConst.MasterClutchSmoothingTimeConstant)

Set a time constant when the time constant method is set to "1: Time constant method (Exponent) (TimeConstantExponent)" or "2: Time constant method (Linear) (TimeConstantLinear)" in the Main shaft clutch smoothing method (AdvOutputName.Pr.Clutch.MasterSmoothingMethod).
The time constant setting applies for both clutch ON/OFF.

Output axis parameter (AdvOutputName.Pr.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
MasterOnClutchSignal	Main shaft clutch ON signal setting	At system start	SIGNAL_SELECT	—	—
MasterOffClutchSignal	Main shaft clutch OFF signal setting			—	—

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Main shaft clutch ON signal setting (AdvOutputName.Pr.MasterOnClutchSignal)

Set the variable and device used as the clutch external signal in SIGNAL_SELECT structure when the Main shaft clutch ON control setting (AdvOutputName.Pr.Clutch.MasterOnControl) is set to "15: I/O data specification (ClutchSignal)". For SIGNAL_SELECT structure, refer to the following.
☞ Page 1156 SIGNAL_SELECT Structure
The following shows the settings peculiar to Main shaft clutch ON signal setting (AdvOutputName.Pr.MasterOnClutchSignal).

Structure	Variable name	Type	Setting range
SIGNAL_SELECT (Signal Select)	Source (Signal)	TARGET_REF	■Type • BOOL ■Data type • [OBJ] • [VAR] • [DEV] • [LINK]
	Detection (Signal detection method)	INT (MC_SIGNAL_LOGIC)	• 2: Detection at FALSE → TRUE (Rising edge) (RisingEdge) • 3: Detection at TRUE → FALSE (Falling edge) (FallingEdge) • 4: Detection at rising edge/falling edge (BothEdges)
	CompensationTime (Compensation time)	LREAL	-5.0 to 5.0 [s]
	FilterTime (Filter time)	LREAL	0.0 [s]

Point

If the following data types are set to the target (Source.Target), after communication with the device station has been established, start MCv_AdvancedSync (Advanced Synchronous Control). If the communication has not been established, External Signal Selection Incorrect (error code: 1BD6H) (detail code: 0002H) occurs.
• [OBJ]
• [LINK]

■Main shaft clutch OFF signal setting (AdvOutputName.Pr.MasterOffClutchSignal)

Set the variable and device used as the clutch external signal in SIGNAL_SELECT structure when the Main shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.MasterOffControl) is set to "15: I/O data specification (ClutchSignal)". For SIGNAL_SELECT structure, refer to the following.

☞ Page 1156 SIGNAL_SELECT Structure

The following shows the settings peculiar to Main shaft clutch OFF signal setting (AdvOutputName.Pr.MasterOffClutchSignal).

Structure	Variable name	Type	Setting range
SIGNAL_SELECT (Signal Select)	Source (Signal)	TARGET_REF	■Type • BOOL ■Data type • [OBJ] • [VAR] • [DEV] • [LINK]
	Detection (Signal detection method)	INT (MC_SIGNAL_LOGIC)	• 2: Detection at FALSE → TRUE (Rising edge) (RisingEdge) • 3: Detection at TRUE → FALSE (Falling edge) (FallingEdge) • 4: Detection at rising edge/falling edge (BothEdges)
	CompensationTime (Compensation time)	LREAL	-5.0 to 5.0 [s]
	FilterTime (Filter time)	LREAL	0.0 [s]

Point

If the following data types are set to the target (Source.Target), after communication with the device station has been established, start MCv_AdvancedSync (Advanced Synchronous Control). If the communication has not been established, External Signal Selection Incorrect (error code: 1BD6H) (detail code: 0002H) occurs.

• [OBJ]

• [LINK]

Clutch parameter of output axis parameters (AdvOutputName.Pr.Clutch.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
MasterOnControl	Main shaft clutch ON control setting	Operation cycle (FB is starting)	INT (MC_CLUTCH_METHOD)	• 0: Invalid (NoClutch) (Direct coupled operation) • 1: Clutch command (ClutchCommand) • 2: Clutch command leading edge (ClutchLeadingEdge) • 3: Clutch command trailing edge (ClutchTrailingEdge) • 4: Address mode (ClutchAddress) • 15: I/O data specification (ClutchSignal)	0: Invalid (NoClutch)
MasterOffControl	Main shaft clutch OFF control setting		INT (MC_CLUTCH_METHOD)	• 0: Invalid (NoClutch) (OFF control invalid) • 1: Clutch command (ClutchCommand) (One-shot operation) • 2: Clutch command leading edge (ClutchLeadingEdge) • 3: Clutch command trailing edge (ClutchTrailingEdge) • 4: Address mode (ClutchAddress) • 15: I/O data specification (ClutchSignal)	0: Invalid (NoClutch)
MasterReference	Main shaft clutch reference address setting	At start	INT (MC_CLUTCH_REFERENCE)	• 0: Current position before gear (GearFrontPosition) • 1: Current position per cycle after gear (GearPositionPerCycle)	0: Current position before gear (GearFrontPosition)
MasterOnAddress	Main shaft clutch ON address	Operation cycle (FB is starting)	LREAL	-10000000000.0 to 10000000000.0	0.0
MasterMovementAmountBeforeOn	Movement amount before main shaft clutch ON	At completing clutch ON condition	LREAL	-2147483648.0 to 2147483647.0	0.0
MasterOffAddress	Main shaft clutch OFF address	Operation cycle (FB is starting)	LREAL	-10000000000.0 to 10000000000.0	0.0
MasterMovementAmountBeforeOff	Movement amount before main shaft clutch OFF	At completing clutch OFF condition	LREAL	-2147483648.0 to 2147483647.0	0.0
MasterSmoothingMethod	Main shaft clutch smoothing method	At start	INT (MC_CLUTCH_SMOOTHING_METHOD)	• 0: Direct (ClutchSmoothingDisabled) • 1: Time constant method (Exponent) (TimeConstantExponent) • 2: Time constant method (Linear) (TimeConstantLinear) • 3: Slippage method (Exponent) (SlippageExponent) • 4: Slippage method (Linear) (SlippageLinear) • 5: Slippage method (Linear: Input value follow up) (SlippageLinearFollow)	0: Direct (ClutchSmoothingDisabled)
MasterOnSlippageAmount	Slippage amount at main shaft clutch ON	At turning clutch on	LREAL	0.0 to 2147483647.0	0.0
MasterOffSlippageAmount	Slippage amount at main shaft clutch OFF	At turning clutch off	LREAL	0.0 to 2147483647.0	0.0

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Main shaft clutch ON control setting (AdvOutputName.Pr.Clutch.MasterOnControl)

Set the control method for main shaft clutch ON. The Main shaft clutch ON control setting (AdvOutputName.Pr.Clutch.MasterOnControl) can be changed during synchronous control. However, changes from settings other than "0: Invalid (NoClutch)" to "0: Invalid (NoClutch)" are not possible.

Setting value	Description
0: Invalid (NoClutch) (Direct coupled operation)	Execute direct coupled operation without clutch control.
1: Clutch command (ClutchCommand)	The clutch is turned on/off by the operations of the Main shaft clutch command (AdvOutputName.Cd.Clutch.MasterCommand) TRUE/FALSE. (In the clutch command ON/OFF mode, the setting in the Main shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.MasterOffControl) is not referred to.)
2: Clutch command leading edge (ClutchLeadingEdge)	The clutch is turned on when the Main shaft clutch command (AdvOutputName.Cd.Clutch.MasterCommand) passes the leading edge (from FALSE to TRUE).
3: Clutch command trailing edge (ClutchTrailingEdge)	The clutch is turned on when the Main shaft clutch command (AdvOutputName.Cd.Clutch.MasterCommand) passes the trailing edge (from TRUE to FALSE).
4: Address mode (ClutchAddress)	The clutch is turned on when the reference address (the current position after composite main shaft gear or the current position per cycle after main shaft gear) reaches the Main shaft clutch ON address (AdvOutputName.Pr.Clutch.MasterOnAddress). When the reference address passes through the ON address, the movement amount after the ON address is passed is output as the output movement amount of the clutch. Therefore, the clutch is controlled with the accurate movement amount.
15: I/O data specification (ClutchSignal)	The clutch is turned on when the external input signal set in the Main shaft clutch ON signal setting (AdvOutputName.Pr.MasterOnClutchSignal) is detected.

Point

- Other clutch parameter settings are not referred to because direct coupled operation is performed by setting the Main shaft clutch ON control setting (AdvOutputName.Pr.Clutch.MasterOnControl) to "0: Invalid (NoClutch)". The Main shaft clutch forced OFF command (AdvOutputName.Cd.Clutch.MasterForcedOff) and the change of the clutch control setting are ignored during direct coupled operation.
- Changes from settings other than "0: Invalid (NoClutch)" to "0: Invalid (NoClutch)" are not possible during synchronous control. If the setting is changed in that manner, Out of Advanced Synchronous Control Variable Range Warning (error code: 0D3FH) occurs.

■Main shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.MasterOffControl)

Set the control method for main shaft clutch OFF.

Setting value	Description
0: Invalid (NoClutch) (OFF control invalid)	Clutch OFF control is not used. Set it only for execution with clutch ON control.
1: Clutch command (ClutchCommand) (One-shot operation)	After Main shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.MasterOnOffStatus) is turned on, it moves the distance set in Movement amount before main shaft clutch OFF (AdvOutputName.Pr.Clutch.MasterMovementAmountBeforeOff), then the clutch turns off. (One-shot operation) If the Movement amount before main shaft clutch OFF (AdvOutputName.Pr.Clutch.MasterMovementAmountBeforeOff) is "0.0", the Main shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.MasterOnOffStatus) does not turn to "TRUE (Clutch ON status)" in order to turn back off immediately.
2: Clutch command leading edge (ClutchLeadingEdge)	The clutch is turned off when the Main shaft clutch command (AdvOutputName.Cd.Clutch.MasterCommand) passes the leading edge (from FALSE to TRUE).
3: Clutch command trailing edge (ClutchTrailingEdge)	The clutch is turned off when the Main shaft clutch command (AdvOutputName.Cd.Clutch.MasterCommand) passes the trailing edge (from TRUE to FALSE).
4: Address mode (ClutchAddress)	The clutch is turned off when the reference address (the current position after composite main shaft gear or the current position per cycle after main shaft gear) reaches the Main shaft clutch OFF address (AdvOutputName.Pr.Clutch.MasterOffAddress). When the reference address passes through the OFF address, the movement amount after the OFF address is passed is output as the output movement amount of the clutch. Therefore, the clutch is controlled with the accurate movement amount.
15: I/O data specification (ClutchSignal)	The clutch is turned off when the external input signal set in the Main shaft clutch OFF signal setting (AdvOutputName.Pr.MasterOffClutchSignal) is detected.

■Main shaft clutch reference address setting (AdvOutputName.Pr.Clutch.MasterReference)

Set the address to be referred to at clutch control.

Note that the processing order of gears and clutches varies by the reference address.

Setting value	Description
0: Current position before gear (GearFrontPosition)	The clutch is controlled by using the current position after composite main shaft gear, which is before the main shaft gear conversion. The movement amount after the clutch control is converted then output through the main shaft gear. * The clutch processing is performed for the current position after composite main shaft gear. The current position after composite main shaft gear is used as the reference address when the Main shaft clutch ON control setting (AdvOutputName.Pr.Clutch.MasterOnControl) is set to "4: Address mode (ClutchAddress)".
1: Current position per cycle after gear (GearPositionPerCycle)	The clutch is controlled by using the current position per cycle after main shaft gear. The movement amount after the main shaft clutch control is output as it is. * The clutch processing is performed for the current position per cycle after main shaft gear. The current position per cycle after main shaft gear is used as the reference address when the Main shaft clutch ON control setting (AdvOutputName.Pr.Clutch.MasterOnControl) is set to "4: Address mode (ClutchAddress)".

The unit settings of the following parameters are in position command units of the main shaft.

- Main shaft clutch ON address (AdvOutputName.Pr.Clutch.MasterOnAddress)
- Main shaft clutch OFF address (AdvOutputName.Pr.Clutch.MasterOffAddress)
- Movement amount before main shaft clutch ON (AdvOutputName.Pr.Clutch.MasterMovementAmountBeforeOn)
- Movement amount before main shaft clutch OFF (AdvOutputName.Pr.Clutch.MasterMovementAmountBeforeOff)
- Slippage amount at main shaft clutch ON (AdvOutputName.Pr.Clutch.MasterOnSlippageAmount)
- Slippage amount at main shaft clutch OFF (AdvOutputName.Pr.Clutch.MasterOffSlippageAmount)

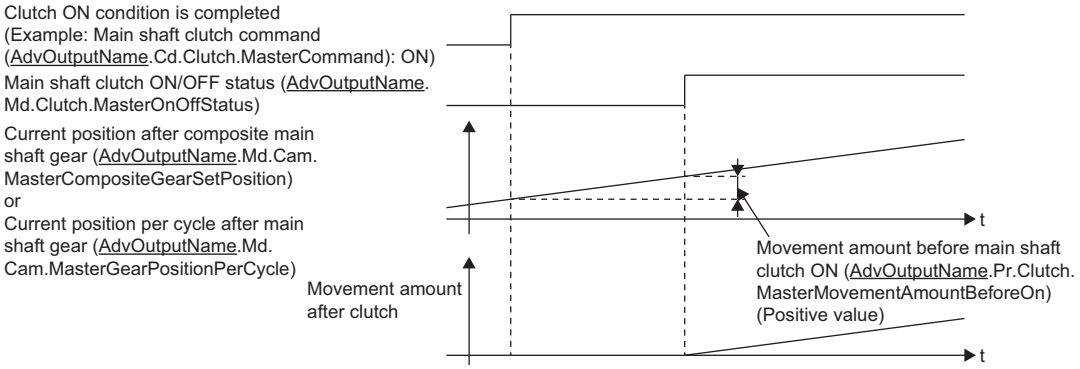
■Main shaft clutch ON address (AdvOutputName.Pr.Clutch.MasterOnAddress)

Set the clutch ON address when "4: Address mode (ClutchAddress)" is set in the Main shaft clutch ON control setting (AdvOutputName.Pr.Clutch.MasterOnControl).

When "1: Current position per cycle after gear (GearPositionPerCycle)" is set in the Main shaft clutch reference address setting (AdvOutputName.Pr.Clutch.MasterReference), the setting address is converted for control within the range from "0.0 to (length per cycle - 0.00001)".

Setting value
-10000000000.0 ≤ Main shaft clutch ON address (AdvOutputName.Pr.Clutch.MasterOnAddress) < 10000000000.0

Ex.



Length per cycle: 20000.0

The ON address is controlled as "19000.0" when the setting value is "-1000.0".

■Movement amount before main shaft clutch ON (AdvOutputName.Pr.Clutch.MasterMovementAmountBeforeOn)

Set the movement amount for the reference address with a signed number regarding from when the main shaft clutch ON condition is met until when the clutch turns on.

Setting value	Description
0.00001 to 2147483647.0 (Positive value)	Used when the reference address is increasing in direction.
0.0	No movement (The clutch turns on at the same time as when the ON condition is met.)
-2147483648.0 to -0.00001 (Negative value)	Used when the reference address is decreasing in direction.

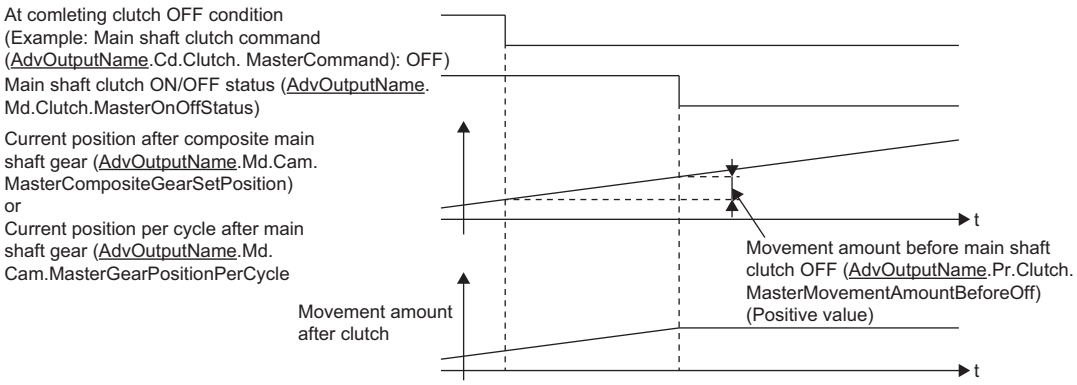
■Main shaft clutch OFF address (AdvOutputName.Pr.Clutch.MasterOffAddress)

Set the clutch OFF address when "4: Address mode (ClutchAddress)" is set in the Main shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.MasterOffControl).

When "1: Current position per cycle after gear (GearPositionPerCycle)" is set in the Main shaft clutch reference address setting (AdvOutputName.Pr.Clutch.MasterReference), the setting address is converted for control within the range from "0.0 to (length per cycle - 0.00001)".

Setting value
-10000000000.0 ≤ Main shaft clutch OFF address (AdvOutputName.Pr.Clutch.MasterOffAddress) < 10000000000.0

Ex.



Length per cycle: 20000.0

The OFF address is controlled as "60.0" when the setting value is "40060.0".

■Movement amount before main shaft clutch OFF (AdvOutputName.Pr.Clutch.MasterMovementAmountBeforeOff)

Set the movement amount for the reference address with a signed number regarding from when the main shaft clutch OFF condition is met until when the clutch turns off.

Setting value	Description
0.00001 to 2147483647.0 (Positive value)	Used when the reference address is increasing in direction.
0.0	No movement (The clutch turns off at the same time as when the OFF condition is met.)
-2147483648.0 to -0.00001 (Negative value)	Used when the reference address is decreasing in direction.

■Main shaft clutch smoothing method (AdvOutputName.Pr.Clutch.MasterSmoothingMethod)

Set the smoothing method for clutch ON/OFF.

Setting value	Description
0: Direct (ClutchSmoothingDisabled)	No smoothing for the main shaft clutch.
1: Time constant method (Exponent) (TimeConstantExponent)	Smoothing with an exponential curve based on the time constant setting.
2: Time constant method (Linear) (TimeConstantLinear)	Smoothing with linear acceleration/deceleration based on the time constant setting.
3: Slippage method (Exponent) (SlippageExponent)	Smoothing with an exponential curve based on the slippage amount setting.
4: Slippage method (Linear) (SlippageLinear)	Smoothing with linear acceleration/deceleration based on the slippage amount setting.
5: Slippage method (Linear: Input value follow up) (SlippageLinearFollow)	Smoothing with linear acceleration/deceleration (input value follow up) based on the slippage amount setting.

■Slippage amount at main shaft clutch ON (AdvOutputName.Pr.Clutch.MasterOnSlippageAmount)

Set the slippage amount at clutch ON when any of the following is set in the Main shaft clutch smoothing method (AdvOutputName.Pr.Clutch.MasterSmoothingMethod). "3: Slippage method (Exponent) (SlippageExponent)", "4: Slippage method (Linear) (SlippageLinear)", or "5: Slippage method (Linear: Input value follow up) (SlippageLinearFollow)".
The slippage amount is set in units based on the setting in the Main shaft clutch reference address setting (AdvOutputName.Pr.Clutch.MasterReference).
If the set amount is negative, slippage amount at clutch ON is controlled as 0 (direct).

Point

Do not set digits after the decimal point when "3: Slippage method (Exponent) (SlippageExponent)" is set in the Main shaft clutch smoothing method (AdvOutputName.Pr.Clutch.MasterSmoothingMethod). If set, smoothing is performed with the digits after the decimal point ignored.

■Slippage amount at main shaft clutch OFF (AdvOutputName.Pr.Clutch.MasterOffSlippageAmount)

Set the slippage amount at clutch OFF when any of the following is set in the Main shaft clutch smoothing method (AdvOutputName.Pr.Clutch.MasterSmoothingMethod). "3: Slippage method (Exponent) (SlippageExponent)", "4: Slippage method (Linear) (SlippageLinear)", or "5: Slippage method (Linear: Input value follow up) (SlippageLinearFollow)".
The slippage amount is set in units based on the setting in the Main shaft clutch reference address setting (AdvOutputName.Pr.Clutch.MasterReference).
If the set amount is negative, slippage amount at clutch OFF is controlled as 0 (direct).

Point

Do not set digits after the decimal point when "3: Slippage method (Exponent) (SlippageExponent)" is set in the Main shaft clutch smoothing method (AdvOutputName.Pr.Clutch.MasterSmoothingMethod). If set, smoothing is performed with the digits after the decimal point ignored.

Clutch monitor of output axis monitor data (AdvOutputName.Md.Clutch.)

Variable name	Name	Import*1	Data type*1	Monitor value
MasterOnOffStatus	Main shaft clutch ON/OFF status	Operation cycle (FB is starting)	BOOL	• FALSE: Clutch OFF status • TRUE: Clutch ON status
MasterSmoothingStatus	Main shaft clutch smoothing status		BOOL	• FALSE: Not on clutch smoothing • TRUE: On clutch smoothing
MasterCumulativeSlippage	Main shaft clutch slippage (accumulative)		LREAL	-2147483648.0 to 2147483647.0

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Main shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.MasterOnOffStatus)

The main shaft clutch ON/OFF status is stored.

■Main shaft clutch smoothing status (AdvOutputName.Md.Clutch.MasterSmoothingStatus)

The smoothing status of the main shaft clutch is stored.

The status is updated by the Main shaft clutch smoothing method (AdvOutputName.Pr.Clutch.MasterSmoothingMethod).

Method	Description
Time constant method	The status is always "TRUE: On clutch smoothing" during the clutch ON status. The status will be "FALSE: Not on clutch smoothing" when the clutch is turned off and smoothing is completed.
Slippage method	The status is "TRUE: On clutch smoothing" until the clutch accumulative slippage amount reaches the slippage at clutch ON when the clutch is turned on. The status will change to "FALSE: Not on clutch smoothing" when the clutch accumulative slippage amount reaches the slippage at clutch ON. The status is "TRUE: On clutch smoothing" until the clutch accumulative slippage amount reaches 0 when the clutch is turned off. The status will change to "FALSE: Not on clutch smoothing" when the clutch accumulative slippage amount reaches 0.

■Main shaft clutch slippage (accumulative) (AdvOutputName.Md.Clutch.MasterCumulativeSlippage)

The accumulative slippage amount with the slippage method during clutch smoothing is stored as a signed value.

The absolute value of the accumulative slippage increases to reach the slippage at clutch ON during clutch ON.

The absolute value of the accumulative slippage decreases to reach "0.0" during clutch OFF.

Monitoring of the accumulative slippage is used to check the smoothing progress with the slippage method.

Clutch control data of output axis control data (AdvOutputName.Cd.Clutch.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
MasterCommand	Main shaft clutch command	Operation cycle (FB is starting)	BOOL	• FALSE: Clutch command OFF • TRUE: Clutch command ON	FALSE
MasterInvalidCommand	Main shaft clutch control invalid command		BOOL	• FALSE: Clutch control valid • TRUE: Clutch control invalid	FALSE
MasterForcedOff	Main shaft clutch forced OFF command		BOOL	• FALSE: Clutch normal control • TRUE: Clutch forced OFF	FALSE
MasterClutchSmoothingTimeConstant	Main shaft clutch smoothing time constant change value	At start	INT	0 to 5000 [ms]	0

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Main shaft clutch command (AdvOutputName.Cd.Clutch.MasterCommand)

Sets ON/OFF for the main shaft clutch command.

This command is used when any of the following is set in the Main shaft clutch ON control setting (AdvOutputName.Pr.Clutch.MasterOnControl).

- 1: Clutch command (ClutchCommand)
- 2: Clutch command leading edge (ClutchLeadingEdge)
- 3: Clutch command trailing edge (ClutchTrailingEdge)

The status just before synchronous control starts is considered as clutch command OFF. If synchronous control is started while the clutch command is on, the condition is established just after starting synchronous control, by setting "2: Clutch command leading edge (ClutchLeadingEdge)". The condition is not established just after starting synchronous control, by setting "3: Clutch command trailing edge (ClutchTrailingEdge)".

■Main shaft clutch control invalid command (AdvOutputName.Cd.Clutch.MasterInvalidCommand)

The main shaft clutch control is invalid if "TRUE: Clutch control invalid" is set. The clutch ON/OFF status maintained is the one before clutch control becomes invalid.

Clutch control will not become invalid during movement before clutch ON and during movement before clutch OFF. Instead, clutch control will become invalid after movement is completed.

■Main shaft clutch forced OFF command (AdvOutputName.Cd.Clutch.MasterForcedOff)

Set "TRUE: Clutch forced OFF" to force the clutch OFF.

The output value from the clutch becomes "0" immediately, even during clutch smoothing. The slippage (accumulative) amount is set to 0 if smoothing with a slippage method.

Reset to "FALSE: Clutch normal control" to restart the clutch control from the clutch OFF status after using the clutch forced OFF command.

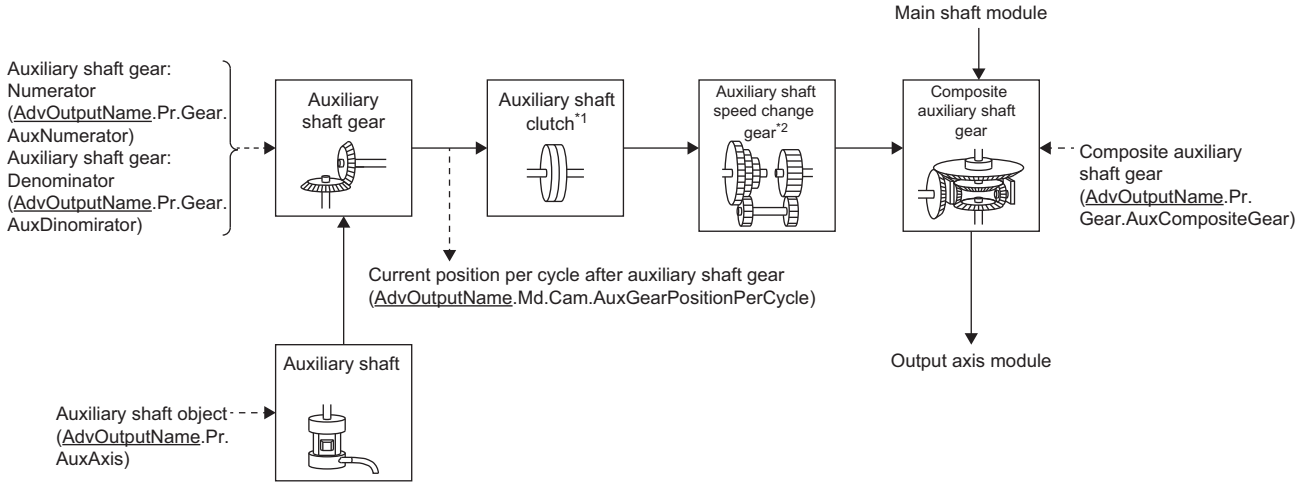
■Main shaft clutch smoothing time constant change value (AdvOutputName.Cd.Clutch.MasterClutchSmoothingTimeConstant)

The smoothing time constant of the main shaft clutch is changed. The setting is imported when MCv_AdvancedSync(Advanced Synchronous Control) is started.

Setting value	Description
When a negative value is set	No smoothing.
When 0 is set	Smoothing based on the setting value of the Main shaft clutch smoothing time constant (AdvOutputName.PrConst.MasterClutchSmoothingTimeConstant).
When a positive value is set	Smoothing based on the setting value of the Main shaft clutch smoothing time constant change value (AdvOutputName.Cd.Clutch.MasterClutchSmoothingTimeConstant).

Set within the following setting range.

If the set value exceeds the range below, "Out of Advanced Synchronous Control Variable Range Warning (error code: 0D3FH)" occurs, and smoothing is executed based on the setting value of the Main shaft clutch smoothing time constant (AdvOutputName.PrConst.MasterClutchSmoothingTimeConstant).



Setting range
Main shaft clutch smoothing time constant (AdvOutputName.PrConst.MasterClutchSmoothingTimeConstant) > Main shaft clutch smoothing time constant change value (AdvOutputName.Cd.Clutch.MasterClutchSmoothingTimeConstant)

Auxiliary shaft module

The auxiliary shaft modules transmit the movement amount input from an input axis to the output axis.
The auxiliary shaft module corresponds to the axis set in Auxiliary shaft object (AdvOutputName.Pr.AuxAxis).
The functions for an auxiliary shaft module include gears, clutches, and speed change gears. For the setting items, refer to the following.

Function	Member	Variable	Reference
Gear	Output axis parameter (AdvOutputName.Pr.)	Gear parameter (Gear.)	Page 936 Gear parameter of output axis parameters (AdvOutputName.Pr.Gear.)
Clutch	Output axis parameter constant (AdvOutputName.PrConst.)	—	Page 937 Output axis parameter constant (AdvOutputName.PrConst.)
	Output axis parameter (AdvOutputName.Pr.)	—	Page 937 Output axis parameter (AdvOutputName.Pr.)
		Clutch parameter (Clutch.)	Page 939 Clutch parameter of output axis parameters (AdvOutputName.Pr.Clutch.)
	Output axis monitor data (AdvOutputName.Md.)	Clutch monitor (Clutch.)	Page 944 Clutch monitor of output axis monitor data (AdvOutputName.Md.Clutch.)
	Output axis control data (AdvOutputName.Cd.)	Clutch control data (Clutch.)	Page 945 Clutch control data of output axis control data (AdvOutputName.Cd.Clutch.)
Speed change gear	Output axis parameter constant (AdvOutputName.PrConst.)	—	Page 962 Output axis parameter constant (AdvOutputName.PrConst.)
	Speed change gear parameter of output axis (AdvOutputName.Pr.SpeedChangeGear.)	Speed change gear parameter (SpeedChangeGear.)	Page 961 Speed change gear parameter of output axis (AdvOutputName.Pr.SpeedChangeGear.)
	Speed change gear control data of output axis (AdvOutputName.Cd.SpeedChangeGear.)	Speed change gear control data (SpeedChangeGear.)	Page 963 Speed change gear control data of output axis (AdvOutputName.Cd.SpeedChangeGear.)

- Auxiliary shaft module The input value is generated from the auxiliary shaft. The input value can be converted by the auxiliary shaft gear that provides the deceleration ratio, rotation direction, and other elements for the machine system.

*1 Clutch (☞ Page 947 Clutch)
*2 Speed change gear (☞ Page 960 Speed change gear)

Gear parameter of output axis parameters (AdvOutputName.Pr.Gear.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
AuxCompositeGear	Composite auxiliary shaft gear	Operation cycle (FB is starting)	WORD (HEX)	H□□□□ Main shaft input method 0: No input 1: Input + 2: Input - Auxiliary shaft input method 0: No input 1: Input + 2: Input -	0001H
AuxNumerator	Auxiliary shaft gear: Numerator	At start	DINT	-2147483647 to 2147483647	1
AuxDenominator	Auxiliary shaft gear: Denominator		DWORD (UDINT)	1 to 2147483647	1

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Composite auxiliary shaft gear (AdvOutputName.Pr.Gear.MasterCompositeGear)

Set the composite method for the current position after the main shaft and sub input axis composition and the current position of the auxiliary shaft.

Setting value	Description
0: No input	The input value from the input axis is calculated as 0.
1: Input +	The input value from the input axis is calculated as it is.
2: Input -	The input value from the input axis is calculated with its opposite sign.

Operation assumes "0: No input" if the value is set out of the range from 0 to 2.

Point

The composite method for the composite auxiliary shaft gear can be changed during synchronous control. It can also be used as a clutch to switch input values of the main shaft and auxiliary shafts.

■Auxiliary shaft gear: Numerator (AdvOutputName.Pr.Gear.AuxNumerator)

Set the numerator for the auxiliary gear input value conversion.

The input value is converted as follows.

$$\text{Input value after conversion} = \text{Input value before conversion} \times \frac{\text{Auxiliary shaft gear: Numerator}}{\text{Auxiliary shaft gear: Denominator}}$$

The input value direction can be reversed by setting a negative value in the setting value of the gear numerator.

Point

Set a reduced fraction for "Auxiliary shaft gear: Numerator/Auxiliary shaft gear: Denominator".

■Auxiliary shaft gear: Denominator (AdvOutputName.Pr.Gear.AuxDenominator)

Set the denominator for the auxiliary gear input value conversion.

Set together with Auxiliary gear: Numerator.

Output axis parameter constant (AdvOutputName.PrConst.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
AuxClutchSmoothingTimeConstant	Auxiliary shaft clutch smoothing time constant	At system start	WORD (UINT)	0 to 5000 [ms]	0 [ms]

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Auxiliary shaft clutch smoothing time constant (AdvOutputName.PrConst.AuxClutchSmoothingTimeConstant)

Set a time constant when the time constant method is set to "1: Time constant method (Exponent) (TimeConstantExponent)" or "2: Time constant method (Linear) (TimeConstantLinear)" in the Auxiliary shaft clutch smoothing method (AdvOutputName.Pr.Clutch.AuxSmoothingMethod).
The time constant setting applies for both clutch ON/ OFF.

Output axis parameter (AdvOutputName.Pr.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
AuxOnClutchSignal	Auxiliary shaft clutch ON signal setting	At system start	SIGNAL_SELECT	—	—
AuxOffClutchSignal	Auxiliary shaft clutch OFF signal setting			—	—

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Auxiliary shaft clutch ON signal setting (AdvOutputName.Pr.AuxOnClutchSignal)

Set the variable and device used as the clutch external signal in SIGNAL_SELECT structure when the Auxiliary shaft clutch ON control setting (AdvOutputName.Pr.Clutch.AuxOnControl) is set to "15: I/O data specification (ClutchSignal)". For SIGNAL_SELECT structure, refer to the following.
Page 1156 SIGNAL_SELECT Structure
The following shows the settings peculiar to Auxiliary shaft clutch ON signal setting (AdvOutputName.Pr.AuxOnClutchSignal).

Structure	Variable name	Type	Setting range
SIGNAL_SELECT (Signal Select)	Source (Signal)	TARGET_REF	■Type • BOOL ■Data type • [OBJ] • [VAR] • [DEV] • [LINK]
	Detection (Signal detection method)	INT (MC_SIGNAL_LOGIC)	• 2: Detection at FALSE → TRUE (rising edge) (RisingEdge) • 3: Detection at TRUE → FALSE (falling edge) (FallingEdge) • 4: Detection at rising edge/falling edge (BothEdges)
	CompensationTime (Compensation time)	LREAL	-5.0 to 5.0 [s]
	FilterTime (Filter time)	LREAL	0.0 [s]

Point

When setting [OBJ] for Target (Source.Target), start MCv_AdvancedSync (Advanced Synchronous Control) after the communication with device stations is established. If the communication is not established, External Signal Selection Incorrect (error code: 0032H) occurs.

■Auxiliary shaft clutch OFF signal setting (AdvOutputName.Pr.AuxOffClutchSignal)

Set the variable and device used as the clutch external signal in SIGNAL_SELECT structure when the Auxiliary shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.AuxOffControl) is set to "15: I/O data specification (ClutchSignal)". For SIGNAL_SELECT structure, refer to the following.

☞ Page 1156 SIGNAL_SELECT Structure

The following shows the settings peculiar to Auxiliary shaft clutch OFF signal setting (AdvOutputName.Pr.AuxOffClutchSignal).

Structure	Variable name	Type	Setting range
SIGNAL_SELECT (Signal Select)	Source (Signal)	TARGET_REF	■Type • BOOL ■Data type • [OBJ] • [VAR] • [DEV] • [LINK]
	Detection (Signal detection method)	INT (MC_SIGNAL_LOGIC)	• 2: Detection at FALSE → TRUE (rising edge) (RisingEdge) • 3: Detection at TRUE → FALSE (falling edge) (FallingEdge) • 4: Detection at rising edge/falling edge (BothEdges)
	CompensationTime (Compensation time)	LREAL	-5.0 to 5.0 [s]
	FilterTime (Filter time)	LREAL	0.0 [s]

Point

When setting [OBJ] for Target (Source.Target), start MCv_AdvancedSync (Advanced Synchronous Control) after the communication with device stations is established. If the communication is not established, External Signal Selection Incorrect (error code: 0032H) occurs.

Clutch parameter of output axis parameters (AdvOutputName.Pr.Clutch.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
AuxOnControl	Auxiliary shaft clutch ON control setting	Operation cycle (FB is starting)	INT (MC_CLUTCH_METHOD)	• 0: Invalid (NoClutch) (Direct coupled operation) • 1: Clutch command (ClutchCommand) • 2: Clutch command leading edge (ClutchLeadingEdge) • 3: Clutch command trailing edge (ClutchTrailingEdge) • 4: Address mode (ClutchAddress) • 15: I/O data specification (ClutchSignal)	0: Invalid (NoClutch)
AuxOffControl	Auxiliary shaft clutch OFF control setting		INT (MC_CLUTCH_METHOD)	• 0: Invalid (NoClutch) (OFF control invalid) • 1: Clutch command (ClutchCommand) (One-shot operation) • 2: Clutch command leading edge (ClutchLeadingEdge) • 3: Clutch command trailing edge (ClutchTrailingEdge) • 4: Address mode (ClutchAddress) • 15: I/O data specification (ClutchSignal)	0: Invalid (NoClutch)
AuxReference	Auxiliary shaft clutch reference address setting	At start	INT (MC_CLUTCH_REFERENCE)	• 0: Current position before gear (GearFrontPosition) • 1: Current position per cycle after gear (GearPositionPerCycle)	0: Current position before gear (GearFrontPosition)
AuxOnAddress	Auxiliary shaft clutch ON address	Operation cycle (FB is starting)	LREAL	-10000000000.0 to 10000000000.0	0.0
AuxMovementAmountBeforeOn	Movement amount before auxiliary shaft clutch ON	At completing clutch ON condition	LREAL	-2147483648.0 to 2147483647.0	0.0
AuxOffAddress	Auxiliary shaft clutch OFF address	Operation cycle (FB is starting)	LREAL	-10000000000.0 to 10000000000.0	0.0
AuxMovementAmountBeforeOff	Movement amount before auxiliary shaft clutch OFF	At completing clutch OFF condition	LREAL	-2147483648.0 to 2147483647.0	0.0
AuxSmoothingMethod	Auxiliary shaft clutch smoothing method	At start	INT (MC_CLUTCH_SMOOTHING_METHOD)	• 0: Direct (ClutchSmoothingDisabled) • 1: Time constant method (Exponent) (TimeConstantExponent) • 2: Time constant method (Linear) (TimeConstantLinear) • 3: Slippage method (Exponent) (SlippageExponent) • 4: Slippage method (Linear) (SlippageLinear) • 5: Slippage method (Linear: Input value follow up) (SlippageLinearFollow)	0: Direct (ClutchSmoothingDisabled)
AuxOnSlippageAmount	Slippage amount at auxiliary shaft clutch ON	At turning clutch on	LREAL	0.0 to 2147483647.0	0.0
AuxOffSlippageAmount	Slippage amount at auxiliary shaft clutch OFF	At turning clutch off	LREAL	0.0 to 2147483647.0	0.0

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Auxiliary shaft clutch ON control setting (AdvOutputName.Pr.Clutch.AuxOnControl)

Set the control method for auxiliary shaft clutch ON. The Auxiliary shaft clutch ON control setting (AdvOutputName.Pr.Clutch.AuxOnControl) can be changed during synchronous control. However, changes from settings other than "0: Invalid (NoClutch)" to "0: Invalid (NoClutch)" are not possible.

Setting value	Description
0: Invalid (NoClutch) (Direct coupled operation)	Execute direct coupled operation without clutch control.
1: Clutch command (ClutchCommand)	The clutch is turned on/off by the operations of the Auxiliary shaft clutch command (AdvOutputName.Cd.Clutch.AuxCommand) TRUE/FALSE. (In the clutch command ON/OFF mode, the setting in the Auxiliary shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.AuxOffControl) is not referred to.)
2: Clutch command leading edge (ClutchLeadingEdge)	The clutch is turned on when the Auxiliary shaft clutch command (AdvOutputName.Cd.Clutch.AuxCommand) passes the leading edge (from FALSE to TRUE).
3: Clutch command trailing edge (ClutchTrailingEdge)	The clutch is turned on when the Auxiliary shaft clutch command (AdvOutputName.Cd.Clutch.AuxCommand) passes the trailing edge (from TRUE to FALSE).
4: Address mode (ClutchAddress)	The clutch is turned on when the reference address (the cumulative current position of the auxiliary shaft or the current position per cycle after auxiliary shaft gear) reaches the Auxiliary shaft clutch ON address (AdvOutputName.Pr.Clutch.AuxOnAddress). When the reference address passes through the ON address, the movement amount after the ON address is passed is output as the output movement amount of the clutch. Therefore, the clutch is controlled with the accurate movement amount.
15: I/O data specification (ClutchSignal)	The clutch is turned on when the external input signal set in the Auxiliary shaft clutch ON signal setting (AdvOutputName.Pr.AuxOnClutchSignal) is detected.

Point

- Other clutch parameter settings are not referred to because direct coupled operation is used by setting the Auxiliary shaft clutch ON control setting (AdvOutputName.Pr.Clutch.AuxOnControl) to "0: Invalid (NoClutch)". The Auxiliary shaft clutch forced OFF command (AdvOutputName.Cd.Clutch.AuxForcedOff) and the change of the clutch control setting are ignored during direct coupled operation.
- Changes from settings other than "0: Invalid (NoClutch)" to "0: Invalid (NoClutch)" are not possible during synchronous control. If the setting is changed in that manner, Out of Advanced Synchronous Control Variable Range Warning (error code: 0D3FH) occurs.

■Auxiliary shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.AuxOffControl)

Set the control method for auxiliary shaft clutch OFF.

Setting value	Description
0: Invalid (NoClutch) (OFF control invalid)	Clutch OFF control is not used. Set it only for execution with clutch ON control.
1: Clutch command (ClutchCommand) (One-shot operation)	After Auxiliary shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.AuxOnOffStatus) is turned on, it moves the distance set in Movement amount before auxiliary shaft clutch OFF (AdvOutputName.Pr.Clutch.AuxMovementAmountBeforeOff), then the clutch turns off. (One-shot operation) If the Movement amount before auxiliary shaft clutch OFF (AdvOutputName.Pr.Clutch.AuxMovementAmountBeforeOff) is "0.0", the Auxiliary shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.AuxOnOffStatus) does not turn to "TRUE (Clutch ON status)" in order to turn back off immediately.
2: Clutch command leading edge (ClutchLeadingEdge)	The clutch is turned on when the Auxiliary shaft clutch command (AdvOutputName.Cd.Clutch.AuxCommand) passes the leading edge (from FALSE to TRUE).
3: Clutch command trailing edge (ClutchTrailingEdge)	The clutch is turned on when the Auxiliary shaft clutch command (AdvOutputName.Cd.Clutch.AuxCommand) passes the trailing edge (from TRUE to FALSE).
4: Address mode (ClutchAddress)	The clutch is turned off when the reference address (the cumulative current position of the auxiliary shaft or the current position per cycle after auxiliary shaft gear) reaches the Auxiliary shaft clutch OFF address (AdvOutputName.Pr.Clutch.AuxOffAddress). When the reference address passes through the OFF address, the movement amount after the OFF address is passed is output as the output movement amount of the clutch. Therefore, the clutch is controlled with the accurate movement amount.
15: I/O data specification (ClutchSignal)	The clutch is turned off when the external input signal set in the Auxiliary shaft clutch OFF signal setting (AdvOutputName.Pr.AuxOffClutchSignal) is detected.

■Auxiliary shaft clutch reference address setting (AdvOutputName.Pr.Clutch.AuxReference)

Set the address to be referred to at clutch control.

Note that the processing order of gears and clutches varies by the reference address.

Setting value	Description
0: Current position before gear (GearFrontPosition)	The clutch is controlled by using the input axis cumulative current position set in auxiliary shaft, which is before the auxiliary shaft gear conversion. The movement amount after the clutch control is converted then output through the auxiliary shaft gear. * The clutch processing is performed for the current position of the auxiliary shaft. The current position of auxiliary shaft is used as the reference address when the Auxiliary shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.AuxOffControl) is set to "4: Address mode (ClutchAddress)".
1: Current position per cycle after gear (GearPositionPerCycle)	The clutch is controlled by using the current position per cycle after auxiliary shaft gear. The movement amount after the clutch control is output as it is. * The clutch processing is performed for the current position per cycle after auxiliary shaft gear. The current position per cycle after auxiliary shaft gear is used as the reference address when the Auxiliary shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.AuxOffControl) is set to "4: Address mode (ClutchAddress)".

The unit settings of the following parameters are in position command units of the auxiliary shaft.

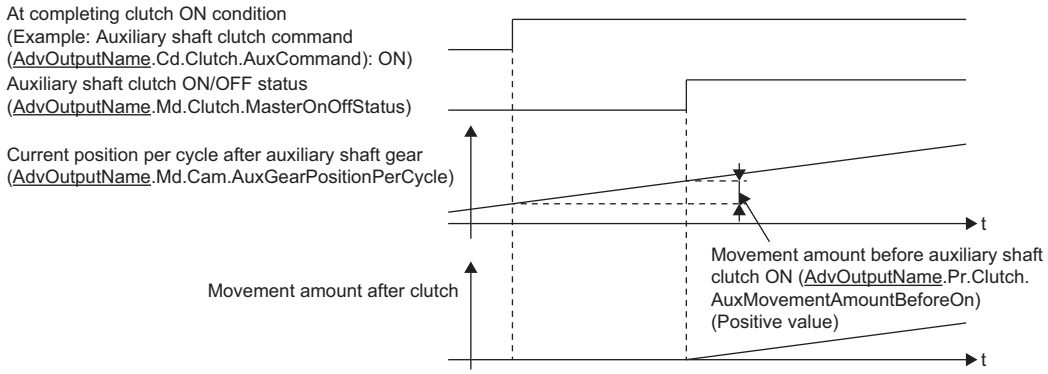
- Auxiliary shaft clutch ON address (AdvOutputName.Pr.Clutch.AuxOnAddress)
- Auxiliary shaft clutch OFF address (AdvOutputName.Pr.Clutch.AuxOffAddress)
- Movement amount before auxiliary shaft clutch ON (AdvOutputName.Pr.Clutch.AuxMovementAmountBeforeOn)
- Movement amount before auxiliary shaft clutch OFF (AdvOutputName.Pr.Clutch.AuxMovementAmountBeforeOff)
- Slippage amount at auxiliary shaft clutch ON (AdvOutputName.Pr.Clutch.AuxOnSlippageAmount)
- Slippage amount at auxiliary shaft clutch OFF (AdvOutputName.Pr.Clutch.AuxOffSlippageAmount)

■Auxiliary shaft clutch ON address (AdvOutputName.Pr.Clutch.AuxOnAddress)

Set the clutch ON address when "4: Address mode (ClutchAddress)" is set in the Auxiliary shaft clutch Main shaft ON clutch control setting (AdvOutputName.Pr.Clutch.AuxOnControl). When "1: Current position per cycle after gear (GearPositionPerCycle)" is set in the Auxiliary shaft clutch reference address setting (AdvOutputName.Pr.Clutch.AuxReference), the setting address is converted for control within the range from 0.0 to (length per cycle - 0.00001).

Setting value
-10000000000.0 ≤ Auxiliary shaft clutch ON address (AdvOutputName.Pr.Clutch.AuxOnAddress) < 10000000000.0

Ex.



Length per cycle: 20000.0

The ON address is controlled as "19000.0" when the setting value is "-1000.0".

■Movement amount before auxiliary shaft clutch ON (AdvOutputName.Pr.Clutch.AuxMovementAmountBeforeOn)

Set the movement amount for the reference address with a signed number regarding from when the clutch ON condition is met until when the clutch turns on.

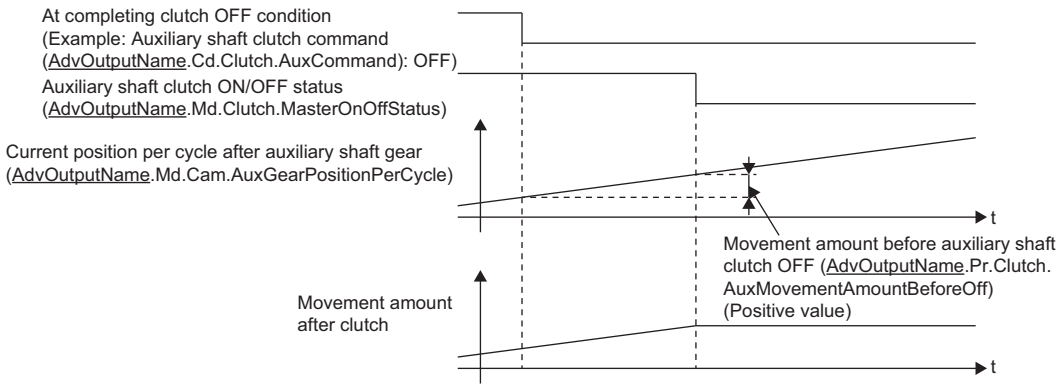
Setting value	Description
0.00001 to 2147483647.0 (Positive value)	Used when the reference address is increasing in direction.
0.0	No movement (The clutch turns on at the same time as when the ON condition is met.)
-2147483648.0 to -0.00001 (Negative value)	Used when the reference address is decreasing in direction.

■Auxiliary shaft clutch OFF address (AdvOutputName.Pr.Clutch.AuxOffAddress)

Set the clutch OFF address when "4: Address mode (ClutchAddress)" is set in the Auxiliary shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.AuxOffControl). When "1: Current position per cycle after gear (GearPositionPerCycle)" is set in the Auxiliary shaft clutch reference address setting (AdvOutputName.Pr.Clutch.AuxReference), the setting address is converted for control within the range from 0.0 to (length per cycle - 0.00001).

Setting value
-10000000000.0 ≤ Auxiliary shaft clutch OFF address (AdvOutputName.Pr.Clutch.AuxOffAddress) < 10000000000.0

Ex.



Length per cycle: 20000.0

The OFF address is controlled as "60.0" when the setting value is "40060.0".

■Movement amount before auxiliary shaft clutch OFF (AdvOutputName.Pr.Clutch.AuxMovementAmountBeforeOff)

Set the movement amount for the reference address with a signed number regarding from when the auxiliary shaft clutch OFF condition is met until when the clutch turns off.

Setting value	Description
0.00001 to 2147483647.0 (Positive value)	Used when the reference address is increasing in direction.
0.0	No movement (The clutch turns off at the same time as when the OFF condition is met.)
-2147483648.0 to -0.00001 (Negative value)	Used when the reference address is decreasing in direction.

■Auxiliary shaft clutch smoothing method (AdvOutputName.Pr.Clutch.AuxSmoothingMethod)

Set the smoothing method for clutch ON/OFF.

Setting value	Description
0: Direct (ClutchSmoothingDisabled)	No smoothing for the auxiliary shaft clutch.
1: Time constant method (Exponent) (TimeConstantExponent)	Smoothing with an exponential curve based on the time constant setting.
2: Time constant method (Linear) (TimeConstantLinear)	Smoothing with linear acceleration/deceleration based on the time constant setting.
3: Slippage method (Exponent) (SlippageExponent)	Smoothing with an exponential curve based on the slippage amount setting.
4: Slippage method (Linear) (SlippageLinear)	Smoothing with linear acceleration/deceleration based on the slippage amount setting.
5: Slippage method (Linear: Input value follow up) (SlippageLinearFollow)	Smoothing with linear acceleration/deceleration (input value follow up) based on the slippage amount setting.

■Slippage amount at auxiliary shaft clutch ON (AdvOutputName.Pr.Clutch.AuxOnSlippageAmount)

Set the slippage amount at clutch ON when any of the following is set in the Auxiliary shaft clutch smoothing method (AdvOutputName.Pr.Clutch.AuxSmoothingMethod). "3: Slippage method (Exponent) (SlippageExponent)", "4: Slippage method (Linear) (SlippageLinear)", or "5: Slippage method (Linear: Input value follow up) (SlippageLinearFollow)".
Set the slippage amount in units based on the setting in the Auxiliary shaft clutch reference address setting (AdvOutputName.Pr.Clutch.AuxReference).
If the set amount is negative, slippage amount at clutch ON is controlled as 0 (direct).

Point

Do not set digits after the decimal point when "3: Slippage method (Exponent) (SlippageExponent)" is set in the Auxiliary shaft clutch smoothing method (AdvOutputName.Pr.Clutch.AuxSmoothingMethod). If set, smoothing is performed with the digits after the decimal point ignored.

■Slippage amount at auxiliary shaft clutch OFF (AdvOutputName.Pr.Clutch.AuxOffSlippageAmount)

Set the slippage amount at clutch OFF when any of the following is set in the Auxiliary shaft clutch smoothing method (AdvOutputName.Pr.Clutch.AuxSmoothingMethod). "3: Slippage method (Exponent) (SlippageExponent)", "4: Slippage method (Linear) (SlippageLinear)", or "5: Slippage method (Linear: Input value follow up) (SlippageLinearFollow)".
Set the slippage amount in units based on the setting in the Auxiliary shaft clutch reference address setting (AdvOutputName.Pr.Clutch.AuxReference).
If the set amount is negative, slippage amount at clutch OFF is controlled as 0 (direct).

Point

Do not set digits after the decimal point when "3: Slippage method (Exponent) (SlippageExponent)" is set in the Auxiliary shaft clutch smoothing method (AdvOutputName.Pr.Clutch.AuxSmoothingMethod). If set, smoothing is performed with the digits after the decimal point ignored.

Clutch monitor of output axis monitor data (AdvOutputName.Md.Clutch.)

Variable name	Name	Import*1	Data type*1	Monitor value
AuxOnOffStatus	Auxiliary shaft clutch ON/OFF status	Operation cycle (FB is starting)	BOOL	• FALSE: Clutch OFF status • TRUE: Clutch ON status
AuxSmoothingStatus	Auxiliary shaft clutch smoothing status		BOOL	• FALSE: Not on clutch smoothing • TRUE: On clutch smoothing
AuxCumulativeSlippage	Auxiliary shaft clutch slippage (accumulative)		LREAL	-2147483648.0 to 2147483647.0

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Auxiliary shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.AuxOnOffStatus)

The auxiliary shaft clutch ON/OFF status is stored.

■Auxiliary shaft clutch smoothing status (AdvOutputName.Md.Clutch.AuxSmoothingStatus)

The smoothing status of the auxiliary shaft clutch is stored.

The status is updated by the Auxiliary shaft clutch smoothing method (AdvOutputName.Pr.Clutch.AuxSmoothingMethod).

Method	Description
Time constant method	The status is always "TRUE: On clutch smoothing" during the clutch ON status. The status will be "FALSE: Not on clutch smoothing" when the clutch is turned off and smoothing is completed.
Slippage method	The status is "TRUE: On clutch smoothing" until the clutch accumulative slippage amount reaches the slippage at clutch ON when the clutch is turned on. The status will change to "FALSE: Not on clutch smoothing" when the clutch accumulative slippage amount reaches the slippage at clutch ON. The status is "TRUE: On clutch smoothing" until the clutch accumulative slippage amount reaches 0 when the clutch is turned off. The status will change to "FALSE: Not on clutch smoothing" when the clutch accumulative slippage amount reaches 0.

■Auxiliary shaft clutch slippage (accumulative) (AdvOutputName.Md.Clutch.AuxCumulativeSlippage)

The accumulative slippage amount with the slippage method during clutch smoothing is stored as a signed value.

The absolute value of the accumulative slippage increases to reach the slippage at clutch ON during clutch ON.

The absolute value of the accumulative slippage decreases to reach "0.0" during clutch OFF.

Monitoring of the accumulative slippage is used to check the smoothing progress with the slippage method.

Clutch control data of output axis control data (AdvOutputName.Cd.Clutch.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
AuxCommand	Auxiliary shaft clutch command	Operation cycle (FB is starting)	BOOL	• FALSE: Clutch command OFF • TRUE: Clutch command ON	FALSE
AuxInvalidCommand	Auxiliary shaft clutch control invalid command		BOOL	• FALSE: Clutch control valid • TRUE: Clutch control invalid	FALSE
AuxForcedOff	Auxiliary shaft clutch forced OFF command		BOOL	• FALSE: Clutch normal control • TRUE: Clutch forced OFF	FALSE
AuxClutchSmoothingTimeConstant	Auxiliary shaft clutch smoothing time constant change value	At start	INT	0 to 5000 [ms]	0

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Auxiliary shaft clutch command (AdvOutputName.Cd.Clutch.AuxCommand)

Sets ON/OFF for the auxiliary shaft clutch command.

This command is used when any of the following is set in the Auxiliary shaft clutch ON control setting (AdvOutputName.Pr.Clutch.AuxOnControl).

- 1: Clutch command (ClutchCommand)
- 2: Clutch command leading edge (ClutchLeadingEdge)
- 3: Clutch command trailing edge (ClutchTrailingEdge)

The status just before synchronous control starts is considered as clutch command OFF. If synchronous control is started while the clutch command is on, the condition is established just after starting synchronous control, by setting "2: Clutch command leading edge (ClutchLeadingEdge)". The condition is not established just after starting synchronous control, by setting "3: Clutch command trailing edge (ClutchTrailingEdge)".

■Auxiliary shaft clutch control invalid command (AdvOutputName.Cd.Clutch.AuxInvalidCommand)

The auxiliary shaft clutch control is invalid if "TRUE: Clutch control invalid" is set. The clutch ON/OFF status maintained is the one before clutch control becomes invalid.

Clutch control will not become invalid during movement before clutch ON and during movement before clutch OFF. Instead, clutch control will become invalid after movement is completed.

■Auxiliary shaft clutch forced OFF command (AdvOutputName.Cd.Clutch.AuxForcedOff)

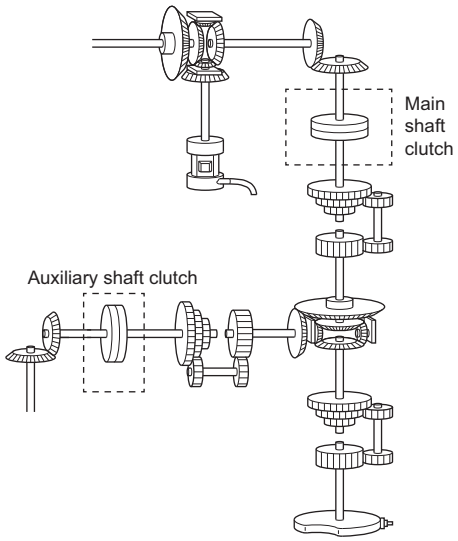
Set "TRUE: Clutch forced OFF" to force the clutch OFF. The output value from the clutch becomes "0" immediately, even during clutch smoothing. The slippage (accumulative) amount is set to 0 if smoothing with a slippage method.

Reset to "FALSE: Clutch normal control" to restart the clutch control from the clutch OFF status after using the clutch forced OFF command.

■Auxiliary shaft clutch smoothing time constant change value (AdvOutputName.Cd.Clutch.AuxClutchSmoothingTimeConstant)

The smoothing time constant of the auxiliary shaft clutch is changed. The setting is imported when MCv_AdvancedSync (Advanced Synchronous Control) is started.

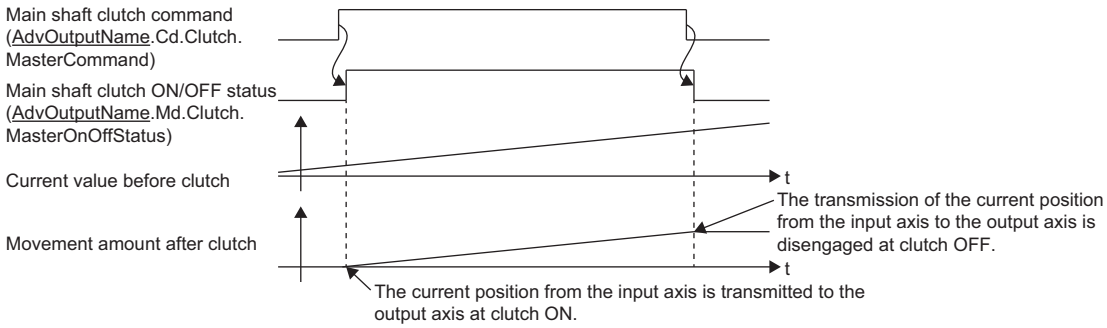
Setting value	Description
When a negative value is set	No smoothing.
When 0 is set	Smoothing based on the setting value of the Auxiliary shaft clutch smoothing time constant (AdvOutputName.PrConst.AuxClutchSmoothingTimeConstant).
When a positive value is set	Smoothing based on the setting value of the Auxiliary shaft clutch smoothing time constant change value (AdvOutputName.Cd.Clutch.AuxClutchSmoothingTimeConstant).



Set within the following setting range.

If the set value exceeds the range below, Out of Advanced Synchronous Control Variable Range Warning (error code: 0D3FH) occurs, and smoothing is executed based on the setting value of the Auxiliary shaft clutch smoothing time constant (AdvOutputName.PrConst.AuxClutchSmoothingTimeConstant).

Setting range
Auxiliary shaft clutch smoothing time constant (AdvOutputName.PrConst.AuxClutchSmoothingTimeConstant) > Auxiliary shaft clutch smoothing time constant change value (AdvOutputName.Cd.Clutch.AuxClutchSmoothingTimeConstant)



Clutch

The clutch is used to transmit/disengage command pulses from the main/auxiliary shaft input through turning the clutch on/off, which controls the operation/stop of the output axis.
A clutch can be configured for the main and auxiliary shaft modules.

When the conditions set in Main shaft clutch ON control setting (AdvOutputName.Pr.Clutch.MasterOnControl) and Auxiliary shaft clutch ON control setting (AdvOutputName.Pr.Clutch.AuxOnControl) are satisfied, the clutch status changes from FALSE to TRUE. When the conditions set in Main shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.MasterOffControl) and Auxiliary shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.AuxOffControl) are satisfied, the clutch status changes from TRUE to FALSE.
The current position of the input axis is transmitted to the output axis at the timing of the clutch ON/OFF status changing to TRUE.
The input and output axes are disengaged at the timing of the clutch ON/OFF status turning to FALSE.
The following explains the operations of clutch ON/OFF.

Ex.
When the Main shaft clutch ON control setting (AdvOutputName.Pr.Clutch.MasterOnControl) is set to "1: Clutch command (ClutchCommand)"

The movement amount of the output axis before clutch ON and OFF can be adjusted with parameters of the movement amount before clutch ON or the movement amount before clutch OFF.
The smoothing time constant can be set to smooth the operation of the output axis before and after clutch ON/OFF.

Clutch control setting

Set the clutch ON and OFF control methods separately. Set the ON control methods in Main shaft clutch ON control setting (AdvOutputName.Pr.Clutch.MasterOnControl) and Auxiliary shaft clutch ON control setting (AdvOutputName.Pr.Clutch.AuxOnControl), and the OFF control methods in Main shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.MasterOffControl) and Auxiliary shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.AuxOffControl).

The clutch control setting can be changed during synchronous control. However, changes from settings other than "0: Invalid (NoClutch) (Direct coupled operation)" to "0: Invalid (NoClutch) (Direct coupled operation)" are not possible in the ON control mode.

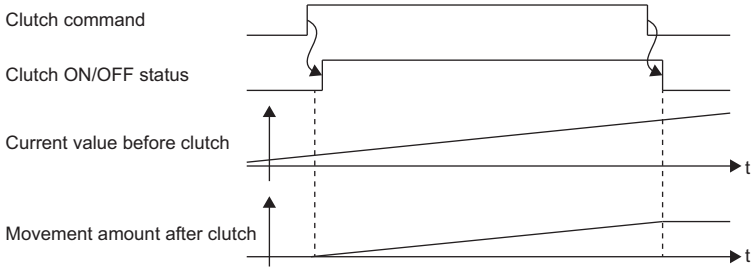
Item	Setting item		Setting value
	Main shaft clutch	Auxiliary shaft clutch	
Clutch ON control setting	Main shaft clutch ON control setting (AdvOutputName.Pr.Clutch.MasterOnControl)	Auxiliary shaft clutch ON control setting (AdvOutputName.Pr.Clutch.AuxOnControl)	• 0: Invalid (NoClutch) (Direct coupled operation) • 1: Clutch command (ClutchCommand) • 2: Clutch command leading edge (ClutchLeadingEdge) • 3: Clutch command trailing edge (ClutchTrailingEdge) • 4: Address mode (ClutchAddress) • 15: I/O data specification (ClutchSignal)
Clutch OFF control setting	Main shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.MasterOffControl)	Auxiliary shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.AuxOffControl)	• 0: Invalid (NoClutch) (OFF control invalid) • 1: Clutch command (ClutchCommand) (One-shot operation) • 2: Clutch command leading edge (ClutchLeadingEdge) • 3: Clutch command trailing edge (ClutchTrailingEdge) • 4: Address mode (ClutchAddress) • 15: I/O data specification (ClutchSignal)

When the clutch ON condition and the clutch OFF condition are completed simultaneously within one operation cycle, both clutch ON and OFF processing are executed within one operation cycle. Therefore, the clutch changes from off to on and again to off at the clutch OFF status, and changes from on to off and again to on at the clutch ON status.

The clutch ON/OFF operations for clutch ON and OFF control settings are shown below.

■Main shaft clutch ON control setting (AdvOutputName.Pr.Clutch.MasterOnControl)/Auxiliary shaft clutch ON control setting (AdvOutputName.Pr.Clutch.AuxOnControl)

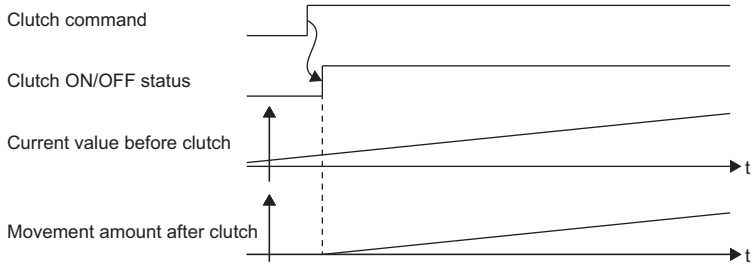
- Invalid (Direct coupled operation): Execute direct coupled operation without clutch control.



Point

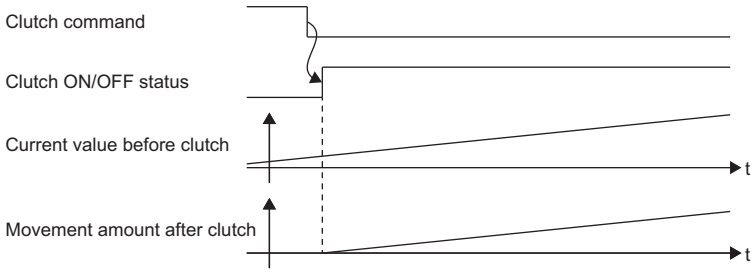
- Other clutch parameter settings are not referred to because direct coupled operation is used by setting the Main shaft clutch ON control setting (AdvOutputName.Pr.Clutch.MasterOnControl) and the Auxiliary shaft clutch ON control setting (AdvOutputName.Pr.Clutch.AuxOnControl) to "0: Invalid (NoClutch) (Direct coupled operation)". The "clutch forced OFF command" and the change of the clutch control setting are ignored during direct coupled operation.
- Changes from settings other than "0: Invalid (NoClutch) (Direct coupled operation)" to "0: Invalid (NoClutch) (Direct coupled operation)" are not possible during synchronous control. If the setting is changed in that manner, Out of Advanced Synchronous Control Variable Range Warning (error code: 0D3FH) occurs.

• Clutch command

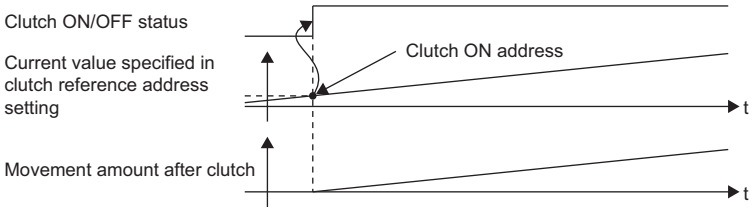


The clutch is turned on/off by the TRUE/FALSE operation of "clutch command".

When "1: Clutch command (ClutchCommand)" is set in the Main shaft clutch ON control setting (AdvOutputName.Pr.Clutch.MasterOnControl) and the Auxiliary shaft clutch ON control setting (AdvOutputName.Pr.Clutch.AuxOnControl), the settings of the Main shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.MasterOffControl) and the Auxiliary shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.AuxOffControl) are not referred to.



Item	Main shaft clutch	Auxiliary shaft clutch
Clutch command	Main shaft clutch command (AdvOutputName.Cd.Clutch.MasterCommand)	Auxiliary shaft clutch command (AdvOutputName.Cd.Clutch.AuxCommand)
Clutch ON/OFF status	Main shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.MasterOnOffStatus)	Auxiliary shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.AuxOnOffStatus)

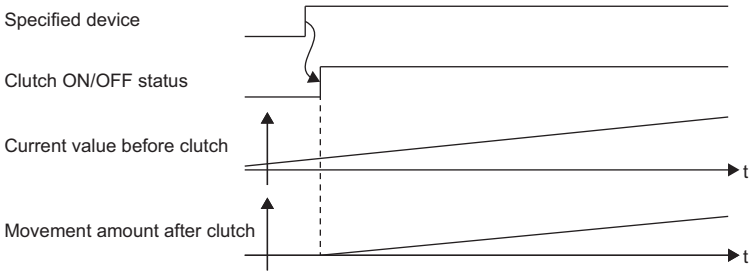


• Clutch command leading edge: The clutch is turned on when the "clutch command" passes the leading edge (from FALSE to TRUE).

• Clutch command trailing edge: The clutch is turned on when the "clutch command" passes the trailing edge (from TRUE to FALSE).

• Address mode: The clutch is turned on when the "reference address" reaches "Clutch ON address". When the reference address passes through the ON address, the movement amount after the ON address is passed is output as the output movement amount of the clutch. Therefore, the clutch is controlled with the accurate movement amount.

Item	Main shaft clutch	Auxiliary shaft clutch
Reference address	The current position specified in the Main shaft clutch reference address setting (AdvOutputName.Pr.Clutch.MasterReference) • 0: Current position before gear (GearFrontPosition)*1 • 1: Current position per cycle after gear (GearPositionPerCycle)*2	The current position specified in the Auxiliary shaft clutch reference address setting (AdvOutputName.Pr.Clutch.AuxReference) • 0: Current position before gear (GearFrontPosition)*3 • 1: Current position per cycle after gear (GearPositionPerCycle)*4
Clutch ON address	Main shaft clutch ON address (AdvOutputName.Pr.Clutch.MasterOnAddress)	Auxiliary shaft clutch ON address (AdvOutputName.Pr.Clutch.AuxOnAddress)
Clutch ON/OFF status	Main shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.MasterOnOffStatus)	Auxiliary shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.AuxOnOffStatus)



*1 As a monitor, the Current position after composite main shaft gear (AdvOutputName.Md.Cam.MasterCompositeGearSetPosition) is referred to.

*2 As a monitor, the Current position per cycle after main shaft gear (AdvOutputName.Md.Cam.MasterGearPositionPerCycle) is referred to.

*3 As a monitor, the cumulative current position of the auxiliary shaft (the Cumulative current position (AdvInputName.Md.CumulativePosition) of the input axis set in the auxiliary shaft) is referred to.

*4 As a monitor, the Current position per cycle after auxiliary shaft gear (AdvOutputName.Md.Cam.AuxGearPositionPerCycle) is referred to.

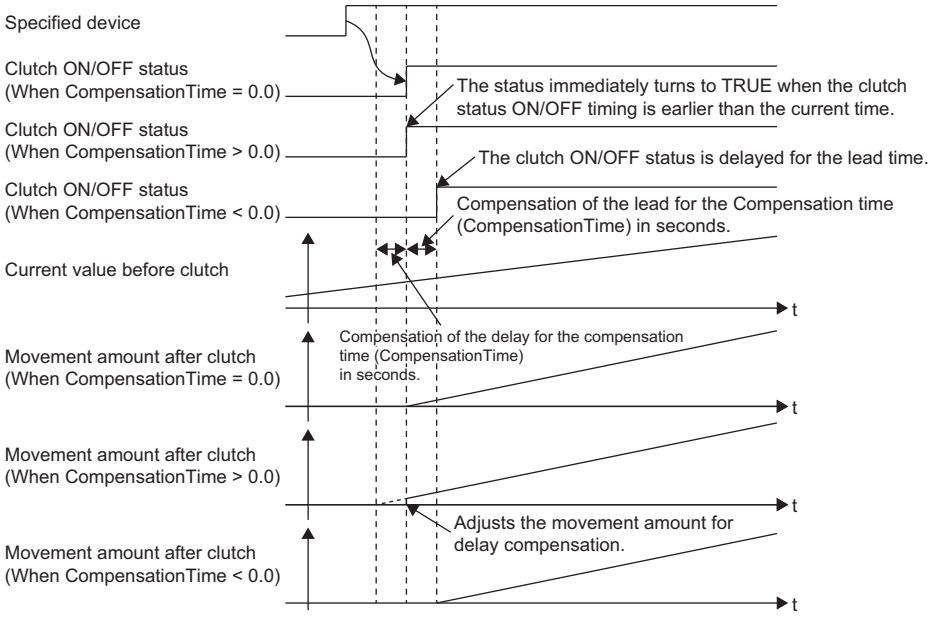
• I/O data specification: The clutch is turned on at an input signal detection.

When using an external signal, set the following clutch ON signal settings.

Item	Main shaft	Auxiliary shaft
Clutch ON signal setting	Main shaft clutch ON signal setting (AdvOutputName.Pr.MasterOnClutchSignal)	Auxiliary shaft clutch ON signal setting (AdvOutputName.Pr.AuxOnClutchSignal)

The type for the clutch ON signal setting is SIGNAL_SELECT (Signal Select). The setting range of the clutch ON signal setting is as follows.

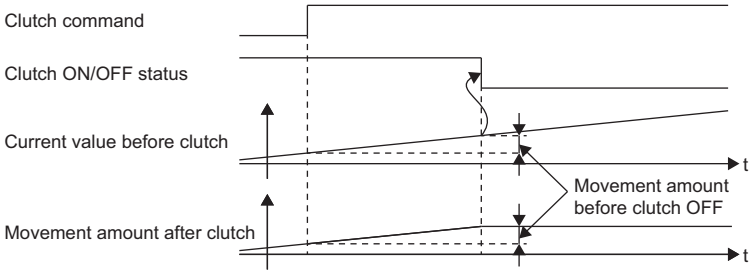
Structure	Variable name	Type	Setting range*1
SIGNAL_SELECT (Signal Select)	Source (Signal). Target (Target)	TARGET_REF	■ Type • BOOL ■Data type • [OBJ]*2*3 • [VAR] • [DEV] • [LINK]*4
	Detection (Signal detection method)	INT (MC_SIGNAL_LOGIC)	• 2: Detection at FALSE → TRUE (rising edge) (RisingEdge) • 3: Detection at TRUE → FALSE (falling edge) (FallingEdge) • 4: Detection at rising edge/falling edge (BothEdges)
	CompensationTime (Compensation time)*5	LREAL	-5.0 to 5.0 [s]
	FilterTime (Filter time)	LREAL	0.0 [s]



*1 In the following cases, Out of Parameter Range (Advanced Synchronous Control Output Axis) (error code: 1A66H) occurs.
· The target modification is omitted when [OBJ] is specified as data type
· Detection (Signal detection method) of data type [LINK] is set to "4: Detection at rising edge/falling edge (BothEdges)"
· Source.Target is omitted or the target does not exist
· The set value in the Signal detection method (Detection), the Compensation time (CompensationTime), or the Filter time (FilterTime) is out of range

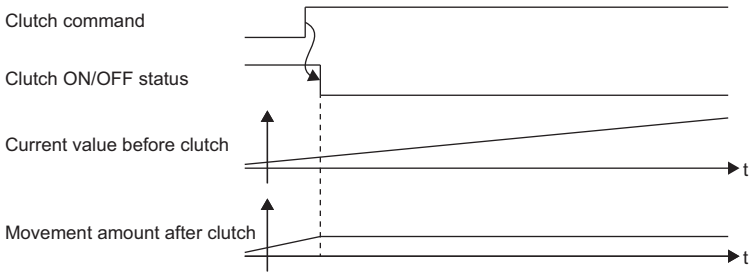
*2 If the Axis Emulate function is enabled and a station address is set for the referred station, the emulating object will be referred to.

*3 External signal high-accuracy input can be used. When using the external signal high-accuracy input, set the Detection (Signal detection method) to "4: Detection at rising edge/falling edge (BothEdges)". For details, refer to the following.
☞ Page 1164 External Signal High-Accuracy Input
For the high-accuracy settings, refer to the following.
☞ Page 2152 Connection to Servo Amplifier That Supports CC-Link IE TSN



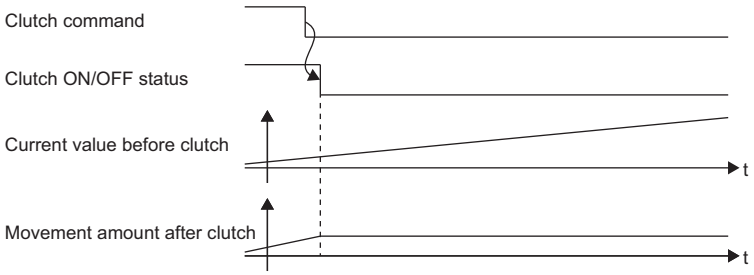
*4 Use the external signal high-accuracy input for data type [LINK] For details, refer to the following.
☞ Page 1164 External Signal High-Accuracy Input

*5 The detection time of an input signal can be compensated by setting the Compensation time (CompensationTime). Set a positive value to compensate the delay of the input signal, and set a negative value to compensate the lead. As shown below, the clutch ON/OFF status varies depending on the compensation time setting.
When delay is compensated with the Compensation time (CompensationTime), the movement amount after clutch may change rapidly. Adjust so that the movement amount changes gradually with the smoothing function of the clutch and output axis.



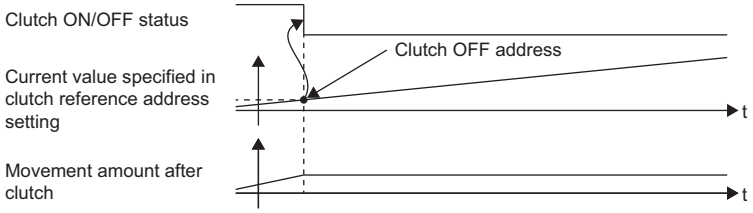
■Main shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.MasterOffControl)/Auxiliary shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.AuxOffControl)

- Invalid (OFF control invalid): Clutch OFF control is not used. Set it only for execution with clutch ON control.
- Clutch command (One-shot operation): The clutch is turned off after moving the distance "Movement amount before clutch OFF" after the "clutch ON/OFF status" changes from FALSE to TRUE.
  If the "Movement amount before clutch OFF" is "0.0", the "Clutch ON/OFF status" does not turn on in order to turn back off immediately.



Item	Main shaft clutch	Auxiliary shaft clutch
Clutch command	Main shaft clutch command (AdvOutputName.Cd.Clutch.MasterCommand)	Auxiliary shaft clutch command (AdvOutputName.Cd.Clutch.AuxCommand)
Clutch ON/OFF status	Main shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.MasterOnOffStatus)	Auxiliary shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.AuxOnOffStatus)
Movement amount before clutch OFF	Movement amount before main shaft clutch OFF (AdvOutputName.Pr.Clutch.MasterMovementAmountBeforeOff)	Movement amount before auxiliary shaft clutch OFF (AdvOutputName.Pr.Clutch.AuxMovementAmountBeforeOff)

- Clutch command leading edge: The clutch is turned off when the "clutch command" passes the leading edge (from FALSE to TRUE).

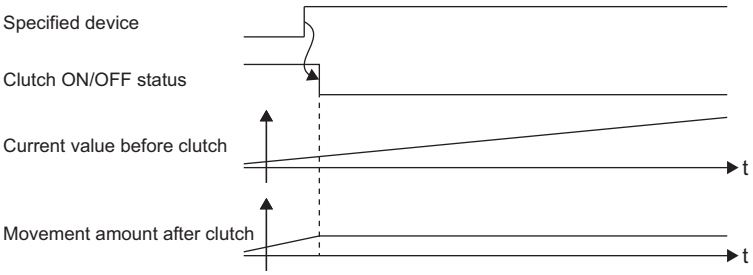


- Clutch command trailing edge: The clutch is turned off when the "clutch command" passes the trailing edge (from TRUE to FALSE).

• Address mode: The clutch is turned off when the "reference address" reaches "Clutch OFF address".

When the reference address passes through the OFF address, the movement amount before the OFF address is passed is output as the output movement amount of the clutch. Therefore, the clutch is controlled with the accurate movement amount.

Item	Main shaft clutch	Auxiliary shaft clutch
Reference address	The current position specified in the Main shaft clutch reference address setting (AdvOutputName.Pr.Clutch.MasterReference) • 0: Current position before gear (GearFrontPosition)*1 • 1: Current position per cycle after gear (GearPositionPerCycle)*2	The current position specified in the Auxiliary shaft clutch reference address setting (AdvOutputName.Pr.Clutch.AuxReference) • 0: Current position before gear (GearFrontPosition)*3 • 1: Current position per cycle after gear (GearPositionPerCycle)*4
Clutch OFF address	Main shaft clutch OFF address (AdvOutputName.Pr.Clutch.MasterOffAddress)	Auxiliary shaft clutch OFF address (AdvOutputName.Pr.Clutch.AuxOffAddress)
Clutch ON/OFF status	Main shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.MasterOnOffStatus)	Auxiliary shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.AuxOnOffStatus)



*1 As a monitor, the Current position after composite main shaft gear (AdvOutputName.Md.Cam.MasterCompositeGearSetPosition) is referred to.

*2 As a monitor, the Current position per cycle after main shaft gear (AdvOutputName.Md.Cam.MasterGearPositionPerCycle) is referred to.

*3 As a monitor, the cumulative current position of the auxiliary shaft (the Cumulative current position (AdvInputName.Md.CumulativePosition) of the input axis set in the auxiliary shaft) is referred to.

*4 As a monitor, the Current position per cycle after auxiliary shaft gear (AdvOutputName.Md.Cam.AuxGearPositionPerCycle) is referred to.

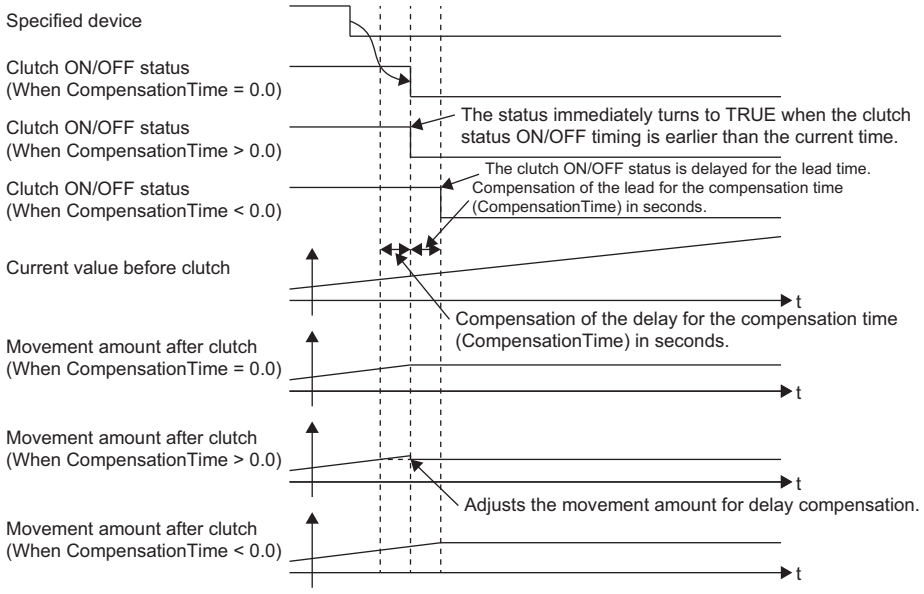
• I/O data specification: The clutch is turned off at an input signal detection.

When using an external signal for I/O data specification, set the following clutch OFF signal settings

Item	Main shaft	Auxiliary shaft
Clutch OFF signal setting	Main shaft clutch OFF signal setting (AdvOutputName.Pr.MasterOffClutchSignal)	Auxiliary shaft clutch OFF signal setting (AdvOutputName.Pr.AuxOffClutchSignal)

The type for the OFF clutch signal setting is SIGNAL_SELECT (Signal select). The setting range of the clutch OFF signal setting is as follows.

Structure	Variable name	Type	Setting range*1
SIGNAL_SELECT (Signal Select)	Source (Signal). Target (Target)	TARGET_REF	■ Type • BOOL ■Data type • [OBJ]*2*3 • [VAR] • [DEV] • [LINK]*4
	Detection (Signal detection method)	INT (MC_SIGNAL_LOGIC)	• 2: Detection at FALSE → TRUE (rising edge) (RisingEdge) • 3: Detection at TRUE → FALSE (falling edge) (FallingEdge) • 4: Detection at rising edge/falling edge (BothEdges)
	CompensationTime (Compensation time)*5	LREAL	-5.0 to 5.0 [s]
	FilterTime (Filter time)	LREAL	0.0 [s]



*1 In the following cases, Out of Parameter Range (Advanced Synchronous Control Output Axis) (error code: 1A66H) occurs.
· The target modification is omitted when [OBJ] is specified as data type
· Detection (Signal detection method) of data type [LINK] is set to "4: Detection at rising edge/falling edge (BothEdges)"
· Source.Target is omitted or the target does not exist
· The set value in the Signal detection method (Detection), the Compensation time (CompensationTime), or the Filter time (FilterTime) is out of range

*2 If the Axis Emulate function is enabled and a station address is set for the referred station, the emulating object will be referred to.

*3 The external signal high-accuracy input is available. When using the external signal high-accuracy input, set the Detection (Signal detection method) to "4: Detection at rising edge/falling edge (BothEdges)". For details, refer to the following.
☞ Page 1164 External Signal High-Accuracy Input
For the high-accuracy settings, refer to the following.
☞ Page 2152 Connection to Servo Amplifier That Supports CC-Link IE TSN

*4 Use the external signal high-accuracy input for data type [LINK] Set Detection (Signal Detection Method) to "2: Detection at FALSE → TRUE (rising edge) (Rising Edge)" or "3: Detection at TRUE → FALSE (falling edge) (FallingEdge)". For details, refer to the following.
☞ Page 1164 External Signal High-Accuracy Input

*5 The detection time of an input signal can be compensated by setting the Compensation time (CompensationTime). Set a positive value to compensate the delay of the input signal, and set a negative value to compensate the lead. As shown below, the clutch ON/OFF status varies depending on the compensation time setting.
When delay is compensated with the Compensation time (CompensationTime), the movement amount after clutch may change rapidly. Adjust so that the movement amount changes gradually with the smoothing function of the clutch and output axis.

Smoothing method for clutch

Set the clutch smoothing method in Main shaft clutch smoothing method (AdvOutputName.Pr.Clutch.MasterSmoothingMethod) and "Auxiliary shaft clutch smoothing method (AdvOutputName.Pr.Clutch.AuxSmoothingMethod)".

The following methods are available for clutch smoothing.

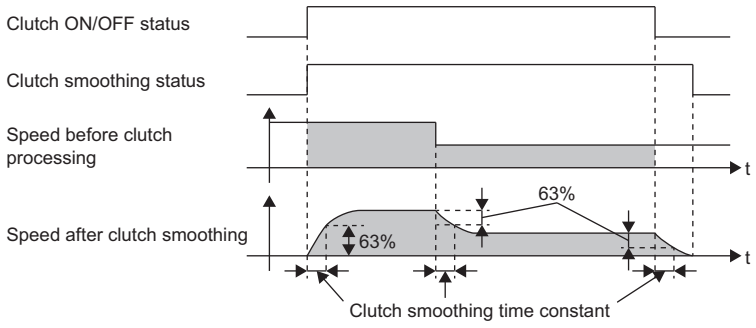
- Time constant method smoothing
- Slippage method smoothing

When not using clutch smoothing, set "0: Direct" in the clutch smoothing method.

Item	Setting item		Setting value
	Main shaft clutch	Auxiliary shaft clutch	
Clutch smoothing method	Main shaft clutch smoothing method (AdvOutputName.Pr.Clutch.MasterSmoothingMethod)	Auxiliary shaft clutch smoothing method (AdvOutputName.Pr.Clutch.AuxSmoothingMethod)	• 0: Direct (ClutchSmoothingDisabled) • 1: Time constant method (Exponent) (TimeConstantExponent) • 2: Time constant method (Linear) (TimeConstantLinear) • 3: Slippage method (Exponent) (SlippageExponent) • 4: Slippage method (Linear) (SlippageLinear) • 5: Slippage method (Linear: Input value follow up) (SlippageLinearFollow)

The operation of each smoothing method is shown below.

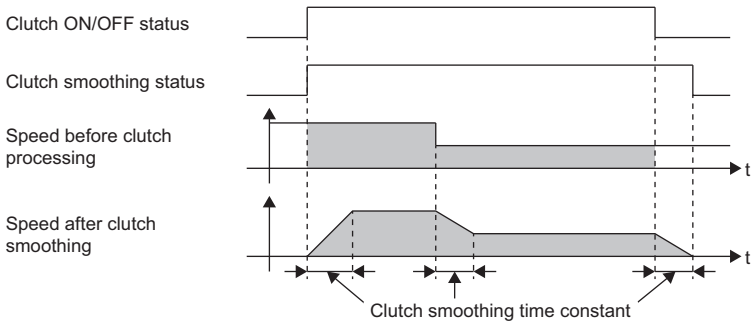
■Time constant method smoothing



Smoothing is executed with the time constant set in "smoothing time constant" at clutch ON/OFF. After clutch ON smoothing is complete, smoothing is executed with the time constant when the speed of the input value changes.

As shown below, the movement amount while the clutch changes from on to off does not change after clutch smoothing.

Movement amount after clutch smoothing = Movement amount before clutch smoothing



Item	Setting item		Setting value
	Main shaft clutch	Auxiliary shaft clutch	
Clutch smoothing time constant	Main shaft clutch smoothing time constant (AdvOutputName.PrConst.MasterClutchSmoothingTimeConstant)	Auxiliary shaft clutch smoothing time constant (AdvOutputName.PrConst.AuxClutchSmoothingTimeConstant)	0 to 5000 [ms]

- Time constant method exponential curve smoothing: Set "1: Time constant method (Exponential) (TimeConstantExponent)" in the "clutch smoothing method".

Item	Main shaft clutch	Auxiliary shaft clutch
Clutch ON/OFF status	Main shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.MasterOnOffStatus)	Auxiliary shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.AuxOnOffStatus)
Clutch smoothing status	Main shaft clutch smoothing status (AdvOutputName.Md.Clutch.MasterSmoothingStatus)	Auxiliary shaft clutch smoothing status (AdvOutputName.Md.Clutch.AuxSmoothingStatus)

• Time constant method linear acceleration/deceleration smoothing: Set "2: Time constant method (Linear) (TimeConstantLinear)" in the "clutch smoothing method".

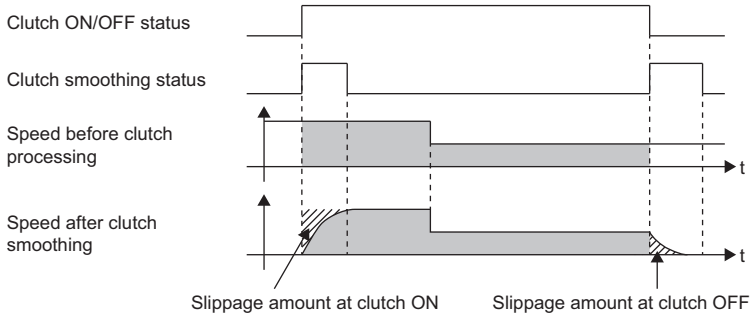
■Slippage method smoothing

Smoothing is executed with the value in "slippage at clutch ON" when the clutch turns on, and with "slippage at clutch OFF" when the clutch turns off.

Because smoothing is still executed with the set slippage amount when the input speed to the clutch changes, the position of clutch ON/OFF can be controlled without being affected by speed changes.

A direct operation follows after completing clutch ON smoothing.

The movement amount while the clutch changes from on to off is as follows after clutch smoothing.



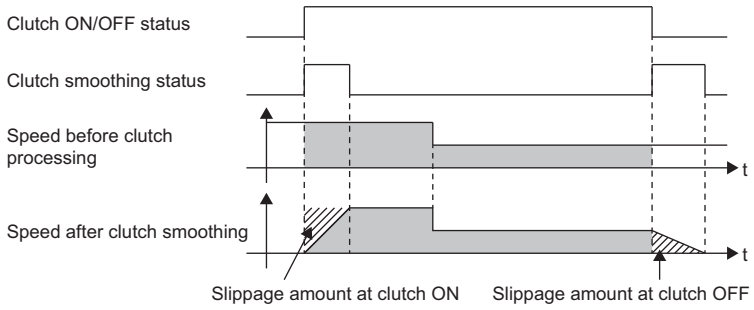
Movement amount after clutch smoothing = Movement amount before clutch smoothing + (Slippage amount at OFF - Slippage amount at ON)

Item	Setting item		Setting value
	Main shaft clutch	Auxiliary shaft clutch	
Slippage amount at clutch ON	Slippage amount at main shaft clutch ON (AdvOutputName.Pr.Clutch.MasterOnSlippageAmount)	Slippage amount at auxiliary shaft clutch ON (AdvOutputName.Pr.Clutch.AuxOnSlippageAmount)	0 to 2147483647 [Main shaft position command units*1/ auxiliary shaft position command units*2]
Slippage amount at clutch OFF	Slippage amount at main shaft clutch OFF (AdvOutputName.Pr.Clutch.MasterOffSlippageAmount)	Slippage amount at auxiliary shaft clutch OFF (AdvOutputName.Pr.Clutch.AuxOffSlippageAmount)	

*1 The position command unit of the axis set as the Master axis (Master) of MCv_AdvancedSync (Advanced Synchronous Control).

*2 The position command unit of the axis set as the Auxiliary axis (AdvOutputName.Pr.AuxAxis).

• Slippage method exponential curve smoothing: Set "3: Slippage method (Exponential) (SlippageExponent)" in the "clutch smoothing method".



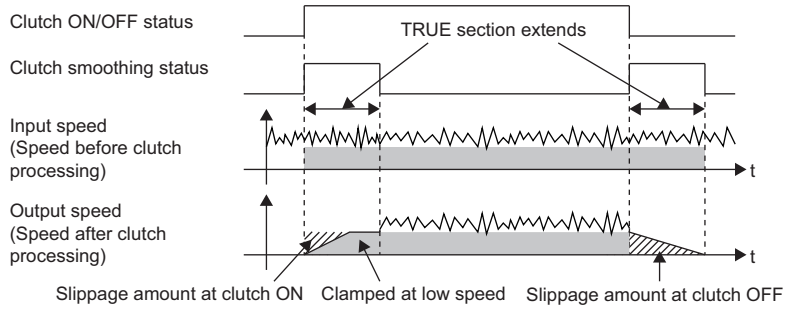
Item	Main shaft clutch	Auxiliary shaft clutch
Clutch ON/OFF status	Main shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.MasterOnOffStatus)	Auxiliary shaft clutch ON/OFF status (AdvOutputName.Md.Clutch.AuxOnOffStatus)
Clutch smoothing status	Main shaft clutch smoothing status (AdvOutputName.Md.Clutch.MasterSmoothingStatus)	Auxiliary shaft clutch smoothing status (AdvOutputName.Md.Clutch.AuxSmoothingStatus)

- Slippage method linear acceleration/deceleration smoothing: Set "4: Slippage method (Linear) (SlippageLinear)" or "5: Slippage method (Linear: Input value follow up) (SlippageLinearFollow)" in the "clutch smoothing method".

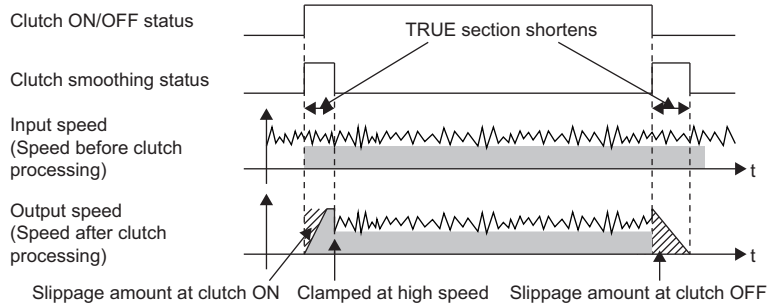
Input speed during smoothing	Smoothing method	
	4: Slippage method (Linear) (SlippageLinear)	5: Slippage method (Linear: Input value follow up) (SlippageLinearFollow)
When input speed is fixed	No difference	
When there is a continuous small fluctuation in the input speed	The smoothing sections change.	The smoothing section is fixed.
When input speed has a large fluctuation	The change in the output speed is small. (The average speed may rise higher than before the start of smoothing)	The output speed changes with the input speed. (When re-accelerating after the input speed drops, a sudden acceleration may occur)

■When input speed is fixed

The operation for "4: Slippage method (Linear) (SlippageLinear)" and "5: Slippage method (Linear: Input value follow up) (SlippageLinearFollow)" is the same.



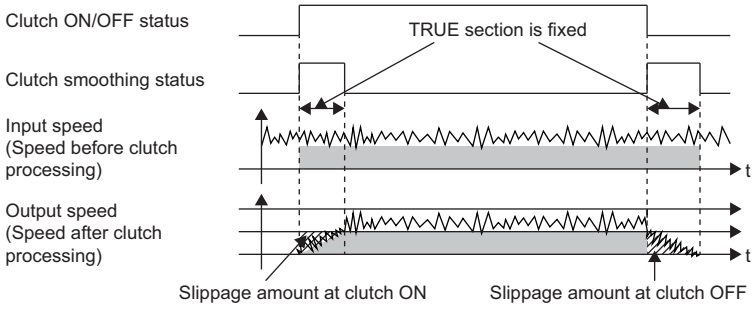
■When there is a continuous small fluctuation in the input speed



- When "4: Slippage method (Linear) (SlippageLinear)" is set

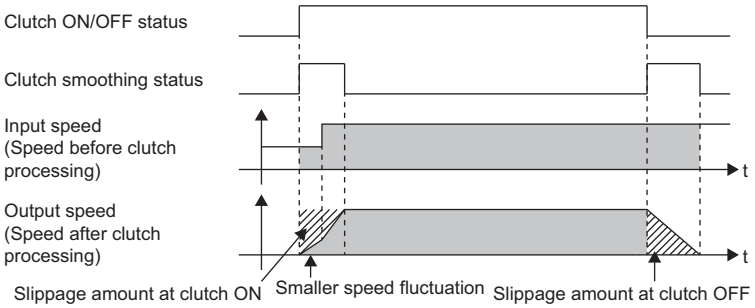
The clutch smoothing status TRUE section changes with the fluctuation of the input speed.

- When the clutch smoothing status TRUE section is extended



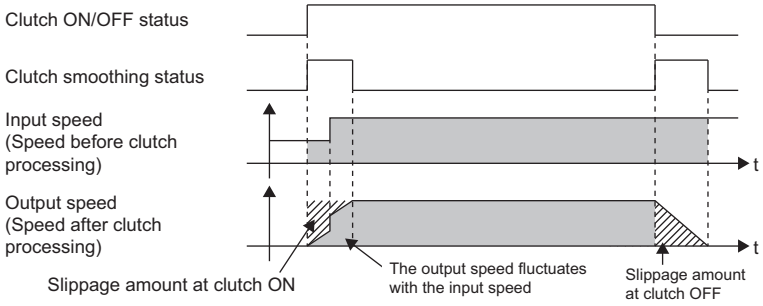
- When the clutch smoothing status TRUE section is shortened

• When "5: Slippage method (Linear: Input value follow up) (SlippageLinearFollow)" is set



The clutch smoothing status TRUE section is fixed.

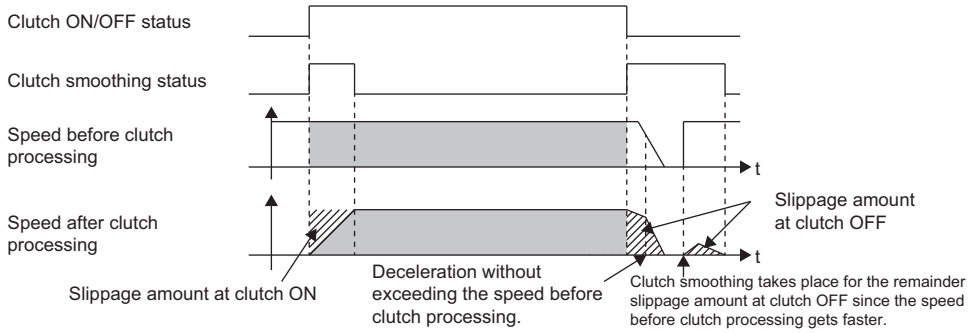
■When input speed has a large fluctuation



• When "4: Slippage method (Linear) (SlippageLinear)" is set

The fluctuation in the output speed is smaller compared to the fluctuation in the input speed. (The average speed may rise higher than before the start of smoothing)

• When "5: Slippage method (Linear: Input value follow up) (SlippageLinearFollow)" is set



The output speed fluctuates with the input speed. (When re-accelerating after the input speed drops, a sudden acceleration may occur)

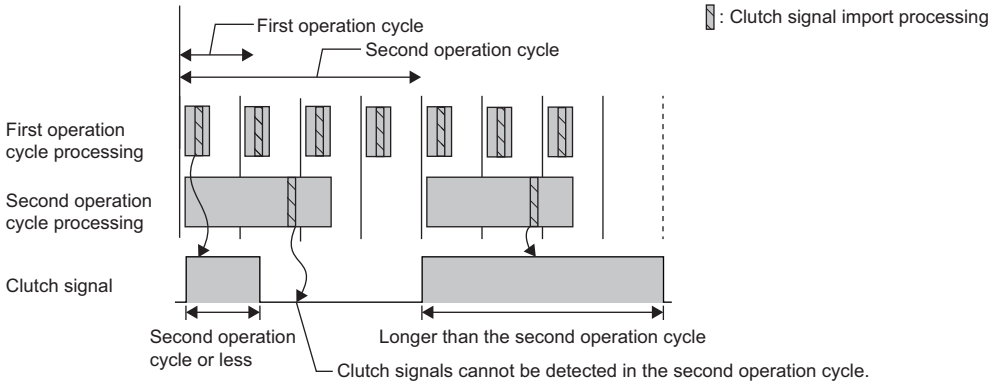
■Operation at input speed deceleration during slippage method smoothing

When the speed before clutch processing decreases, the speed after clutch smoothing is controlled to keep it from exceeding the speed before clutch processing.

If slippage amount remains when the speed before clutch processing becomes "0.0", the smoothing process will continue. When the speed before clutch processing gets faster than the speed after clutch smoothing again, clutch smoothing will be executed for the remainder slippage amount.

Example of clutch use

For an example of clutch use, refer to the following.



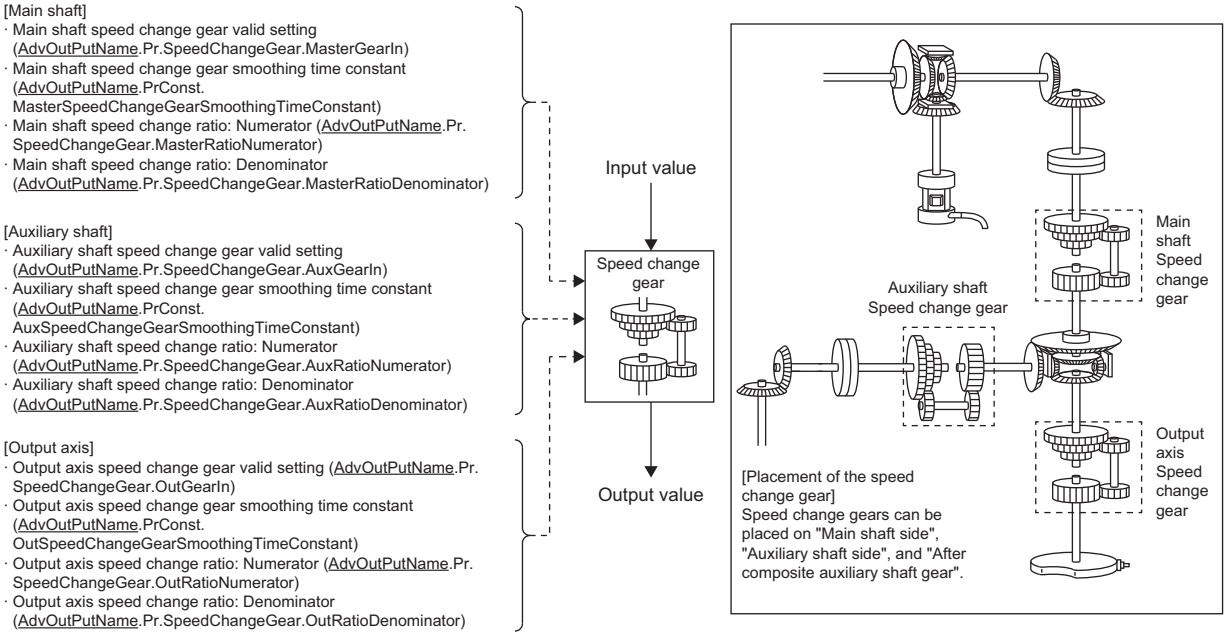
☞ Page 1019 Flying shear

Precautions for the clutch

- When "15: I/O data specification (ClutchSignal)" is specified in the clutch control settings and clutch control is performed using an external signal, be sure to secure at least the following times for TRUE and FALSE of clutch signals. If the times are shorter than the following, signals cannot be detected correctly.

■When external signal high-accuracy input is used
- Device station: Filter time of the device station
- Input module: Input response time of the input module

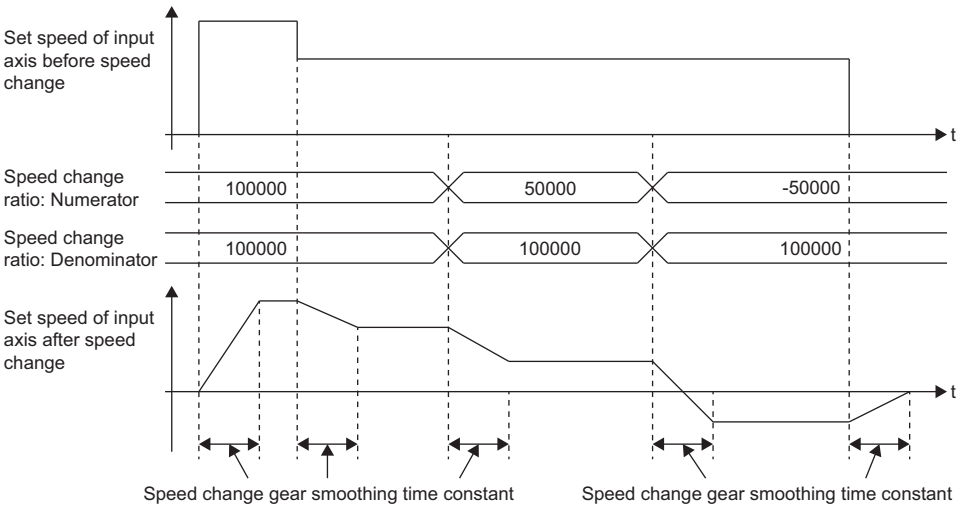
■When not using external signal high-accuracy input
- Refresh cycle of the clutch signal



- When the following data types are specified in the clutch signal settings, match the control operation cycle of the output axis with the operation cycle (network communication cycle) of the referenced module.
  - [OBJ]
  - [VAR] (When a network label is specified)
  - [LINK]

Speed change gear

A speed change gear is used to change the input speed from the main shaft, auxiliary shaft, and composite auxiliary shaft gear during operation. One speed change gear can be set to a main shaft module, an auxiliary shaft module, and an output axis module respectively.



When not using a speed change gear, set "FALSE (Without speed change gear)".

Speed changes from a speed change gear are executed as linear acceleration/deceleration using the time set for the speed change gear smoothing time constant.

Input values for speed change are processed as follows.

$$\text{Input value after conversion} = \text{Input value before conversion} \times \frac{\text{Speed change ratio: Numerator}}{\text{Speed change ratio: Denominator}}$$

Speed change gear parameter of output axis (AdvOutputName.Pr.SpeedChangeGear.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
MasterGearIn	Main shaft speed change gear valid setting	At start	BOOL	• FALSE: Without speed change gear • TRUE: With speed change gear	FALSE
MasterRatioNumerator	Main shaft speed change ratio: Numerator	Operation cycle (FB is starting)	DINT	-2147483648 to 2147483647	1
MasterRatioDenominator	Main shaft speed change ratio: Denominator		DWORD (UDINT)	1 to 2147483647	1
AuxGearIn	Auxiliary shaft speed change gear valid setting	At start	BOOL	• FALSE: Without speed change gear • TRUE: With speed change gear	FALSE
AuxRatioNumerator	Auxiliary shaft speed change ratio: Numerator	Operation cycle (FB is starting)	DINT	-2147483648 to 2147483647	1
AuxRatioDenominator	Auxiliary shaft speed change ratio: Denominator		DWORD (UDINT)	1 to 2147483647	1
OutGearIn	Output axis speed change gear valid setting	At start	BOOL	• FALSE: Without speed change gear • TRUE: With speed change gear	FALSE
OutRatioNumerator	Output axis speed change ratio: Numerator	Operation cycle (FB is starting)	DINT	-2147483648 to 2147483647	1
OutRatioDenominator	Output axis speed change ratio: Denominator		DWORD (UDINT)	1 to 2147483647	1

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Main shaft speed change gear valid setting (AdvOutputName.Pr.SpeedChangeGear.MasterGearIn)/Auxiliary shaft speed change gear valid setting (AdvOutputName.Pr.SpeedChangeGear.AuxGearIn)/Output axis speed change gear valid setting (AdvOutputName.Pr.SpeedChangeGear.OutGearIn)

Set whether to use or not to use a speed change gear for each axis.

Setting value	Description
FALSE (Without speed change gear)	Speed change is not processed, and the input value is transmitted without conversion.
TRUE (With speed change gear)	Speed change is processed for the input value based on the speed change ratio settings.

■Main shaft speed change ratio: Numerator (AdvOutputName.Pr.SpeedChangeGear.MasterRatioNumerator)/Auxiliary shaft speed change ratio: Numerator (AdvOutputName.Pr.SpeedChangeGear.AuxRatioNumerator)/Output axis speed change ratio: Numerator (AdvOutputName.Pr.SpeedChangeGear.OutRatioNumerator)

Set the numerator for the speed change ratio for each axis.

Speed change ratio: Numerator can be changed anytime during synchronous control.

Input values for speed change are processed as follows.

$$\text{Input value after conversion} = \text{Input value before conversion} \times \frac{\text{Speed change ratio: Numerator}}{\text{Speed change ratio: Denominator}}$$

The input speed direction can be reversed by setting a negative value in Speed change ratio: Numerator.

Point

Set a reduced fraction for "Main shaft speed change ratio: Numerator/Main shaft Speed change ratio: Denominator", "Auxiliary shaft speed change ratio: Numerator/Auxiliary shaft Speed change ratio: Denominator", and "Output axis speed change ratio: Numerator/Output axis speed change ratio: Denominator".

■Main shaft speed change ratio: Denominator (AdvOutputName.Pr.SpeedChangeGear.MasterRatioDenominator)/Auxiliary shaft speed change ratio: Denominator (AdvOutputName.Pr.SpeedChangeGear.AuxRatioDenominator)/ Output axis speed change ratio: Denominator (AdvOutputName.Pr.SpeedChangeGear.OutRatioDenominator)

Set the denominator for the speed change ratio for each axis.

Speed change ratio: Denominator can be changed anytime during synchronous control.

Set together with Speed change ratio: Numerator.

Speed change ratio: Denominator is set within the range from "1 to 2147483647".

Output axis parameter constant (AdvOutputName.PrConst.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
MasterSpeedChangeGearSmoothingTimeConstant	Main shaft speed change gear smoothing time constant	At system start	WORD (UINT)	0 to 5000 [ms]	0 [ms]
AuxSpeedChangeGearSmoothingTimeConstant	Auxiliary shaft speed change gear smoothing time constant		WORD (UINT)	0 to 5000 [ms]	0 [ms]
OutSpeedChangeGearSmoothingTimeConstant	Output axis speed change gear smoothing time constant		WORD (UINT)	0 to 5000 [ms]	0 [ms]

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Main shaft speed change gear smoothing time constant (AdvOutputName.PrConst.MasterSpeedChangeGearSmoothingTimeConstant)/Auxiliary shaft speed change gear smoothing time constant (AdvOutputName.PrConst.AuxSpeedChangeGearSmoothingTimeConstant)/Output axis speed change gear smoothing time constant (AdvOutputName.PrConst.OutSpeedChangeGearSmoothingTimeConstant)

Set the averaging time to execute a smoothing process for the speed change when speed change is processed.

The input value transmission is delayed by the set time due to the smoothing process.

Speed is changed directly when "0" is set.

Speed change gear control data of output axis (AdvOutputName.Cd.SpeedChangeGear.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
MasterSmoothingTimeConstant	Main shaft speed change gear smoothing time constant change value	At start	INT	0 to 5000 [ms]	0 [ms]
AuxSmoothingTimeConstant	Auxiliary shaft speed change gear smoothing time constant change value		INT	0 to 5000 [ms]	0 [ms]
OutSmoothingTimeConstant	Output axis speed change gear smoothing time constant change value		INT	0 to 5000 [ms]	0 [ms]

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Main shaft speed change gear smoothing time constant change value (AdvOutputName.Cd.SpeedChangeGear.MasterSmoothingTimeConstant)/Auxiliary shaft speed change gear smoothing time constant change value (AdvOutputName.Cd.SpeedChangeGear.AuxSmoothingTimeConstant)/Output axis speed change gear smoothing time constant change value (AdvOutputName.Cd.SpeedChangeGear.OutSmoothingTimeConstant)

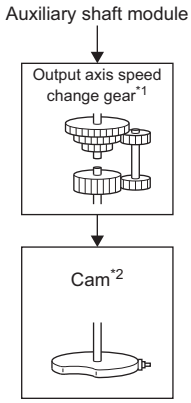
The speed change gear smoothing time constant of each axis is changed.

The setting is imported when MCv_AdvancedSync (Advanced Synchronous Control) is started.

Set as follows.

Setting value	Description
When a negative value is set	No smoothing.
When 0 is set	Smoothing is executed based on the setting value of the speed change gear smoothing time constant*1.
When a positive value is set	Smoothing is executed based on the setting value of the speed change gear smoothing time constant change value*2. Set within the following setting range. Speed change gear smoothing time constant*1 > Speed change gear smoothing time constant change value*2 * If the set value exceeds the range above, Out of Advanced Synchronous Control Variable Range Warning (error code: 0D3FH) occurs, and smoothing is executed based on the setting value of the speed change gear smoothing time constant*1.

*1 The speed change gear smoothing time constant is as follows.

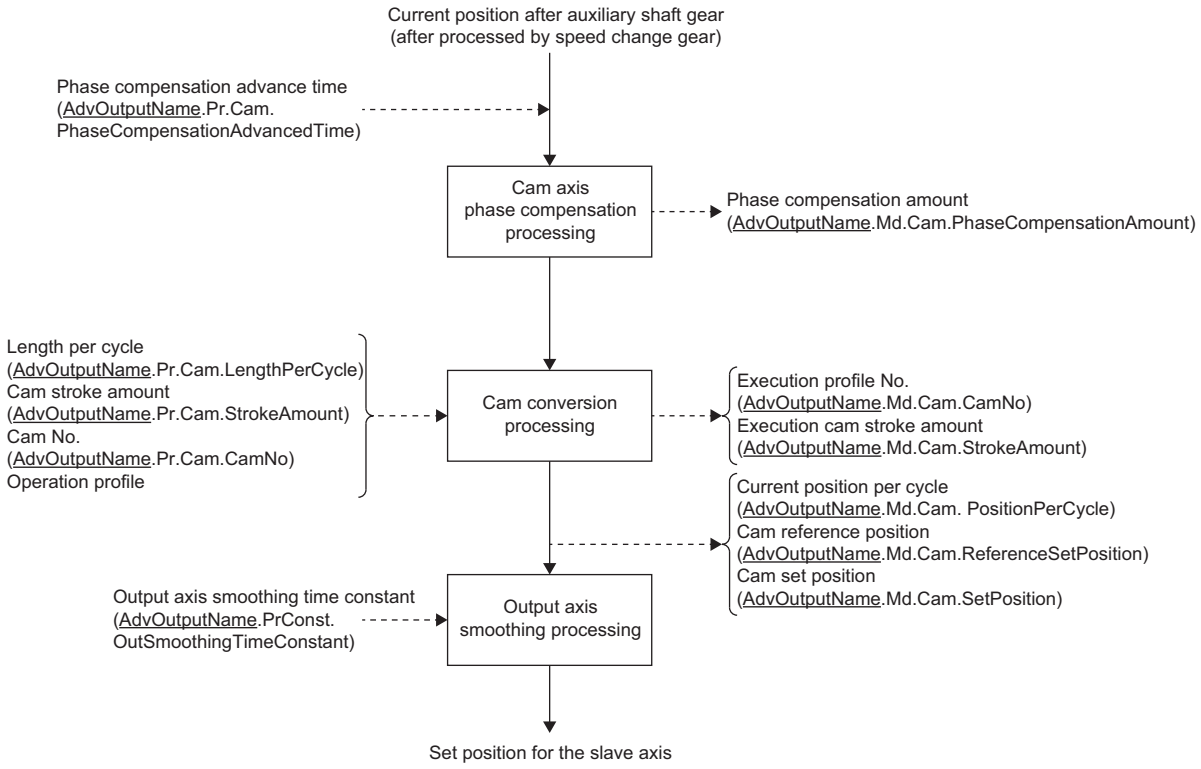


Axis	Variable
Main shaft	Main shaft speed change gear smoothing time constant (AdvOutputName.PrConst.MasterSpeedChangeGearSmoothingTimeConstant)
Auxiliary shaft	Auxiliary shaft speed change gear smoothing time constant (AdvOutputName.PrConst.AuxSpeedChangeGearSmoothingTimeConstant)
Output axis	Output axis speed change gear smoothing time constant (AdvOutputName.PrConst.OutSpeedChangeGearSmoothingTimeConstant)

*2 The speed change gear smoothing time constant change value is as follows.

Axis	Variable
Main shaft	Main shaft speed change gear smoothing time constant change value (AdvOutputName.Cd.SpeedChangeGear.MasterSmoothingTimeConstant)
Auxiliary shaft	Auxiliary shaft speed change gear smoothing time constant change value (AdvOutputName.Cd.SpeedChangeGear.AuxSmoothingTimeConstant)
Output axis	Output axis speed change gear smoothing time constant change value (AdvOutputName.Cd.SpeedChangeGear.OutSmoothingTimeConstant)

Output axis module



For the output axis module, the current position per cycle is calculated based on the input value (the cam set position based on the current position after auxiliary shaft gear after speed change gear processing), which is then converted based on the cam data settings and output to the slave axes as the set position.
In addition, smoothing and phase compensation can be set for the output command.

*1 Speed change gear (☞ Page 960 Speed change gear)

*2 Cam function processing

The parameters and monitor data related to the cam function processing are shown below.

Cam parameter of output axis parameters (AdvOutputName.Pr.Cam.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
LengthPerCycle	Length per cycle	At start/At passing through the 0th point of cam data	LREAL	1.0 to 2147483647.0	1000000.0
StrokeAmount	Cam stroke amount		LREAL	-2147483648.0 to 2147483647.0	1000000.0
CamNo	Cam No.		WORD (UINT)	0 to 60000	0
StartingPoint	Cam starting point		DWORD (UDINT)	0 to 65535	0
LengthPerCycleChange	Length per cycle change setting	At start	INT (MC_LENGTH_PER_CYCLE_CHANGE)	• 0: Invalid (LengthChangeInvalid) • 1: Valid (LengthChangeValid)	0: Invalid (LengthChangeInvalid)
PhaseCompensationAdvancedTime	Phase compensation advance time	At start/Operation cycle (FB is starting)	DINT	-100000000 to 100000000 [μs]	0 [μs]
PhaseCompensationTimeConstant	Phase compensation time constant	At start	WORD (UINT)	0 to 65535 [ms]	10 [ms]

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle)

Set the length per cycle of the cam axis to generate the current position per cycle.

The unit settings are in units of the input axis set as the Master axis (Master) of MCv_AdvancedSync (Advanced Synchronous Control).

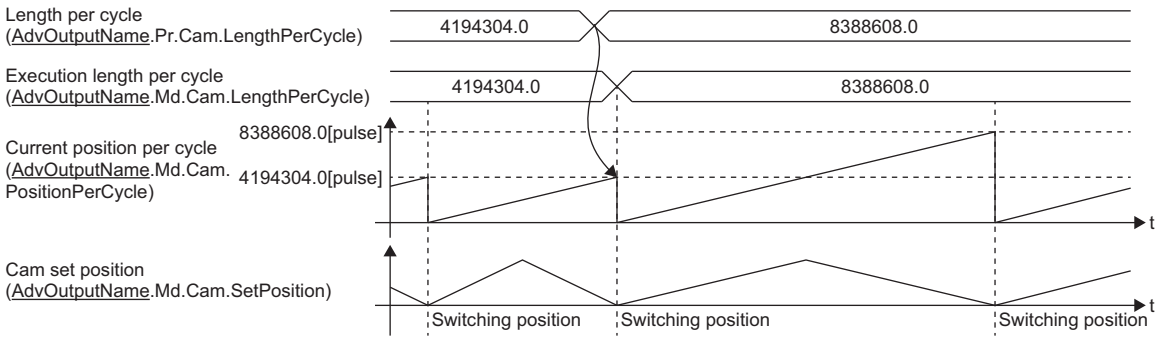
Set a value within the range from "1.0 to 2147483647.0".

The length per cycle can be changed during synchronous control by setting Length per cycle change setting (AdvOutputName.Pr.Cam.LengthPerCycleChange) to "1: Valid (LengthChangeValid)". When the current position per cycle passes through the 0th point of cam data, or is at the 0th point of cam data, the value of the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle) is imported.

When cam data is set, the waveform after the length per cycle is changed varies by the cam data format.

- For cam data (section interpolation)/cam data (spline interpolation): The waveform is shortened/extended so that the one cycle set in the operation profile data is equal to the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle). The maximum value of the stroke amount does not vary with the change of the length per cycle. An example of using cam data (section interpolation) and changing the length per cycle during synchronous control is shown below.

Ex.



A setting example of cam data (section interpolation)

· Length per cycle: 4194304.0

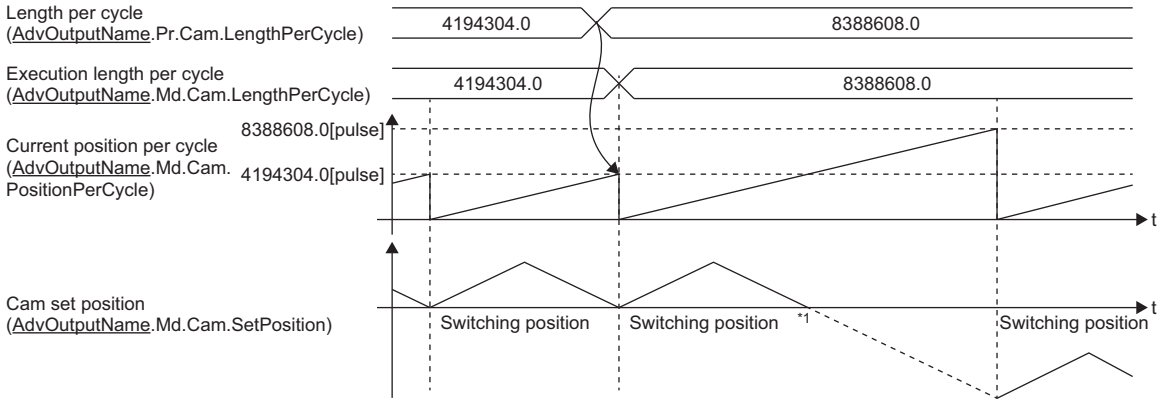
· Cam stroke amount: ±4194304.0

· Stroke ratio data

Section No.	Start point [pulse]	End point [pulse]	Stroke [%]
1	0.0	2097152.0	100.0
2	297152.0	4194304.0	0.0

- For cam data (linear interpolation): When the input value of the final coordinates is less than the length per cycle, it is controlled using a line segment calculated from the two coordinates nearest to the final coordinates. An example of using cam data (linear interpolation) and changing the length per cycle to a value that exceeds the input value of cam data final coordinates during synchronous control is shown below.

Ex.



A setting example of cam data (linear interpolation)

· Length per cycle: 4194304.0

· Cam stroke amount: ±4194304.0

· Coordinate data

Point	Input value	Cam set position
1	0.0	0.0
2	2097152.0	4194304.0
3	4194304.0	0.0

*1 Because the coordinates where "input value = length per cycle" do not exist, control is performed using a line segment calculated from the two coordinates nearest to the final coordinates.

Point

- Do not set digits after the decimal point. If set, the errors will be accumulated every time the current position per cycle permissible value is exceeded.
- When cam data change and length per cycle change are executed simultaneously, the length per cycle will not be changed if cam data change fails.

■Cam stroke amount (AdvOutputName.Pr.Cam.StrokeAmount)

When the Interpolation method specification (Interpolate) of the operation profile data is set to "1: Section interpolation" or "2: Spline interpolation", or the data format is set to "Rotary cutter", set the cam stroke amount corresponding to a 100% stroke ratio in the position command unit of the axis set in the output axis Axis information (AdvOutputName.Axis).

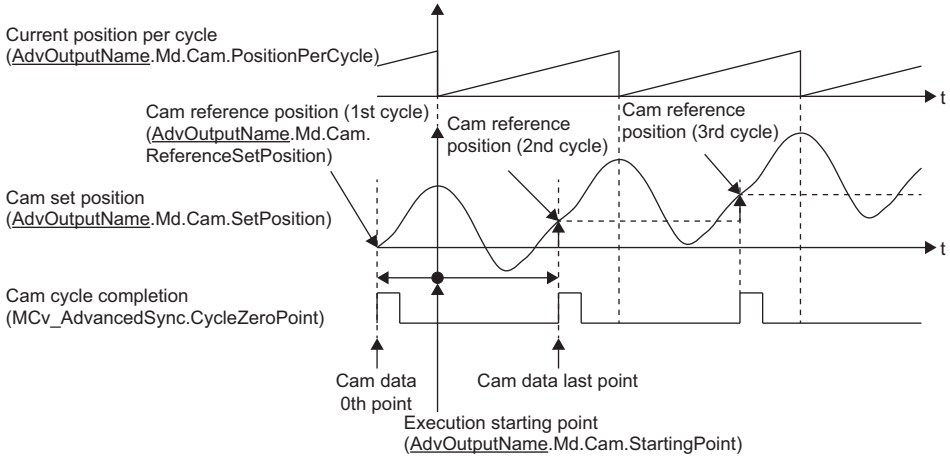
The cam stroke amount can be changed during synchronous control.

The value of Cam stroke amount (AdvOutputName.Pr.Cam.StrokeAmount) is imported when the current position per cycle passes through the 0th point of cam data, or is at the 0th point.

Point

Do not set digits after the decimal point. If set, the errors will be accumulated every time the current position per cycle permissible value is exceeded.

■Cam No. (AdvOutputName.Pr.Cam.CamNo)



Set the cam No. used for cam control.

■Cam starting point (AdvOutputName.Pr.Cam.StartingPoint)

Set the starting point of cam data in resolutions.

This setting is valid only when the Interpolation method specification (Interpolate) of the operation profile data is set to "1: Section interpolation" or "2: Spline interpolation", or the data format is set to "Rotary cutter".

The initial value of the Cam starting point (AdvOutputName.Pr.Cam.StartingPoint) is "0". (The cam axis is controlled with cam data starting from the 0th point (stroke ratio 0%).) When a value other than "0" is set, cam control is started from a stroke ratio other than 0%.

Point

- The cam reference position is the cam set position at the 0th point of cam data.
- The Cam starting point (AdvOutputName.Pr.Cam.StartingPoint) is imported when cam data switches. When a value exceeding the cam data resolution is set in the Cam starting point (AdvOutputName.Pr.Cam.StartingPoint), control is performed using the cam data and cam starting point before the change.

■Length per cycle change setting (AdvOutputName.Pr.Cam.LengthPerCycleChange)

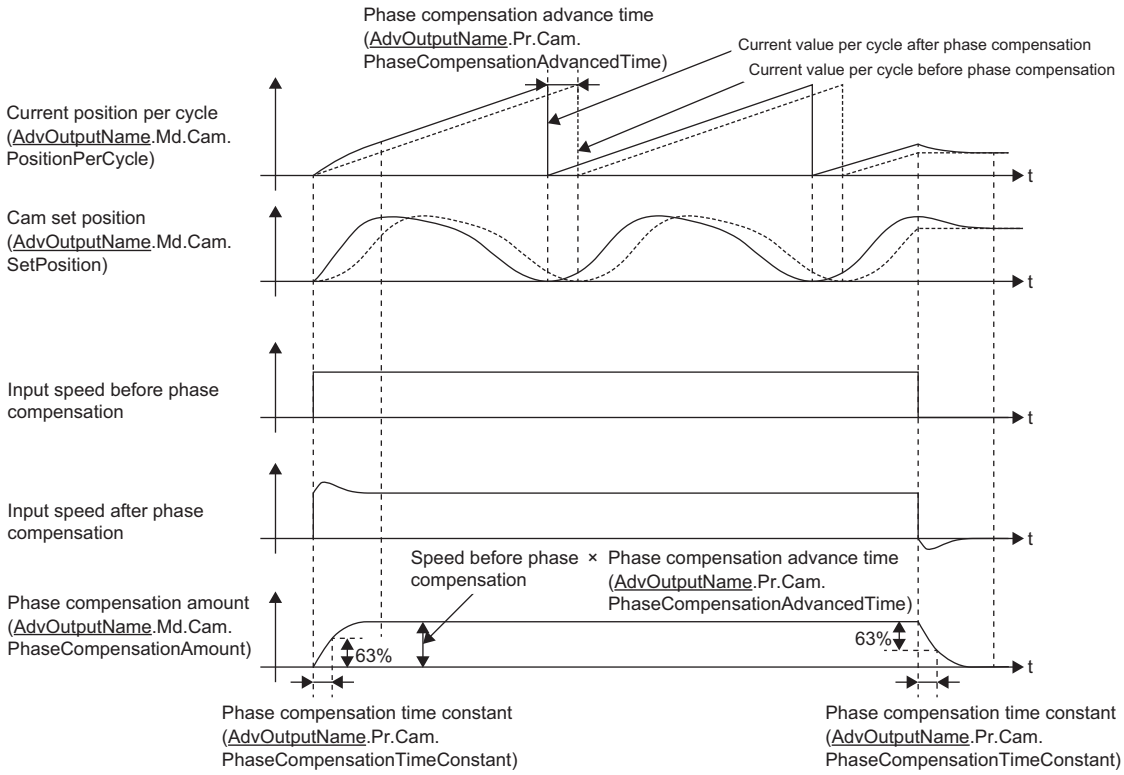
Set this when changing the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle) during synchronous control.

This can change the length per cycle in cam No.0 (linear cam), cam data (linear interpolation), or cam data (section interpolation). However, this cannot change the length per cycle in cam data (section interpolation) that uses cam data with starting point other than 0.

Setting value	Description
0: Invalid (LengthChangeInvalid)	Cannot change the length per cycle during synchronous control.
1: Valid (LengthChangeValid)	Imports the value of the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle) when the current position per cycle passes through the 0th point of cam data, or is at the 0th point.

■Phase compensation advance time (AdvOutputName.Pr.Cam.PhaseCompensationAdvancedTime)

Set the time to advance or delay the phase of the current position per cycle in the cam control.



Setting value	Description
1 to 100000000 [μs]	Advance the phase according to the setting time.
0 [μs]	Do not execute phase compensation.
-100000000 to 1 [μs]	Delay the phase according to the setting time.

If the setting time is too long, the system experiences overshoot or undershoot at acceleration/deceleration of the input movement amount to the output axis. In this case, set a longer time to reflect the phase compensation amount in the Phase compensation time constant (AdvOutputName.Pr.Cam.PhaseCompensationTimeConstant).

■Phase compensation time constant (AdvOutputName.Pr.Cam.PhaseCompensationTimeConstant)

Set the time constant for reflecting the phase compensation amount for the first order delay.

63% of the phase compensation amount is reflected in the specified time constant.

Cam monitor of output axis monitor data (AdvOutputName.Md.Cam.)

Variable name	Name	Import*1	Data type*1	Monitor value
MasterCompositeGearSetPosition	Current position after composite main shaft gear	Operation cycle (FB is starting)	LREAL	-10000000000.0 to 10000000000.0
MasterGearPositionPerCycle	Current position per cycle after main shaft gear		LREAL	0.0 to (length per cycle - 0.00001)
AuxGearPositionPerCycle	Current position per cycle after auxiliary shaft gear		LREAL	0.0 to (length per cycle - 0.00001)
PhaseCompensationAmount	Phase compensation amount		LREAL	-2147483648.0 to 2147483647.0
PositionPerCycle	Current position per cycle		LREAL	0.0 to (length per cycle - 0.00001)
ReferenceSetPosition	Cam reference position		LREAL	-10000000000.0 to 10000000000.0
SetPosition	Cam set position		LREAL	-10000000000.0 to 10000000000.0
CamNo	Execution profile No.		WORD (UINT)	0 to 60000
StrokeAmount	Execution cam stroke amount		LREAL	-2147483648.0 to 2147483647.0
LengthPerCycle	Execution length per cycle		LREAL	1.0 to 2147483647.0
StartingPoint	Execution cam starting point		DWORD (UDINT)	0 to 65535

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Current position after composite main shaft gear (AdvOutputName.Md.Cam.MasterCompositeGearSetPosition)

The current position after the composite main shaft gear combines the values from the main shaft and the sub input axis is stored as an accumulative value.

The unit settings are in units of the input axis set as the Master axis (Master) of MCv_AdvancedSync (Advanced Synchronous Control).

The Current position after composite main shaft gear (AdvOutputName.Md.Cam.MasterCompositeGearSetPosition) is backed up. For details, refer to the following.

☞ Page 990 Synchronous Control Initial Position

■Current position per cycle after main shaft gear (AdvOutputName.Md.Cam.MasterGearPositionPerCycle)

The input movement amount after the main shaft gear is stored within the range from "0.0 to (length per cycle - 0.00001)".

The unit settings are in units of the input axis set to Master axis (Master) of MCv_AdvancedSync (Advanced Synchronous Control).

The Current position per cycle after main shaft gear (AdvOutputName.Md.Cam.MasterGearPositionPerCycle) is backed up. For details, refer to the following.

☞ Page 990 Synchronous Control Initial Position

■Current position per cycle after auxiliary shaft gear (AdvOutputName.Md.Cam.AuxGearPositionPerCycle)

The input movement amount after the auxiliary shaft gear is stored within the range from "0.0 to (length per cycle - 0.00001)".

The unit settings are in units of the input axis set to Master axis (Master) of MCv_AdvancedSync (Advanced Synchronous Control).

The Current position per cycle after auxiliary shaft gear (AdvOutputName.Md.Cam.AuxGearPositionPerCycle) is backed up. For details, refer to the following.

☞ Page 990 Synchronous Control Initial Position

■Phase compensation amount (AdvOutputName.Md.Cam.PhaseCompensationAmount)

The phase compensation amount after smoothing processing with the Phase compensation time constant (AdvOutputName.Pr.Cam.PhaseCompensationTimeConstant) is stored.

The unit settings of phase compensation amount are in units of the input axis set as the Master axis (Master) of MCv_AdvancedSync (Advanced Synchronous Control).

■Current position per cycle (AdvOutputName.Md.Cam.PositionPerCycle)

The current position per cycle is stored within the range from "0.0 to (length per cycle - 0.00001)".
The current position after phase compensation processing can be monitored. The unit settings are in units of the input axis set as the Master axis (Master) of MCv_AdvancedSync (Advanced Synchronous Control).
The Current position per cycle (AdvOutputName.Md.Cam.PositionPerCycle) is backed up. For details, refer to the following.
☞ Page 990 Synchronous Control Initial Position

■Cam reference position (AdvOutputName.Md.Cam.ReferenceSetPosition)

The set position is stored as the cam reference position of the cam operation. The unit settings are in position command units of the axis set in the output axis Axis information (AdvOutputName.Axis).
The cam reference position range is the positioning range of the axis assigned as the output axis.
The Cam reference position (AdvOutputName.Md.Cam.ReferenceSetPosition) is backed up. For details, refer to the following.
☞ Page 990 Synchronous Control Initial Position

■Cam set position (AdvOutputName.Md.Cam.SetPosition)

- The set position of the cam axis is stored. The unit settings are in position command units of the axis set in the output axis Axis information (AdvOutputName.Axis).
- When the Output axis smoothing time constant (AdvOutputName.PrConst.SmoothingTimeConstant) is "0" during the execution of synchronous control, the value of the Set position (AxisName.Md.SetPosition) of the axis set in the output axis Axis information (AdvOutputName.Axis) is equal to the value of the Cam set position (AdvOutputName.Md.Cam.SetPosition).
- When the Output axis smoothing time constant (AdvOutputName.PrConst.SmoothingTimeConstant) is other than "0" during the execution of synchronous control, the value of the Set position (AxisName.Md.SetPosition) of the axis set in the output axis Axis information (AdvOutputName.Axis) is equal to the value of the Cam set position (AdvOutputName.Md.Cam.SetPosition) after the smoothing is completed.
- The Cam set position (AdvOutputName.Md.Cam.SetPosition) is backed up. For details, refer to the following.
  ☞ Page 990 Synchronous Control Initial Position

■Execution profile No. (AdvOutputName.Md.Cam.CamNo)

The executing cam No. is stored.
When the Cam No. (AdvOutputName.Pr.Cam.CamNo) is changed during synchronous control, this is updated when the controlling cam No. switches.
The same value of the Execution profile No. (AdvOutputName.Md.Cam.CamNo) is stored to the Execution profile ID (AxisName.Md.ProfileID).

■Execution cam stroke amount (AdvOutputName.Md.Cam.StrokeAmount)

The executing cam stroke amount is stored.
When the Cam stroke amount (AdvOutputName.Pr.Cam.StrokeAmount) is changed during synchronous control, this is updated when the controlling cam stroke amount switches.

■Execution length per cycle (AdvOutputName.Md.Cam.LengthPerCycle)

The executing cam length per cycle is stored.
When the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle) is changed during synchronous control, this is updated when the controlling length per cycle switches.

■Execution cam starting point (AdvOutputName.Md.Cam.StartingPoint)

The executing cam starting point is stored. When the Cam starting point (AdvOutputName.Pr.Cam.StartingPoint) is changed during synchronous control, this is updated when the cam switches.

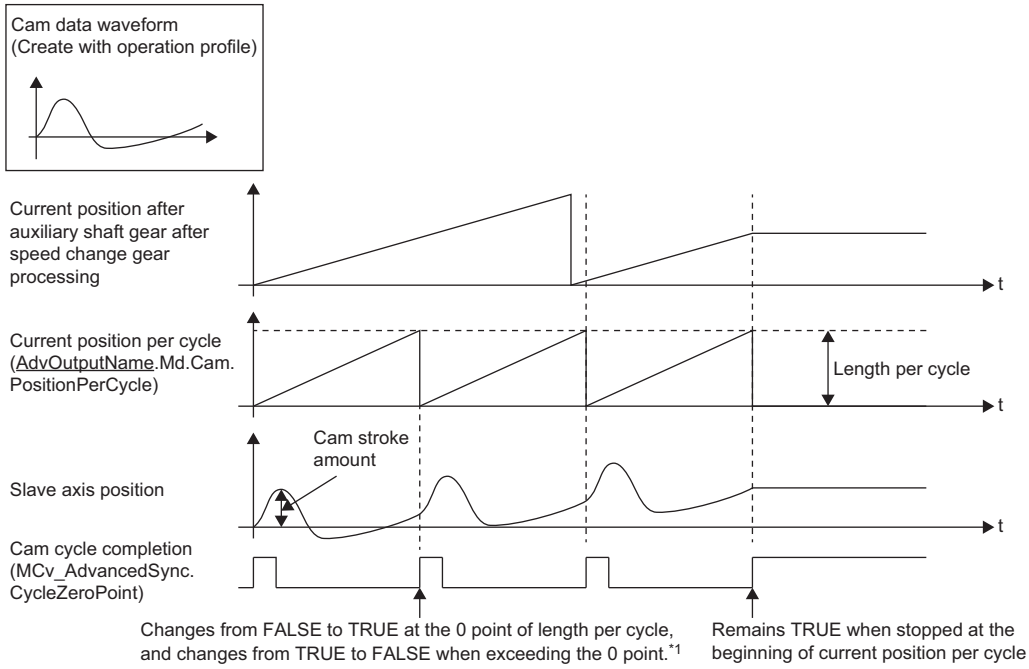
Cam control data of output axis parameters (AdvOutputName.Cd.Cam.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
OutSmoothingTimeConstant	Output axis smoothing time constant change value	At start	INT	0 to 5000 [ms]	0

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Output axis smoothing time constant change value (AdvOutputName.Cd.Cam.OutSmoothingTimeConstant)

The output axis smoothing time constant is changed. The setting is imported when MCv_AdvancedSync (Advanced Synchronous Control) is started.



Setting value	Description
When a negative value is set	No smoothing.
When 0 is set	Smoothing is executed based on the setting value of the Output axis smoothing time constant (AdvOutputName.PrConst.SmoothingTimeConstant).
When a positive value is set	Smoothing is executed based on the setting value of the Output axis smoothing time constant change value (AdvOutputName.Cd.Cam.OutSmoothingTimeConstant). Set within the following setting range. Output axis smoothing time constant (AdvOutputName.PrConst.SmoothingTimeConstant) > Output axis smoothing time constant change value (AdvOutputName.Cd.Cam.OutSmoothingTimeConstant) * If the set value exceeds the range above, Out of Advanced Synchronous Control Variable Range Warning (error code: 0D3FH) occurs, and smoothing is executed based on the setting value of the Output axis smoothing time constant (AdvOutputName.PrConst.SmoothingTimeConstant).

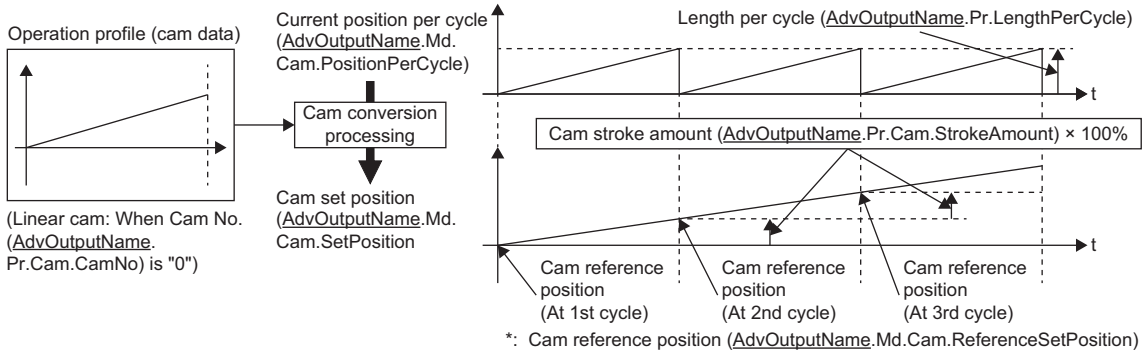
Cam function

Cam data sets the cam ID to Cam No. (AdvOutputName.Pr.Cam.CamNo).

To use the operation profile data, set auto expand in the expand setting beforehand, or use MC_CamTableSelect (Cam Table Selection) to open the data in the open area.

Timing chart during cam operation

*1 When a value other than 0 is set to the cam data starting point, it becomes TRUE at the set cam data starting point.

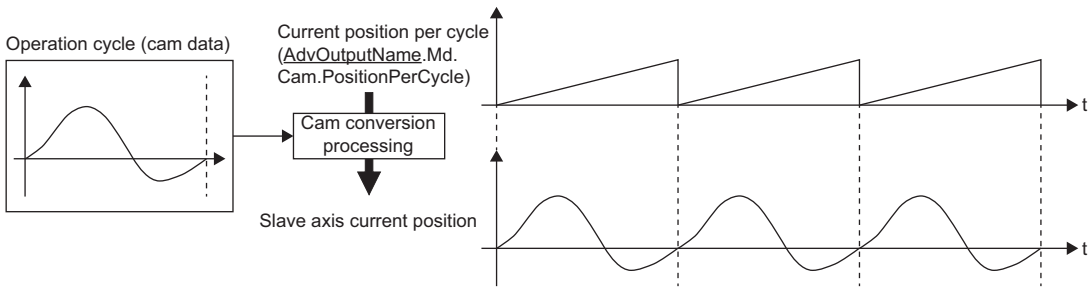


Cam data operation

Cam data for advanced synchronous control performs the following operations.

■Linear cam

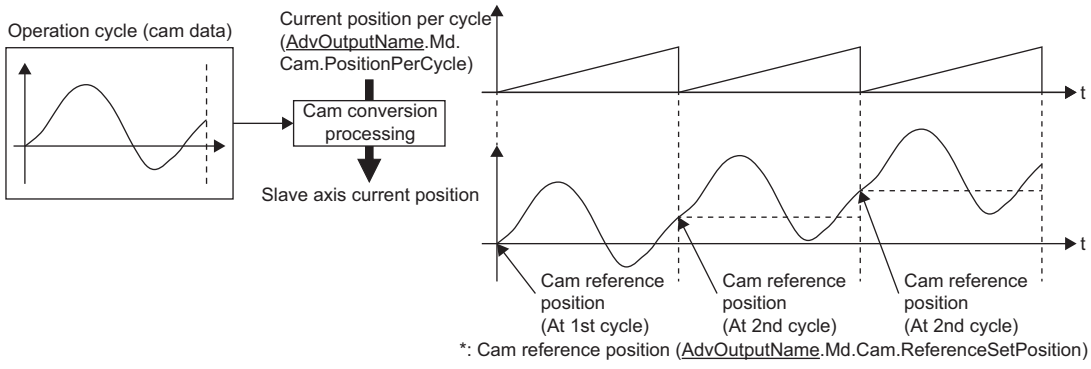
A linear operation with one cycle as a 100% stroke ratio.



A linear cam operation occurs when Cam No. (AdvOutputName.Pr.Cam.CamNo) is set to "0".

■Two-way cam

A reciprocating cam operation with a constant cam stroke range.

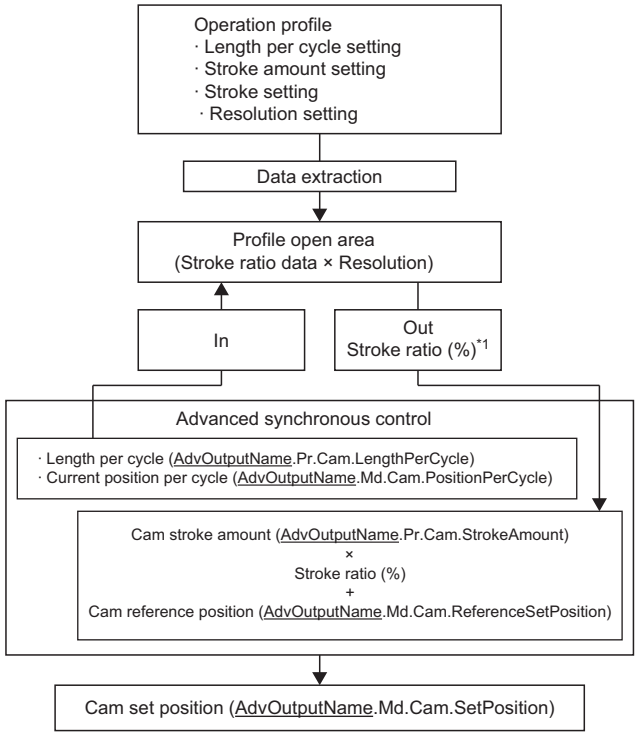


A two-way cam operation occurs when "start point = end point" for the cam data created with the operation profile data.

■Feed cam

A cam operation where the cam reference position is updated every cycle.

A feed cam operation occurs when "start point ≠ end point" for the cam data created with the operation profile data.

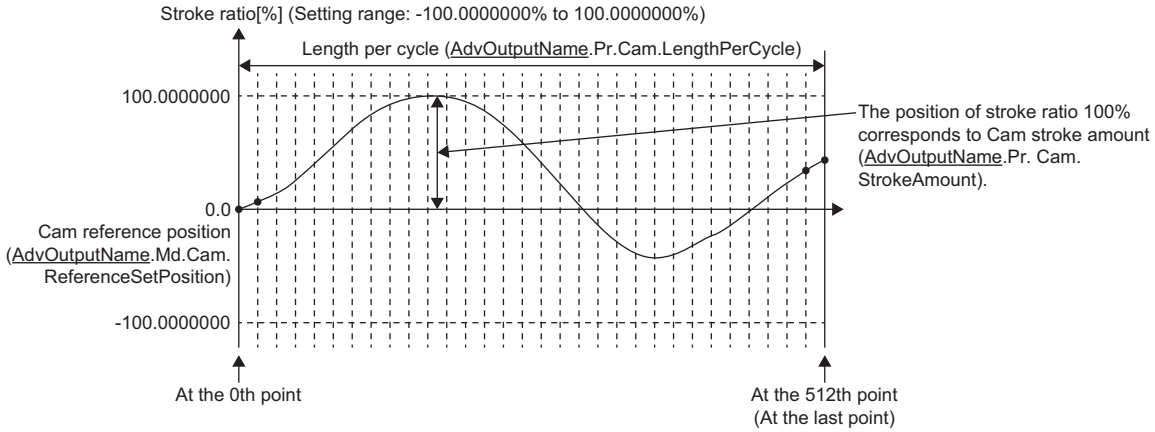


Cam control by operation profile data

When using cam control in advanced synchronous control, the data transmitted to the open area varies depending on the interpolation method specification of the operation profile data and the data format.

■When the Interpolation method specification (Interpolate) of the operation profile data is "1: Section interpolation" or "2: Spline interpolation", or the data format is set to "Rotary cutter"

The cam data is defined in equal divisions for one cam cycle based on the cam resolution, and configured with stroke ratio data from points within the cam resolution.



When this setting is configured, the relationship between the operation profile data and advanced synchronous control is as follows.

*1 The stroke ratio is calculated according to Current position per cycle (AdvOutputName.Md.Cam.PositionPerCycle) using the stroke ratio and resolution of the open area and Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle).

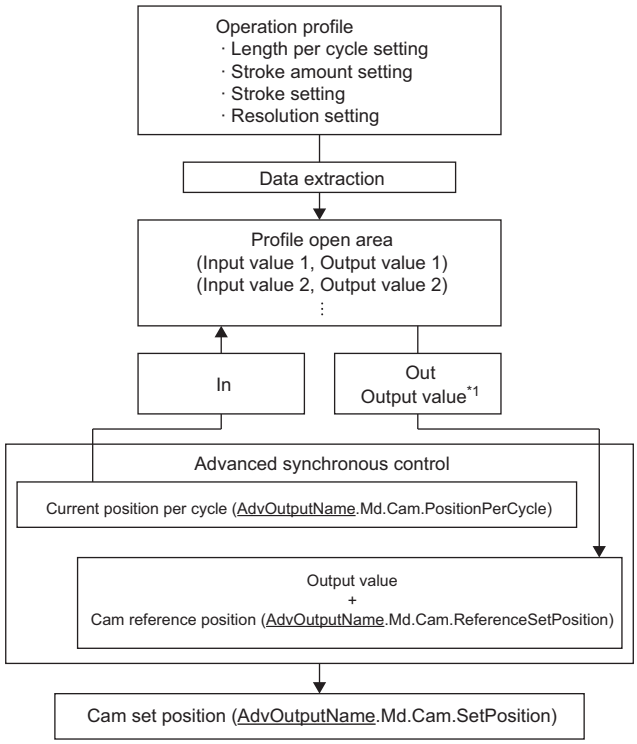
Ex.

When the cam resolution is 512

• Timing for reflecting cam control data

If the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle) or the Cam No. (AdvOutputName.Pr.Cam.CamNo), or the Cam stroke amount (AdvOutputName.Pr.Cam.StrokeAmount) is changed, the new value is imported and reflected when the Current position per cycle (AdvOutputName.Pr.Cam.PositionPerCycle) passes through the 0th point of cam data, or is at the 0th point.

For "Cam starting point = 0", the cam reference position is updated when the current position per cycle exceeds the permissible value.

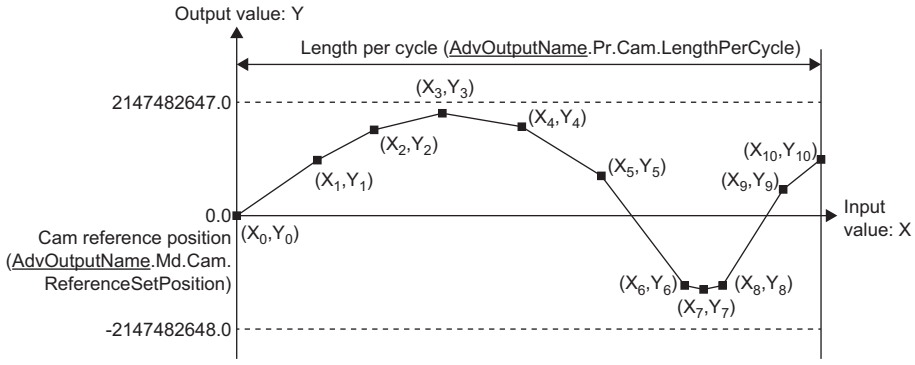


For "Cam starting point ≠ 0", the cam reference position is updated when the current position per cycle passes through the 0th point of cam data.

■When the Interpolation method specification (Interpolate) of the operation profile data is set to "0: Linear interpolation"

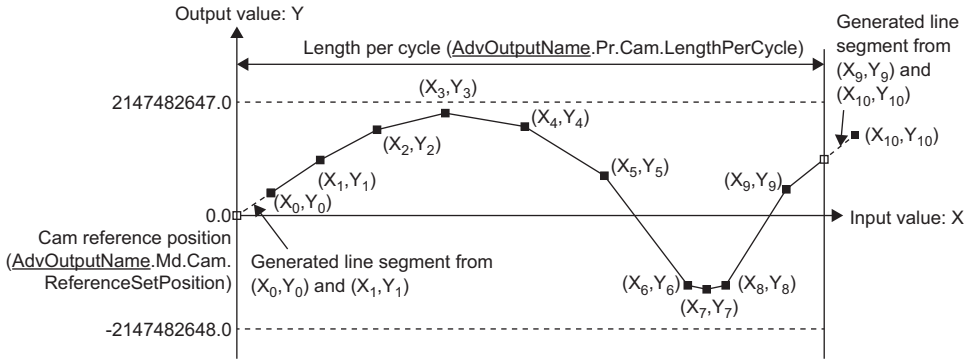
The cam data defines a cam curve in two or more points of coordinate data for one cycle. The coordinate data is expressed as "(input value, output value)", with "input value = axis current position per cycle", and "output value = stroke amount from cam reference position".

The Cam stroke amount (AdvOutputName.Pr.Cam.StrokeAmount) of output axis parameter is ignored, and the output value of the coordinate data becomes cam stroke amount.



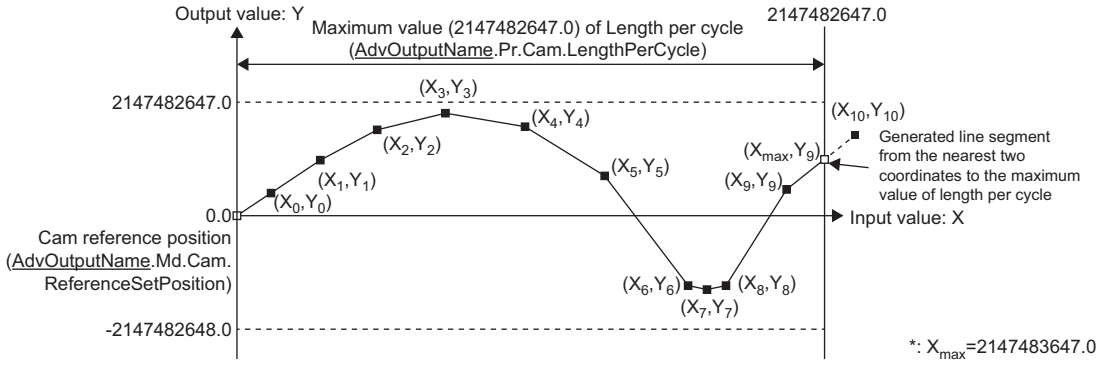
When this setting is configured, the relationship between the operation profile data and advanced synchronous control is as follows.

*1 The output value corresponding to the Current position per cycle (AdvOutputName.Md.Cam.PositionPerCycle) is calculated based on the input value and output value of the open area. In addition, the result of the calculation is truncated after the 5th decimal place.



Ex.

When the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle) is equivalent to the setting value of the length per cycle setting in the operation profile data



Ex.

When "input value = 0" and "input value = length per cycle" coordinates do not exist in the coordinate data, control is performed using a line segment calculated from the nearest two coordinates.

Ex.

If the input value exceeds the maximum value (2147483647.0) of the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle), the control is performed using a line segment calculated from the two coordinates nearest to the maximum value of the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle). In this case, the input value X at the last point of the coordinates is equivalent to the maximum value of the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle).

- Timing for reflecting cam control data

If the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle) or the Cam No. (AdvOutputName.Pr.Cam.CamNo) is changed during synchronous control, the new value is imported and reflected when the Current position per cycle (AdvOutputName.Pr.Cam.PositionPerCycle) passes through "0.0", or is at the position of "0.0".

The cam reference position is updated when the current position per cycle passes through "0.0".

■Setting list for using the operation profile data in advanced synchronous control

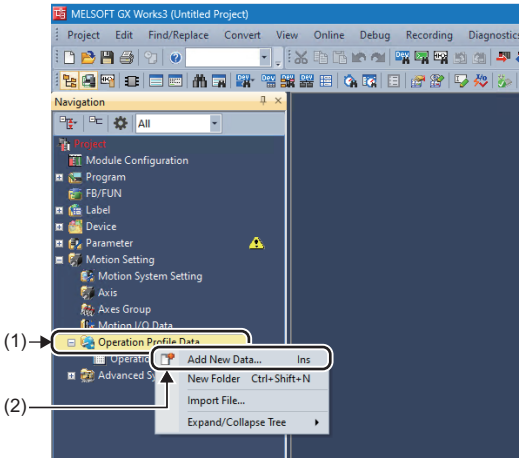
The settings for using the operation profile data in advanced synchronous control are shown below.

When specifying setting values, set the specified value, or a value within the range. When a specified value or a value within the range is not set, an error or an unintended operation may occur.

Setting item[*1]		Interpolation method specification (Interpolate)	
		1: Section Interpolation/2: Spline Interpolation	0: Linear Interpolation
Periodic (Options (Options): Bit 0)		Set to "1: Periodic". When set to other than "1: Periodic", Operation Profile Data Settings Incorrect Under Advanced Synchronous Control (error code: 1B2AH) will occur at FB start.	
Master axis (input) absolute coordinate (Options (Options): Bit 1)		Set to "0: Relative coordinate". When set to other than "0: Relative coordinate", Operation Profile Data Settings Incorrect Under Advanced Synchronous Control (error code: 1B2AH) will occur at FB start.	
Slave axis (output) absolute coordinate (Options (Options): Bit 2)		Set to "0: Relative coordinate". When set to other than "0: Relative coordinate", Operation Profile Data Settings Incorrect Under Advanced Synchronous Control (error code: 1B2AH) will occur at FB start.	
Profile ID		Set to any value within the range of 1 to 60000.	
Interpolation method specification (Interpolate)		Set to "1: Section Interpolation" or "2: Spline Interpolation".	Set to "0: Linear Interpolation".
Resolution/coordinate number (Resolution)		Set the number of divisions for a cam curve for one cycle.	Set the number of coordinate points in a cam curve for one cycle. The 0th point is included in the number of coordinate points.
Input unit character string (InputUnitString)		Set the unit of the axis to be set as the main shaft.	
Output unit character string (OutputUnitString)		Set the unit of the stroke amount.	Set the unit of the axis to be set as the output axis.
Start point (StartPoint)		Set to "0.0". When set to other than "0.0", Operation Profile Data Settings Incorrect Under Advanced Synchronous Control (error code: 1B2AH) will occur at FB start. When setting the cam data starting point in advanced synchronous control, set the Cam starting point (AdvOutputName.Pr.Cam.StartingPoint) of the output axis parameters.	
Initial stroke amount (StartStroke)		Set to "0.0". When set to other than "0.0", Operation Profile Data Settings Incorrect Under Advanced Synchronous Control (error code: 1B2AH) will occur at FB start.	
Initial velocity (StartVelocity)		Set this item when "1: Section Interpolation" is used. Set the velocity at the start point/end point. Use when the Cam curve type (CurveType) is set to "12: 5th curve (Adj.) (FifthCurve_SpeedDesignation)".	It is not used in the coordinate data format.
Initial acceleration (StartAcceleration)		Set this item when "1: Section Interpolation" is used. Set the acceleration at the start point/end point. Use when the Cam curve type (CurveType) is set to "12: 5th curve (Adj.) (FifthCurve_SpeedDesignation)".	
I/O data	Input value	Do not set this item when "1: Section Interpolation" or "2: Spline Interpolation" is used.	• Set the input value at each point No. • Set the input value within the range of "0.0 to 2147483647.0". When an input value exceeding "2147483647.0" is set, the control is performed using a line segment calculated from the two coordinates nearest to the maximum value of the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle).
	Output value		• Set the output value corresponding with the input value at each point No. • Set the output value within the range of "-2147483648.0 to 2147483647.0". If a value outside the range is set, Operation Profile Data Settings Incorrect Under Advanced Synchronous Control (error code: 1B2AH) will occur.

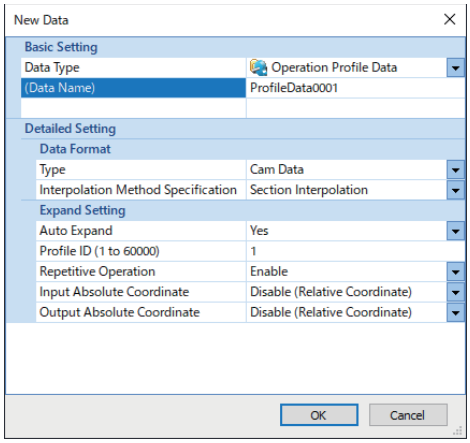
Setting item*1		Interpolation method specification (Interpolate)	
		1: Section Interpolation/2: Spline Interpolation	0: Linear Interpolation
Parameter	Cam curve type (CurveType)	Set to any type to match the cam data to be created.	It is not used in the coordinate data format.
	End point (EndPoint)	Set the end point of each section.	
	Stroke (Stroke)	Set the stroke of each section.	
	Curve applicable range (RangeP1/RangeP2)	Set the curve applicable range (start point: P1, end point: P2) for the cam curve. (0.0 to 1.0) Set within the range of "P1 < P2". However, for "P1 = P2 = 0", "P1 = 0" and "P2 = 1" are applied. For curve applicable range, the setting can be omitted.	
	Acceleration/deceleration range compensation (RangeL1)	Set the acceleration/deceleration range (L1, L2) of the cam curve. (0.0001 < L1, L2 < 1.0000) The range that can be set differs depending on the cam curve. For "L1 = L2 = 0.0000", the default value for each cam curve is applied. On the curve that does not use L1 or L2, the setting value is ignored.	
	End point velocity (EndVelocity)	Set the end point velocity of the cam curve.	
	End point acceleration (EndAcceleration)	Set the end point acceleration of the cam curve.	
Length per cycle (CycleLength)		Although the setting is ignored in advanced synchronous control, set the same value to the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle). The setting value of the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle) is used for actual control.	
Minimum value per cycle (CycleMin)		Do not set this item when "1: Section Interpolation" or "2: Spline Interpolation" is used.	Set to "0.0". Set this item when the Interpolation method specification (Interpolate) is set to "0: Linear Interpolation".
Maximum value per cycle (CycleMax)			Set the setting value of Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle). Set this item when the Interpolation method specification (Interpolate) is set to "0: Linear Interpolation".
Time per cycle (CycleTime)		Set the time that is required for one cycle. Use when the cam curve type (CurveType) is set to "12: 5th curve (Adj.) (FifthCurve_SpeedDesignation)".	Not used in "0: Linear Interpolation".
Stroke amount (Stroke)		When the unit is "%", the setting is ignored. When the unit is other than "%", set to 100 % stroke amount. ■Example: If the stroke amount is set to "200.0" when the unit is "mm", the cam data will have "200.0" as the 100% stroke ratio.	Set to a value equal to or more than the maximum value of the output value in the I/O data.
Number of sections (NumberOfSections)		Set to a value within the following ranges depending on the interpolation method specification (Interpolate). ■"1: Section Interpolation" 1 to 360 ■"2: Spline Interpolation" 3 to 360	It is not used in the coordinate data format.

*1 The variable inside the ( ) is the member name of the PROFILE_CAM_DATA data type, or the PROFILE_CAM_ELEMENT data type.



When the data format is "rotary cutter", refer to the following.

☞ Page 837 Rotary cutter

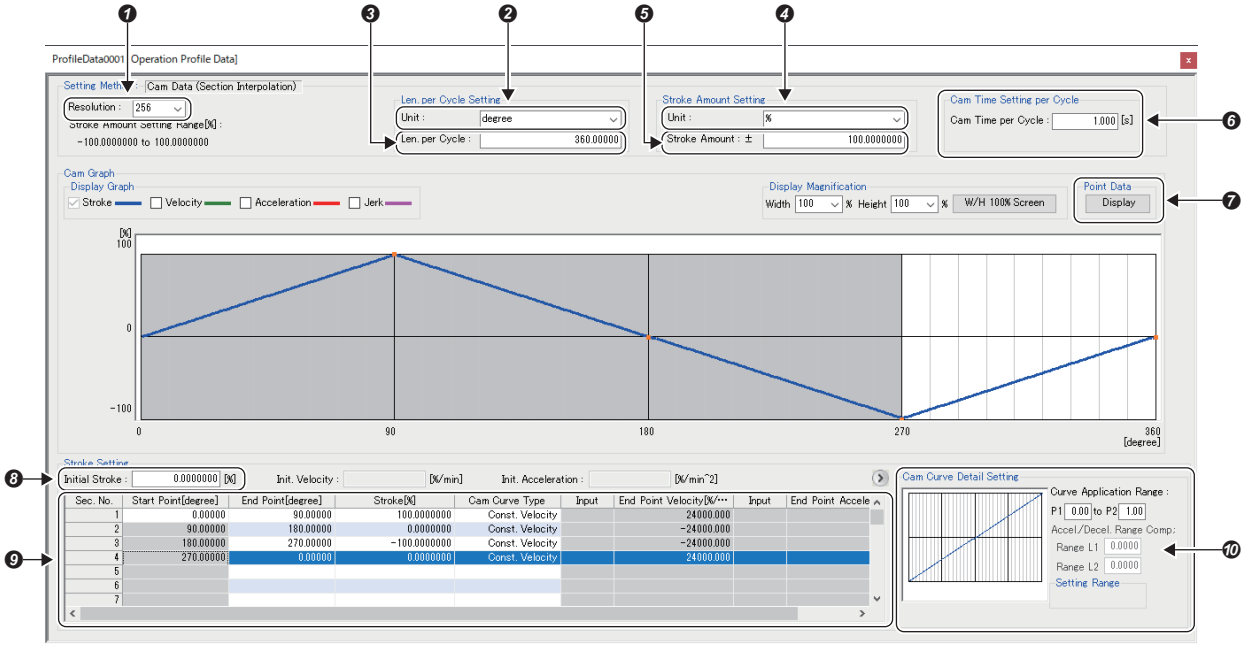


Setting method of operation profile data

This section describes the setting method for using operation profile data in advanced synchronous control.

1. In the Navigation window, right-click [Motion Setting], then [Operation Profile Data] (1), and select [Add New Data] (2).

2. In the "New Data" window, configure the basic settings and detailed settings, and click the [OK] button.

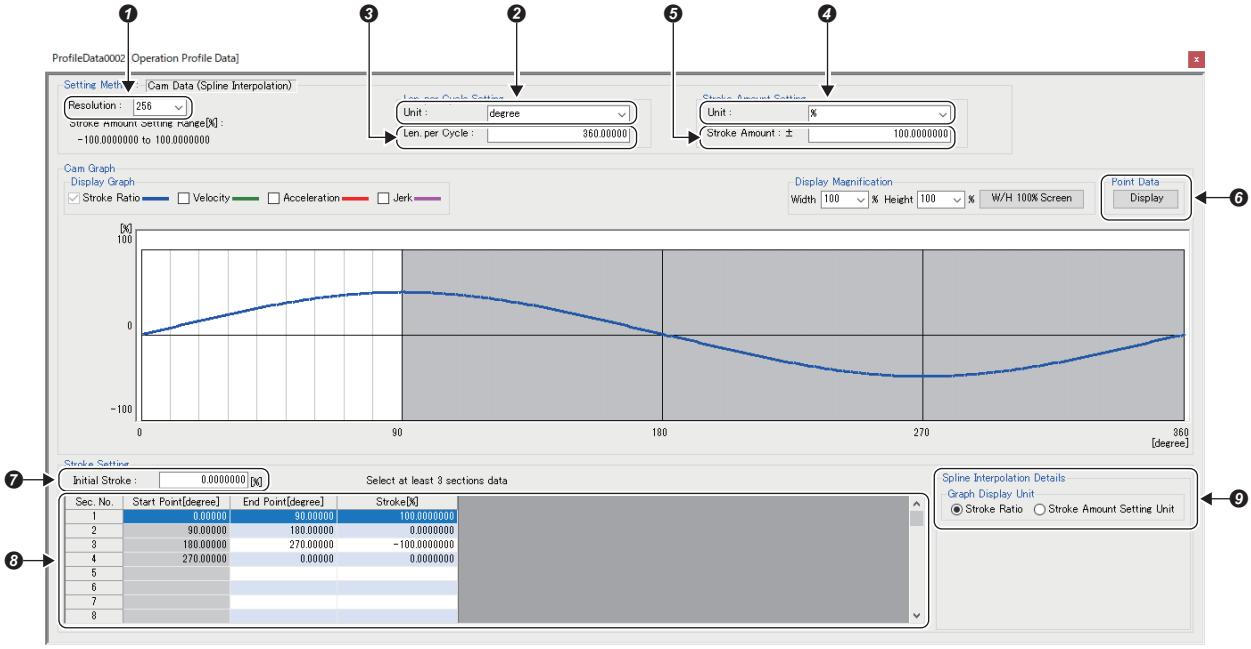


Setting item			Setting
Basic setting	Data type		Set "Operation Profile Data".
	Data name		Set any data name.
Detailed setting	Data format	Type	Set the type of data to be created. • Cam data • Rotary cutter
		Interpolation method specification	Set the interpolation method to match the cam to be created. • Linear interpolation • Section interpolation • Spline interpolation
	Expand setting	Auto expand	To expand the operation profile data automatically, set to "Yes". When set to "No", operation profile data must be stored in the open area by MC_CamTableSelect (Cam Table Selection) to use the operation profile data in the control.
		Profile ID	Set to any value within the range of 1 to 60000.
		Repetitive operation	Set to "Enable".
		Input absolute coordinate	Set to "Disable (Relative Coordinate)".
		Output absolute coordinate	Set to "Disable (Relative Coordinate)".

3. Set the operation profile data. Set as follows according to the set type and interpolation method specification.

- Cam data

■Section interpolation

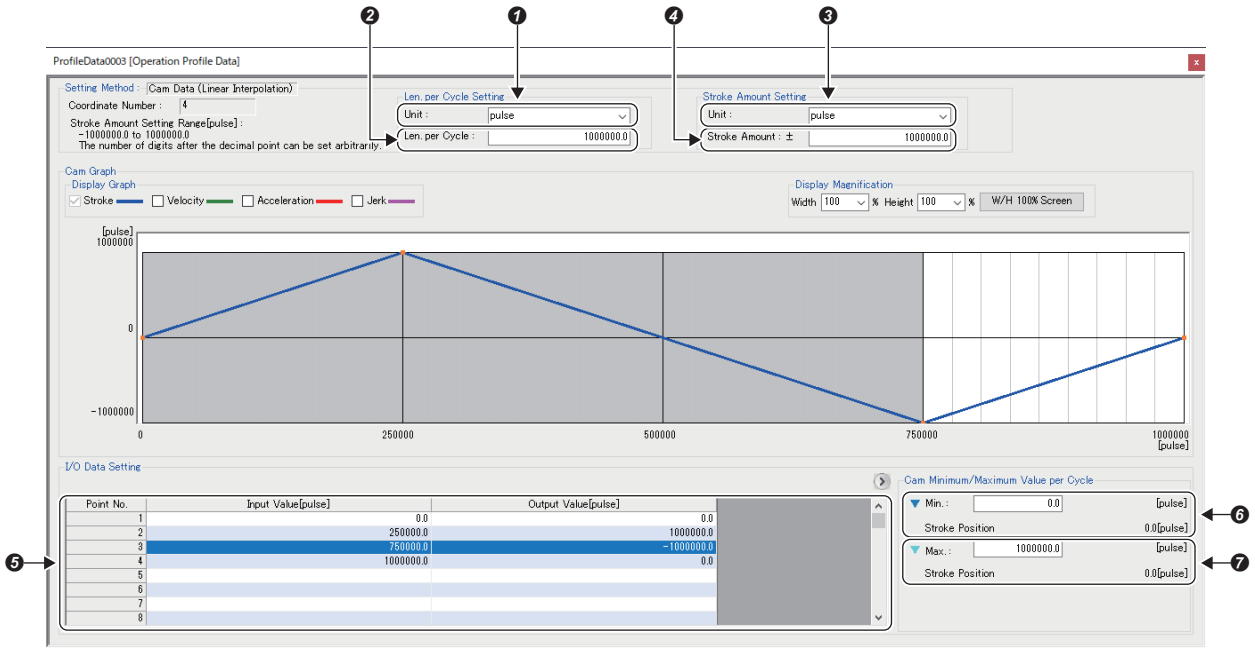


❶ Set the resolution to match the cam data to be created.
❷ Set to the same unit as that of the main shaft. *1
❸ Set to the same value as that set in the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle). *1
❹ Set to any unit.
❺ When the unit is other than "%", set to 100 % stroke amount.
❻ Use when cam curve type is set to "5th Curve (Adj.)".
❼ Click the [Display] button of the point data to check the stroke data of the open area.
❽ Set to "0.0".
❾ Set the input value and the output value to match the cam data to be created. *2
❿ Set the detailed settings to match the cam data to be created. *2

*1 Although the setting is ignored in advanced synchronous control, set this item in order to match the setting window and the actual cam operation.

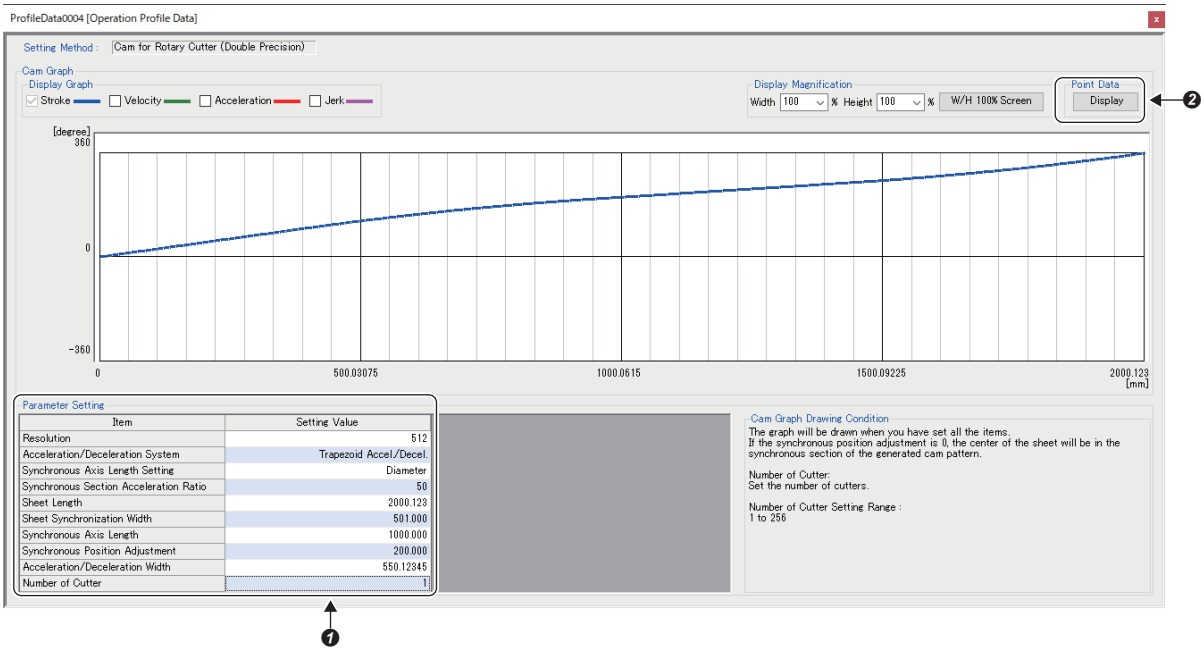
*2 For details, refer to the following.
☞ Page 827 Cam data

■Spline interpolation



❶ Set the resolution to match the cam data to be created.
❷ Set to the same unit as that of the main shaft. *1
❸ Set to the same value as that set in the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle). *1
❹ Set to any unit.
❺ When the unit is other than "%", set to 100 % stroke amount.
❻ Click the [Display] button of the point data to check the stroke data of the open area.
❼ Set to "0.0".
❽ Set the input value and the output value to match the cam data to be created. *2
❾ Set the detailed settings to match the cam data to be created.

*1 Although the setting is ignored in advanced synchronous control, set this item in order to match the setting window and the actual cam operation.



*2 For details, refer to the following.
☞ Page 827 Cam data

■Linear interpolation

❶ Set the unit of the axis to be set as the main shaft.
❷ Set to the same value as that set in the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle).
❸ Set the unit of the axis to be set as the output axis.
❹ Set to a value equal to or more than the maximum value of the output value in the I/O data.
❺ Set the input value and the output value to match the cam data to be created.
❻ Set to "0.0".
❼ Set to the setting value of the Length per cycle (AdvOutputName.Pr.Cam.LengthPerCycle).

• Rotary cutter

❶ Set it to match the cam data to be created.
❷ Click the [Display] button of the point data to check the stroke data of the open area.

Precautions

- When rewriting the open area during control by using the Profile Write (MCv_WriteProfileData), depending on the waveform pattern, the stroke value may change rapidly, causing an impact to be applied to the machine. Create operation profile data so that the waveform before and after the change does not become discontinued.
- For operation profile data format that can be used in the advanced synchronous control, refer to the following. If an unavailable operation profile data format is used in the advanced synchronous control, Operation Profile Data Settings Incorrect Under Advanced Synchronous Control (error code: 1B2AH) will occur.

☞ Page 826 Operation profile data types

- If the Cam No. (AdvOutputName.Pr.Cam.CamNo) is changed during advanced synchronous control in the following cases, a warning occurs, and control continues with the cam data before the change.

Description	Event code
A value out of range for Cam No. (AdvOutputName.Pr.Cam.CamNo) was set.	Out of Advanced Synchronous Control Variable Range Warning (event code: 0D3FH)
The cam table does not exist.	No Cam Table Warning (event code: 0D44H)
A value that cannot be used in advanced synchronous control was set in the operation profile data.	Operation Profile Data Settings Incorrect Under Advanced Synchronous Control Warning (event code: 0D46H)
A value which exceeds the resolution was set to the cam starting point.	Operation Profile Data Settings Incorrect Under Advanced Synchronous Control Warning (event code: 0D46H)
Failed to acquire the add-on ProfileControl.	Add-on Acquisition Failure Warning (event code: 0D47H)

Synchronous control change function

While MCv_AdvancedSync (Advanced Synchronous Control) is activated, this function can be used to change the cam reference position, the current position per cycle, and the current position per cycle after main shaft/auxiliary shaft gear during synchronous control.

The following methods exist for the synchronous control change function. (☞ Page 987 Synchronous control change command (AdvOutputName.Cd.Cam.SyncControlChangeCommand))

Synchronous control change command	Application	Output axis operation
Cam reference position movement	Adjust the cam reference position by the movement amount.	Operated
Change current position per cycle	Change the current position per cycle.	None
Change current position per cycle after main shaft gear	Change the current position per cycle after main shaft gear.	None
Change current position per cycle after auxiliary shaft gear	Change the current position per cycle after auxiliary shaft gear.	None
Current position per cycle movement	Adjust the phase of the cam set position by the movement amount.	Operated

Cam monitor of output axis monitor data (AdvOutputName.Md.Cam.)

Variable name	Name	Import*1	Data type*1	Monitor value
SyncControlChangeStatus	Synchronous control change status	Operation cycle (FB is starting)	INT	• -1: Synchronous control change failure • 0: Synchronous control change not requested • 1: Synchronous control change in progress • 2: Synchronous control change complete

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

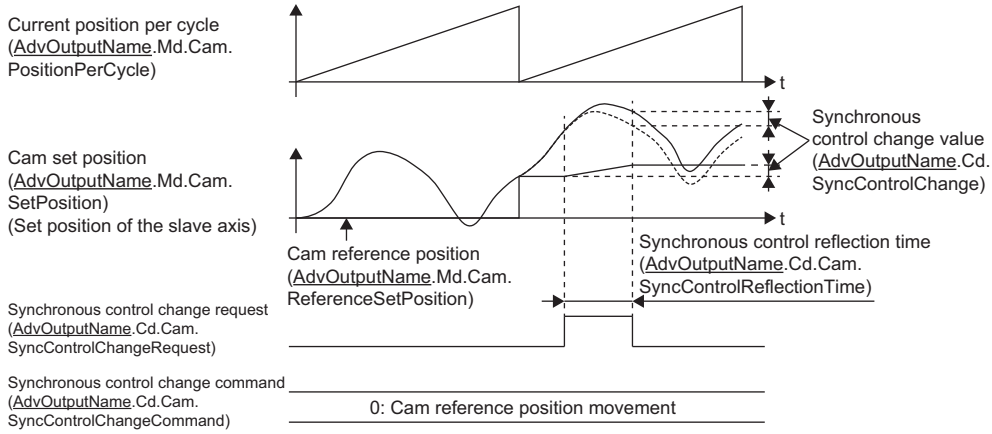
■Synchronous control change status (AdvOutputName.Md.Cam.SyncControlChangeStatus)

- When Synchronous control change request (AdvOutputName.Cd.Cam.SyncControlChangeRequest) is set to "TRUE (Synchronous control change requested)", "1: Synchronous control change in progress" is stored to Synchronous control change status (AdvOutputName.Md.Cam.SyncControlChangeStatus) during synchronous control change processing, and "2: Synchronous control change complete" is stored after processing.
- Synchronous control change status (AdvOutputName.Md.Cam.SyncControlChangeStatus) is "0: Synchronous control change not requested" according to the following conditions.
  - Synchronous control change request (AdvOutputName.Cd.Cam.SyncControlChangeRequest) is set to "FALSE (Synchronous control change not requested".
  - Advanced synchronous control is stopped.
- When Synchronous control change command (AdvOutputName.Cd.Cam.SyncControlChangeCommand) and Synchronous control change value (AdvOutputName.Cd.Cam.SyncControlChange) are set out of range, and Synchronous control change request (AdvOutputName.Cd.Cam.SyncControlChangeRequest) is set to "TRUE (Synchronous control change requested)", "-1: Synchronous control change failure" is stored.

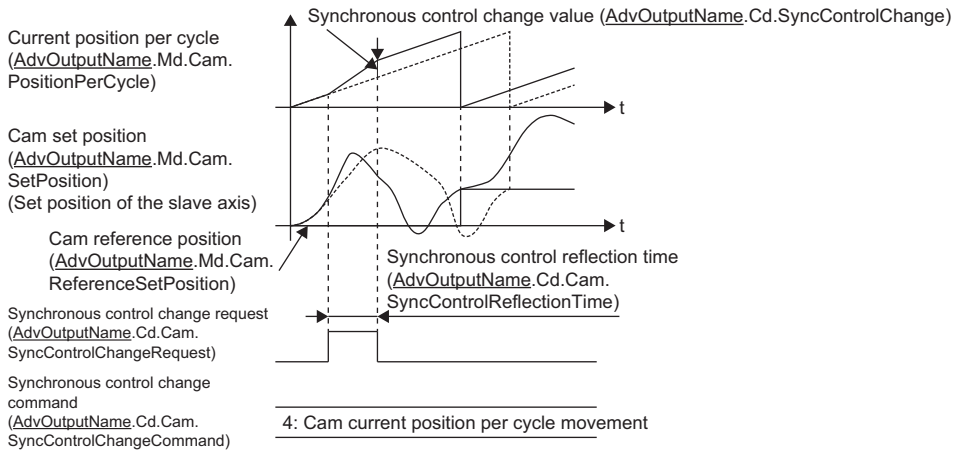
Cam control data of output axis control data (AdvOutputName.Cd.Cam.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
SyncControlChangeRequest	Synchronous control change request	Operation cycle (FB is starting)	BOOL	• FALSE: Synchronous control change not requested • TRUE: Synchronous control change requested	FALSE
SyncControlChangeCommand	Synchronous control change command		INT (MC_SYNC_CHANGE_COMMAND)	• 0: Cam reference position movement (ReferenceSetPositionMovement) • 1: Change current position per cycle (ChangeCurrentPositionPerCycle) • 2: Change current position per cycle after main shaft gear (ChangeMasterGearPositionPerCycle) • 3: Change current position per cycle after auxiliary shaft gear (ChangeAuxGearPositionPerCycle) • 4: Current position per cycle movement (PositionPerCycleMovement)	0: Cam reference position movement (ReferenceSetPositionMovement)
SyncControlChange	Synchronous control change value		LREAL	-2147483648.0 to 2147483647.0	0.0
SyncControlReflectionTime	Synchronous control change value reflection time		WORD (UINT)	0 to 65535 [ms]	0 [ms]

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual



■Synchronous control change request (AdvOutputName.Cd.Cam.SyncControlChangeRequest)



The synchronous control change is requested.

When set to "TRUE (Synchronous control change requested)", Synchronous control change command (AdvOutputName.Cd.Cam.SyncControlChangeCommand) is executed.

■Synchronous control change command (AdvOutputName.Cd.Cam.SyncControlChangeCommand)

Set the synchronous control change command.

Synchronous control change command	Description
0: Cam reference position movement (ReferenceSetPositionMovement)	This command is executed to move the cam reference position through adding the setting movement amount of Synchronous control change value (AdvOutputName.Cd.Cam.SyncControlChange). The movement amount is added after being averaged in Synchronous control change reflection time (AdvOutputName.Cd.Cam.SyncControlReflectionTime). Set a long reflection time when a large movement amount is used since the cam set position moves with the movement amount.  • When Synchronous control change request (AdvOutputName.Cd.Cam.SyncControlChangeRequest) is reset to "FALSE (Synchronous control change not requested)" while executing the cam reference position movement, operation is stopped midway. Even if the cam reference position movement command is executed again, the remaining movement amount is not reflected, and the control is performed with a new Synchronous control change value (AdvOutputName.Cd.SyncControlChange) imported. • If synchronous control is ended while the cam reference position movement is being executed, operation stops midway. Even if synchronous control is restarted, the remaining movement amount of the cam reference position is not reflected.
1: Change current position per cycle (ChangeCurrentPositionPerCycle)	The current position per cycle is changed to Synchronous control change value (AdvOutputName.Cd.Cam.SyncControlChange). The cam reference position will be also changed to correspond to the changed current position per cycle. This operation is completed in one operation cycle.
2: Change current position per cycle after main shaft gear (ChangeMasterGearPositionPerCycle)	The current position per cycle after main shaft gear is changed to the value set in Synchronous control change value (AdvOutputName.Cd.Cam.SyncControlChange). This operation is completed in one operation cycle. Clutch control is not executed if the current position per cycle after main shaft gear (the position before being changed and after being changed) has already passed through the ON/OFF address in address mode.
3: Change current position per cycle after auxiliary shaft gear (ChangeAuxGearPositionPerCycle)	The current position per cycle after auxiliary shaft gear is changed to the value set in Synchronous control change value (AdvOutputName.Cd.Cam.SyncControlChange). This operation is completed in one operation cycle. Clutch control is not executed if the current position per cycle after auxiliary shaft gear (the position before being changed and after being changed) has already passed through the ON/OFF address in address mode.

Synchronous control change command	Description
4: Current position per cycle movement (PositionPerCycleMovement)	This command is executed to move the current position per cycle through adding the setting movement amount of Synchronous control change value (AdvOutputName.Cd.Cam.SyncControlChange). The movement amount is added after being averaged in Synchronous control change reflection time (AdvOutputName.Cd.Cam.SyncControlReflectionTime). Set a long reflection time when a large movement amount is used since the cam set position moves with the movement amount. 

■Synchronous control change value (AdvOutputName.Cd.Cam.SyncControlChange)

Set the change value for synchronous control change processing.

Synchronous control change command (AdvOutputName.Cd.Cam.SyncControlChangeCommand)	Synchronous control change value (AdvOutputName.Cd.Cam.SyncControlChange)		
	Setting range	Unit	Setting details
0: Cam reference position movement (ReferenceSetPositionMovement)	-2147483648.0 to 2147483647.0	Position units of the axis set in the output axis	• Set the movement amount of the cam reference position. • It moves within the range from -2147483648.0 to 2147483647.0.
1: Change current position per cycle (ChangeCurrentPositionPerCycle)			• Set the change current position per cycle. • The setting value is converted within the range from "0.0 to (length per cycle - 0.00001)".
2: Change current position per cycle after main shaft gear (ChangeMasterGearPositionPerCycle)			
3: Change current position per cycle after auxiliary shaft gear (ChangeAuxGearPositionPerCycle)			
4: Current position per cycle movement (PositionPerCycleMovement)			• Set the movement amount of the current position per cycle. • It moves within the range from -2147483648 to 2147483647.

■Synchronous control change value reflection time (AdvOutputName.Cd.Cam.SyncControlReflectionTime)

Set the reflection time for synchronous control change processing.

Synchronous control change command (AdvOutputName.Cd.Cam.SyncControlChangeCommand)	Setting details for Synchronous control change reflection time (AdvOutputName.Cd.Cam.SyncControlReflectionTime)
0: Cam reference position movement (ReferenceSetPositionMovement)	Set the time to reflect the movement amount to the cam reference position.
1: Change current position per cycle (ChangeCurrentPositionPerCycle)	Setting not required.
2: Change current position per cycle after main shaft gear (ChangeMasterGearPositionPerCycle)	
3: Change current position per cycle after auxiliary shaft gear (ChangeAuxGearPositionPerCycle)	
4: Current position per cycle movement (PositionPerCycleMovement)	The time to reflect the movement amount to the current position per cycle.

Precautions

The following are precautions when operating an output axis.

- Do not set digits after the decimal point in the Ring counter lower limit value (AxisName.PrConst.RingCount_LowerValue) and Ring counter upper limit value (AxisName.PrConst.RingCount_UpperValue) of the positioning range of the axis set in the output axis Axis information (AdvOutputName.Axis). If set, an error will occur with the value output to the slave axis and the Set position (AxisName.Md.SetPosition) of the axis set to the output axis in synchronous control when the permissible value is exceeded.
- When the intermediate result of the movement amount calculated by each module exceeds the range of "-2147483648.0 to 2147483647.0", Advanced Synchronization Control Operation Overflow (error code: 1B23H) occurs. Check the function of the module in which the overflow occurred with the detail code. The detail codes of Advanced Synchronous Control Operation Overflow (error code: 1B23H) are shown below.

Function of the module in which the overflow occurred	Detail code	Action
Composite main shaft gear	0001H	Reduce the speed of the main shaft main input axis and the main shaft sub input axis.
Main shaft gear	0002H	Reduce the gear ratio (gear numerator/gear denominator).
Main shaft clutch	0003H	Reduce the speed of the input axis when a clutch is used.
Main shaft module speed change gear	0004H	Reduce the speed change ratio (speed change ratio numerator/speed change ratio denominator).
Auxiliary shaft	0005H	Reduce the set velocity of the axis set as the auxiliary shaft.
Auxiliary shaft gear	0006H	Reduce the gear ratio (gear numerator/gear denominator).
Auxiliary shaft clutch	0007H	Reduce the speed of the input axis when a clutch is used.
Auxiliary shaft module speed change gear	0008H	Reduce the speed change ratio (speed change ratio numerator/speed change ratio denominator).
Composite auxiliary shaft gear	0009H	Reduce the input value of the main shaft and the auxiliary shaft.
Output axis speed change gear	000AH	Reduce the speed change ratio (speed change ratio numerator/speed change ratio denominator).
Output axis phase compensation	000BH	Reduce the value of phase compensation advance time or increase the phase compensation time constant.
Output axis smoothing	000CH	Review the setting value of the time constant so that the number of smoothing steps reduces or increase the setting value of the operation cycle.
Output axis synchronous control change	000DH	Reduce the synchronous control change value or increase the synchronous control change reflection time.
Output axis cam calculation	000EH	Review the cam waveform so that the stroke does not vary rapidly.

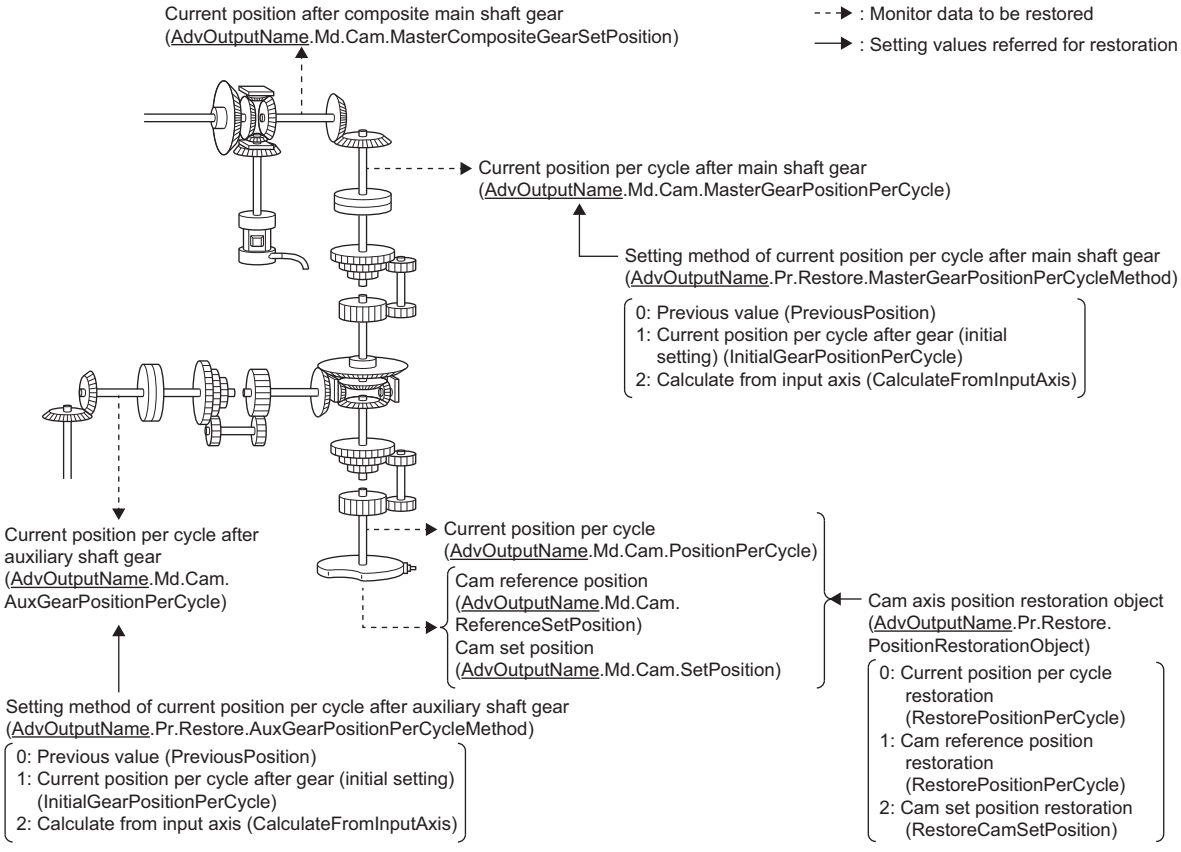
Required object data

The following shows the starting availability condition with or without PDO mapping when using it as the Output axis (AdvOutputName.Axis) of MCv_AdvancedSync (Advanced Synchronous Control).

PDO mapping necessary/not necessary	
Target position	**Position actual Value**
Necessary	Not required
Not necessary	Necessary
Not necessary	Not necessary

33.5 Synchronous Control Initial Position

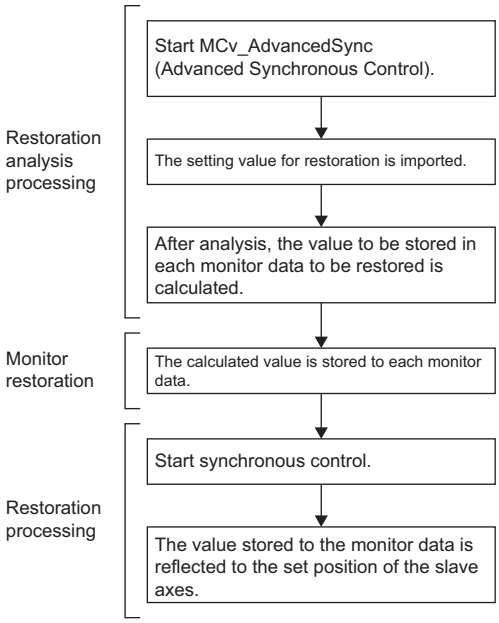
The synchronous control monitor data can be aligned to a set position when starting MCv_AdvancedSync (Advanced Synchronous Control), as the initial position for synchronous control. Restoration is executed when MCv_AdvancedSync (Advanced Synchronous Control) is started.



The alignment to a synchronous control initial position is useful for restoring a system based on the last control status along with restarting synchronous control after cancelling midway.

The following monitor data are restored to a synchronous control initial position. To restore the data, the axes set in the axis information of the input axis and output axis must be set to an absolute position detection system.

Synchronous control monitor data		The position when starting synchronous control
Name	**Variable name**	
Current position after composite main shaft gear	AdvOutputName.Md.Cam.MasterCompositeGearSetPosition	Restored to a position based on the current position of the input axis of the main shaft.
Current position per cycle after main shaft gear	AdvOutputName.Md.Cam.MasterGearPositionPerCycle	Restored according to the Setting method of current position per cycle after main shaft gear (AdvOutputName.Pr.Restore.MasterGearPositionPerCycleMethod).
Current position per cycle after auxiliary shaft gear	AdvOutputName.Md.Cam.AuxGearPositionPerCycle	Restored according to the Setting method of current position per cycle after auxiliary shaft gear (AdvOutputName.Pr.Restore.AuxGearPositionPerCycleMethod).
Current position per cycle	AdvOutputName.Md.Cam.PositionPerCycle	Restored according to the Cam axis position restoration object (AdvOutputName.Pr.Restore.PositionRestorationObject).
Cam reference position	AdvOutputName.Md.Cam.ReferenceSetPosition	
Cam set position*1	AdvOutputName.Md.Cam.SetPosition	



*1 The Set position (AxisName.Md.SetPosition) of the axis set as the output axis of the advanced synchronous control is calculated based on the cam set position.

The relationship between each module, the monitor data to be restored, and the setting values referred to for restoration is shown below.

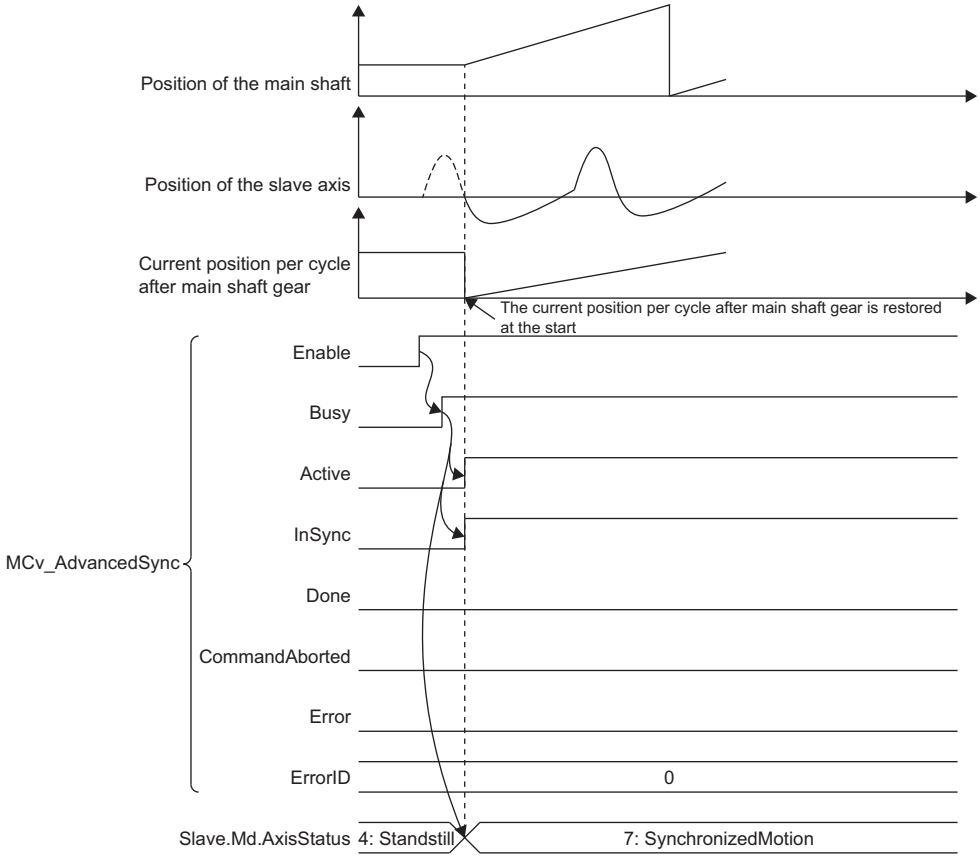
Restoration processing method

The restoration processing method is shown below. Restoration is executed in the following order: restoration analysis, monitor restoration, and restoration processing.

Backup data management for advanced synchronous control

For advanced synchronous control, the initial value of synchronous control monitor data and the data used to calculate and restore the synchronous control initial position are periodically saved to the latch drive as "abs_advsync.bin" file.
In order to back up data, the add-on AbsSystem must be valid.
When the axes set in the axis information of the input axis and output axis are not set to an absolute position detection system, backup data is not generated.
An "abs_advsync.bin" file of size up to the size specified in the Maximum backup RAM size (AddonSystem.PrConst.AddonMemory.BackupRamSizeMax) can be saved. If the total size of the backup data exceeds the limit for backup data when adding the input axis and output axis, the variable that exceeds the limit will not be added.
When the total size of the backup data exceeds the limit, Advanced Synchronous Control Backup Memory Insufficient Warning (event code: 00F18H) occurs.
The backup data size for an input axis and an output axis is shown below.

Axis type	Backup data size (k byte)
Input axis	0.1
Output axis	0.1



When turning the system power on again after setting a smaller value set in the Maximum backup RAM size (AddonSystem.PrConst.AddonMemory.BackupRamSizeMax) than the last time the system was powered on, the "abs_advsync.bin" file will be regenerated, and all backup data will be cleared. As the backup data is linked to the label IDs of the input axis and output axis, when the target axis No. specified in the input axis labels and output axis labels is changed before/after the system is powered on again, restoration cannot be performed correctly because the links are broken. If restoration cannot be performed correctly, Advanced Synchronous Control Restoration Incorrect Warning (event code: 0D40H) occurs.

Restoration method for current position after composite main shaft gear, current position per cycle after main shaft gear, and current position per cycle after auxiliary shaft gear at start of synchronous control

The initial position alignment and restoration of the current position after composite main shaft gear, the current position per cycle after main shaft gear, and the current position per cycle after auxiliary shaft gear are executed when MCv_AdvancedSync (Advanced Synchronous Control) is started.

Ex.

When the current position per cycle after main shaft gear is restored

Restoration method

The current position after composite main shaft gear, the current position per cycle after main shaft gear, and the current position per cycle after auxiliary shaft gear are restored as follows according to the operations executed on the axes assigned to the main shaft or auxiliary shaft before starting MCv_AdvancedSync (Advanced Synchronous Control).

Operation of the axes assigned to the main shaft and auxiliary shaft (before starting MCv_AdvancedSync (Advanced Synchronous Control))	Absolute position management setting (AxisName.PrConst.PosRestoration_AbsPosEnable) of the axes set in the input axis Axis information	
	Absolute position detection system valid	Absolute position detection system invalid
Execution of MC_Home (Home Position Return)	Restoration method (1)	
Execution of MC_SetPosition (Current Position Change)	Restoration method (1)	
Transition of the Active status (AdvInputName.Md.ActiveStatus) of input axis from"0: Not connected" to "1: Input axis enabled".	Restoration method (2)	Restoration method (1)
Others	Restoration method (2)	

Precautions

- The input axis value is rounded to a value within the positioning range, and the difference between this value and the current position of the input axis when synchronous control was last conducted is used as the change amount in "Restoration method (2)".
- When the input axis movement since synchronous control was last conducted exceeds "±10000000000.0 [input axis unit]" before synchronous control starts, the change amount cannot be calculated correctly.

■Restoration method (1)

Setting item	Restoration method	Calculation formula
Current position after composite main shaft gear	The new current position after composite main shaft gear is calculated based on the input axis cumulative current position of the main shaft.	Input direction of composite main shaft gear*1 × Cumulative current position of the input axis (main shaft)
Current position per cycle after main shaft gear	The new current position per cycle after main shaft gear is calculated based on the current position after composite main shaft gear.	Main shaft gear ratio*2 × Current position after composite main shaft gear
Current position per cycle after auxiliary shaft gear	The new current position per cycle after auxiliary shaft gear is calculated based on the input axis cumulative current position of the auxiliary shaft.	Auxiliary shaft gear ratio*2 × Cumulative current position of the input axis (auxiliary shaft)

*1 The "Input direction of composite main shaft gear" value in the formula is as follows according to the Composite main shaft gear (AdvOutputName.Pr.Gear.MasterCompositeGear).

Composite main shaft gear (AdvOutputName.Pr.Gear.MasterCompositeGear)	Setting value for "Input direction of composite main shaft gear"
No input (H□□□0)	0
Input+ (H□□□1)	1
Input- (H□□□2)	-1

*2 The gear ratio of the main and auxiliary shafts is calculated by the following formula.

Item	Calculation formula
Main shaft gear ratio	$\frac{\text{Main shaft gear: Numerator (AdvOutputName.Pr.Gear.MasterNumerator)}}{\text{Main shaft gear: Denominator (AdvOutputName.Pr.Gear.MasterDenominator)}}$
Auxiliary shaft gear ratio	$\frac{\text{Auxiliary shaft gear: Numerator (AdvOutputName.Pr.Gear.AuxNumerator)}}{\text{Auxiliary shaft gear: Denominator (AdvOutputName.Pr.Gear.AuxDenominator)}}$

■Restoration method (2)

The movement amount of the main shaft, sub input axis, or auxiliary shaft from the last synchronous control session is reflected to the current position after composite main shaft gear, the current position per cycle after main shaft gear, and the current position per cycle after auxiliary shaft gear.

Setting item	Restoration method	Calculation formula
Current position after composite main shaft gear	The movement amount of the main shaft from the last synchronous control session is reflected to the current position after composite main shaft gear.	Current position after composite main shaft gear at the last synchronous control session + Input direction of composite main shaft gear × Amount of change in the cumulative current position of input axis (main shaft) from the last synchronous control session
Current position per cycle after main shaft gear	The movement amount from the last synchronous control session is reflected to the current position per cycle after main shaft gear. The movement amount of the main shaft from the last synchronous control session is reflected to the current position after composite main shaft gear and the current position per cycle after main shaft gear.	Current position per cycle after main shaft gear at the last synchronous control session + Main shaft gear ratio × Amount of change in the current position after composite main shaft gear from the last synchronous control session
Current position per cycle after auxiliary shaft gear	The movement amount from the last synchronous control session is reflected to the current position per cycle after auxiliary shaft gear. The movement amount of the auxiliary shaft from the last synchronous control session is reflected to the current position per cycle after auxiliary shaft gear.	Current position per cycle after auxiliary shaft gear at the last synchronous control session + Auxiliary shaft gear ratio × Amount of change in the cumulative current position of input axis (auxiliary shaft) from the last synchronous control session

Point

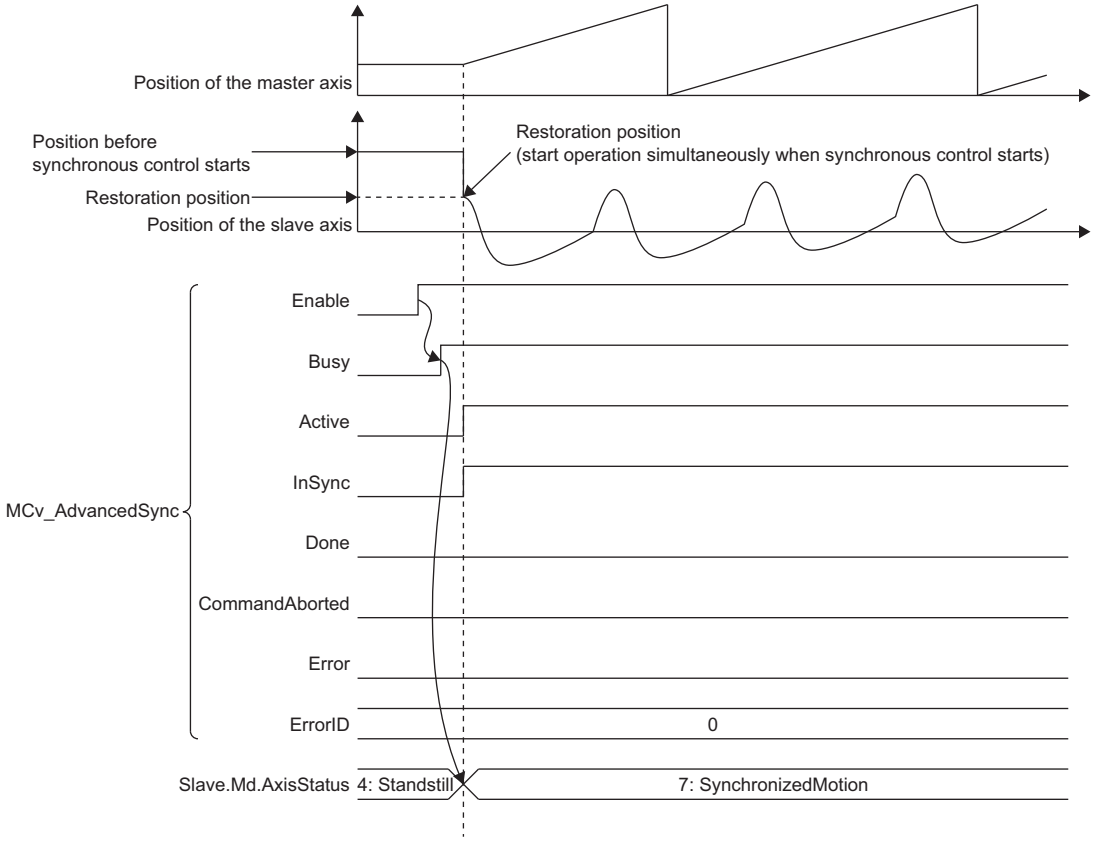
As shown below, the expression "at the last synchronous control session" refers to the state immediately before MCv_AdvancedSync (Advanced Synchronous Control) is interrupted and Synchronization status (AdvOutputName.Md.SyncStatus) changes to "0: Not synchronizing".

- Immediately before MCv_AdvancedSync (Advanced Synchronous Control) is stopped by a stop command or error.
- Immediately before the power supply of the motion system is turned off

Cam axis position at synchronous control start

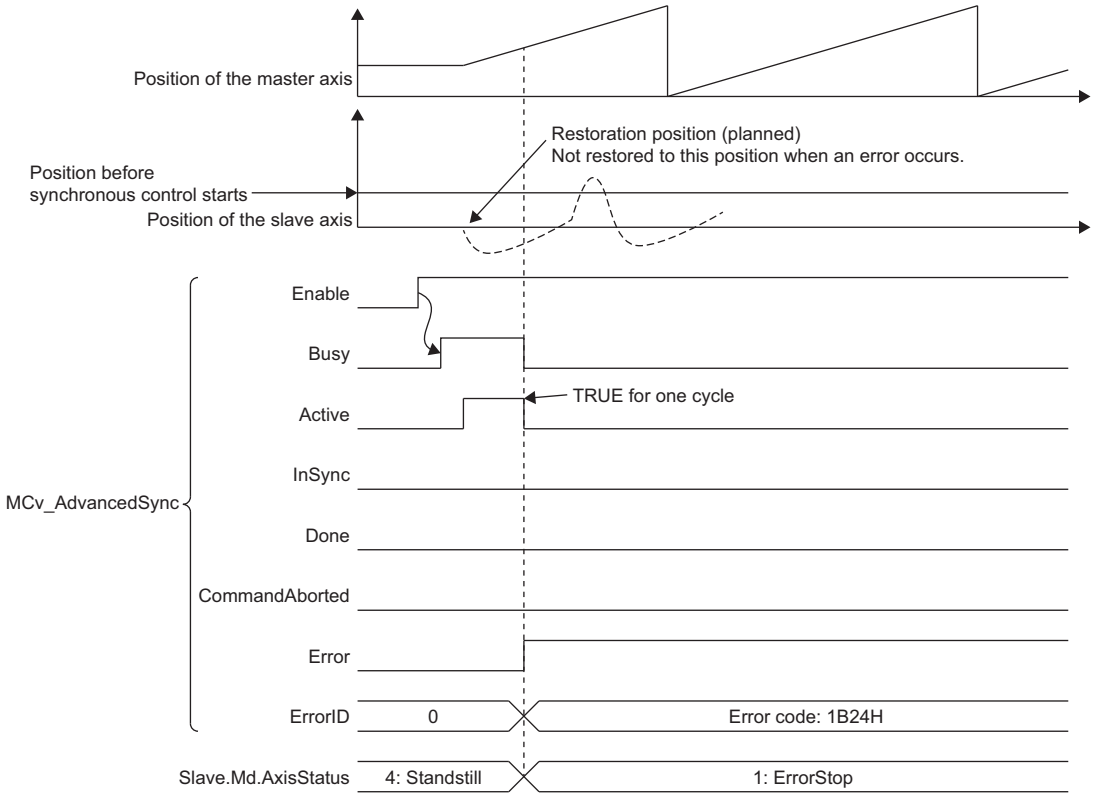
The cam axis position is composed of the relationship of the three positions "Current position per cycle", "Cam reference position", and "Cam set position". The remaining position can be restored by determining two positions when starting MCv_AdvancedSync (Advanced Synchronous Control). Determine which position to restore by selecting one of the following shown below in the Cam axis position restoration object (AdvOutputName.Pr.Restore.PositionRestorationObject).

- 0: Current position per cycle restoration (RestorePositionPerCycle)
- 1: Cam reference position restoration (RestoreReferenceSetPosition)
- 2: Cam set position restoration (RestoreCamSetPosition)



The parameters that need to be set for the cam axis position restoration are shown below. (For details on the settings, refer to synchronous control initial position parameter.) (☞ Page 1005 Variables related to synchronous control initial position)

○: Required, △: Required when using initial setting value, —: Not required

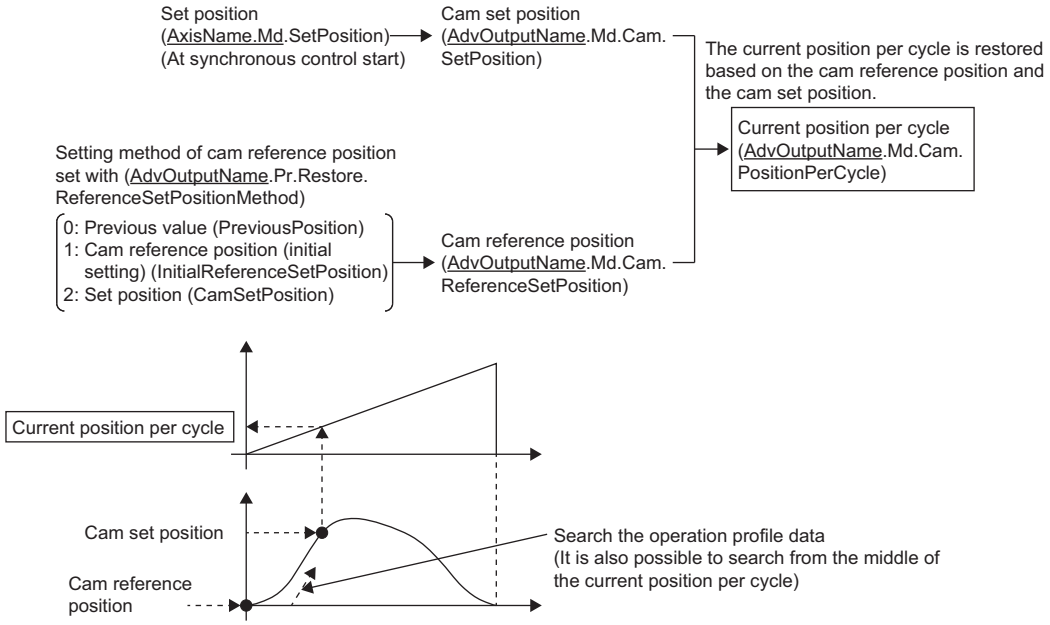


Cam axis position restoration object (AdvOutputName.Pr.Restore.PositionRestorationObject)	Setting method of cam reference position (AdvOutputName.Pr.Restore.ReferenceSetPositionMethod)	Cam reference position (initial setting) (AdvOutputName.Pr.Restore.InitialReferenceSetPosition)	Setting method of current position per cycle (AdvOutputName.Pr.Restore.PositionPerCycleMethod)	Current position per cycle (initial setting) (AdvOutputName.Pr.Restore.InitialPositionPerCycle)	Restoration processing details
0: Current position per cycle restoration (RestorePositionPerCycle)	○	△	—	○ (Used as search starting position)	Restores "current position per cycle" based on "cam reference position" and "cam set position".
1: Cam reference position restoration (RestoreReferenceSetPosition)	—	—	○	△	Restores "cam reference position" based on "current position per cycle" and "cam set position".
2: Cam set position (RestoreCamSetPosition)	○	△	○	△	Restores "cam set position" based on "current position per cycle" and "cam reference position".

The initial position alignment and restoration of the cam axis position are executed when MCv_AdvancedSync (Advanced Synchronous Control) is started.

- A timing chart when cam restoration is normally executed

- A timing chart when an error occurs in cam output axis restoration



Current position per cycle restoration

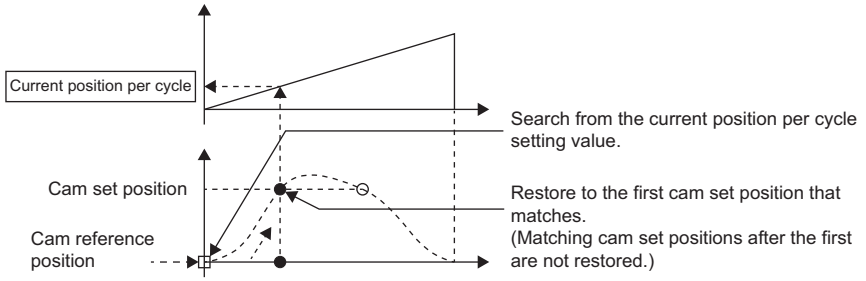
If synchronous control is attempted with Cam axis position restoration object (AdvOutputName.Pr.Restore.PositionRestorationObject) set to "0: Current position per cycle restoration (RestorePositionPerCycle)", the current position per cycle will be restored based on the cam reference position and the cam set position, and MCv_AdvancedSync (Advanced Synchronous Control) will start.

Set the cam reference position to be used for restoration with a parameter. The cam set position uses the set position of the output axis set to the slave axis when MCv_AdvancedSync (Advanced Synchronous Control) starts.

The current position per cycle restoration is calculated by searching from the beginning to the end of the cam pattern for the corresponding current position per cycle. The starting position for searching the cam pattern is set with the Current position per cycle (initial setting) (AdvOutputName.Pr.Restore.InitialPositionPerCycle). (It can be searched from the return path in a two-way operation cam pattern.)

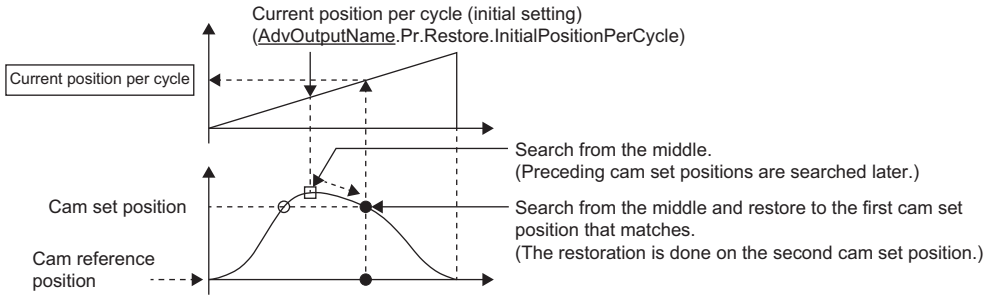
*1 The current position per cycle indicated by [ ] is restored.

- With a two-way operation cam pattern, if the corresponding current position per cycle is not found, Advanced Synchronous Control Restoration Disabled (error code: 1B24H) occurs, and MCv_AdvancedSync (Advanced Synchronous Control) cannot start.
- With a feed operation cam pattern, if the corresponding current position per cycle is not found in the first cycle, the cam reference position is changed automatically and the position is searched again.
- If the cam resolution is large, search processing may take a long time when starting synchronous control. For an approximate guide of the searching time, refer to the following.



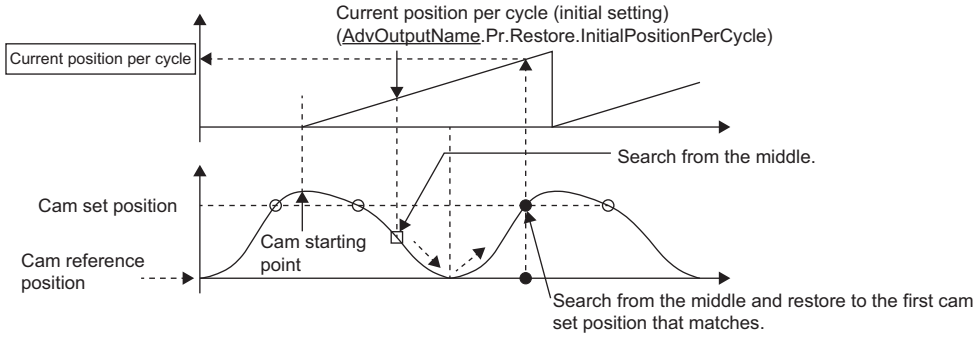
☞ Page 1008 Restoration time of the current position per cycle

- When the Ring counter lower limit value (AxisName.PrConst.RingCount_LowerValue) of the output axis positioning range is "0.0", the current position is not restored in a cam stroke range that crosses over "0.0", and Advanced Synchronous Control Restoration Disabled (error code: 1B24H) occurs. Execute the current position per cycle restoration within a cam stroke range between 0 and the Ring counter upper limit value (AxisName.PrConst.RingCount_UpperValue) of the positioning range.
- When the difference between the cam reference position and the cam set position exceeds "10000000000.0" at restoration, the current position per cycle cannot be restored correctly. Adjust the values so that the difference between the cam reference position and the cam set position is smaller than "10000000000.0" for restoration.

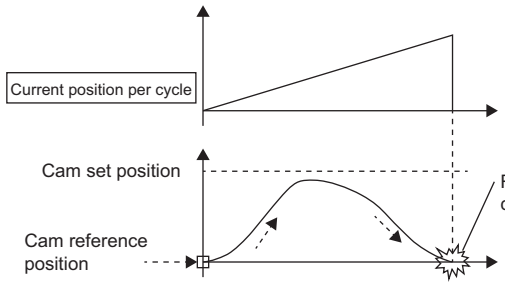


The following shows details of the current position per cycle restoration operation.

■Current position per cycle restoration operation with a "two-way operation cam pattern"

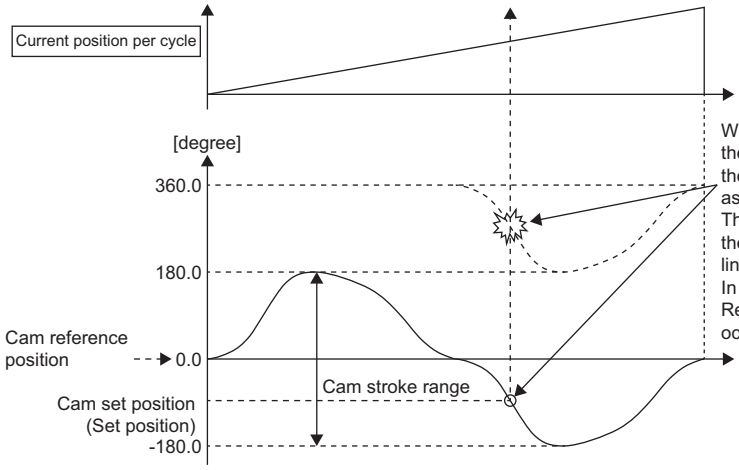


- Search from "Current position per cycle = 0" (Cam starting point = 0)

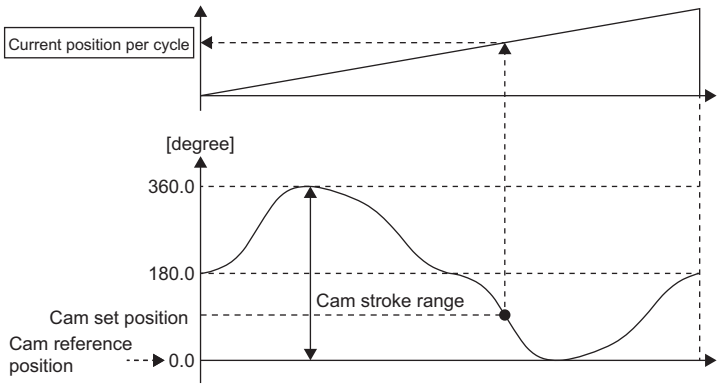


- Search from the middle of the current position per cycle (Cam starting point = 0)

- Search from the middle of the current position per cycle (Cam starting point ≠ 0)

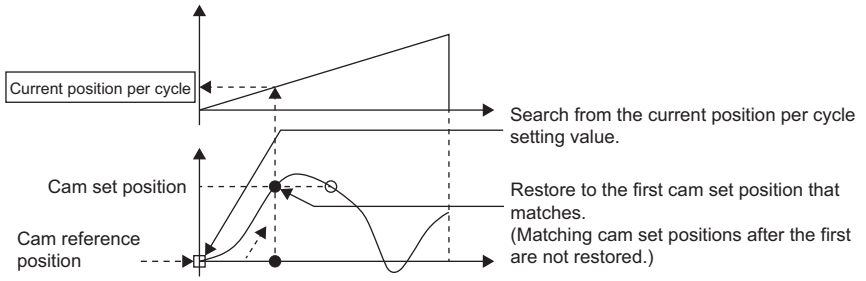


- The search fails
  - When a matching cam set position is not found



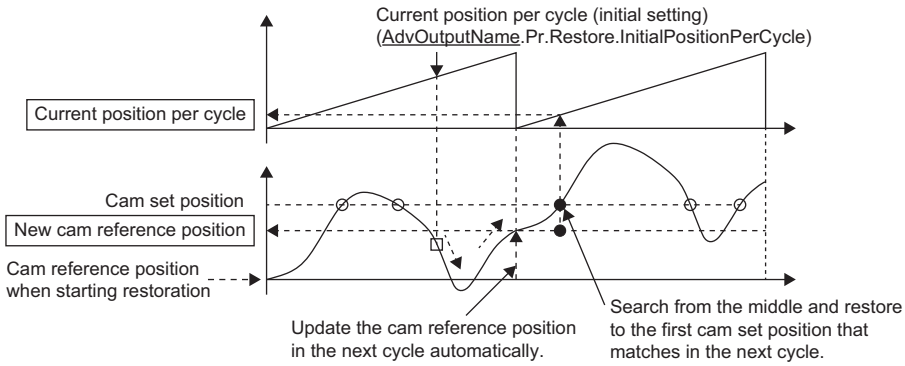
Restoration fails if there is no match found for the cam set position within one cycle.

  - When the current position restoration is executed in a cam stroke range that crosses over "0.0" (the positioning range is "0.0 to 360.0 degrees")

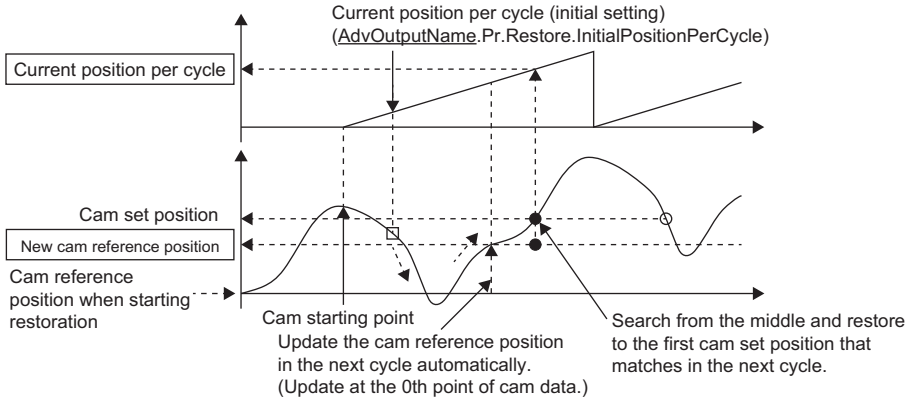


When the cam stroke amount is "180.0" and the positioning range is "0.0 to 359.99999", the cam stroke range is "-180.0 to 179.99999" as shown by the solid line in the graph.
The current position per cycle is restored to the cam set position as shown by the dotted line in the graph.
In this case, "Advanced Synchronous Control Restoration Disabled (error code: 1B24H)" occurs, and the search fails.

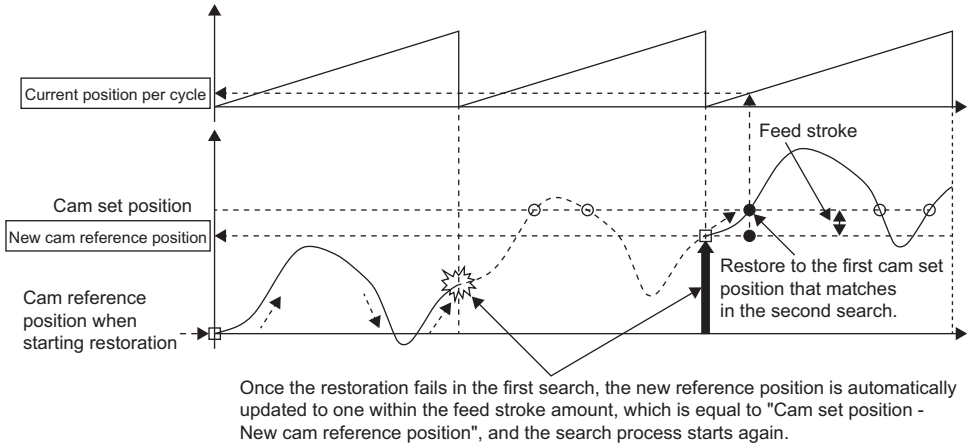
  - In the case above, execute current position restoration within a cam stroke range of the positioning range (0.0 to 360.0 degrees).



■Current position per cycle restoration operation with a "feed operation cam pattern"



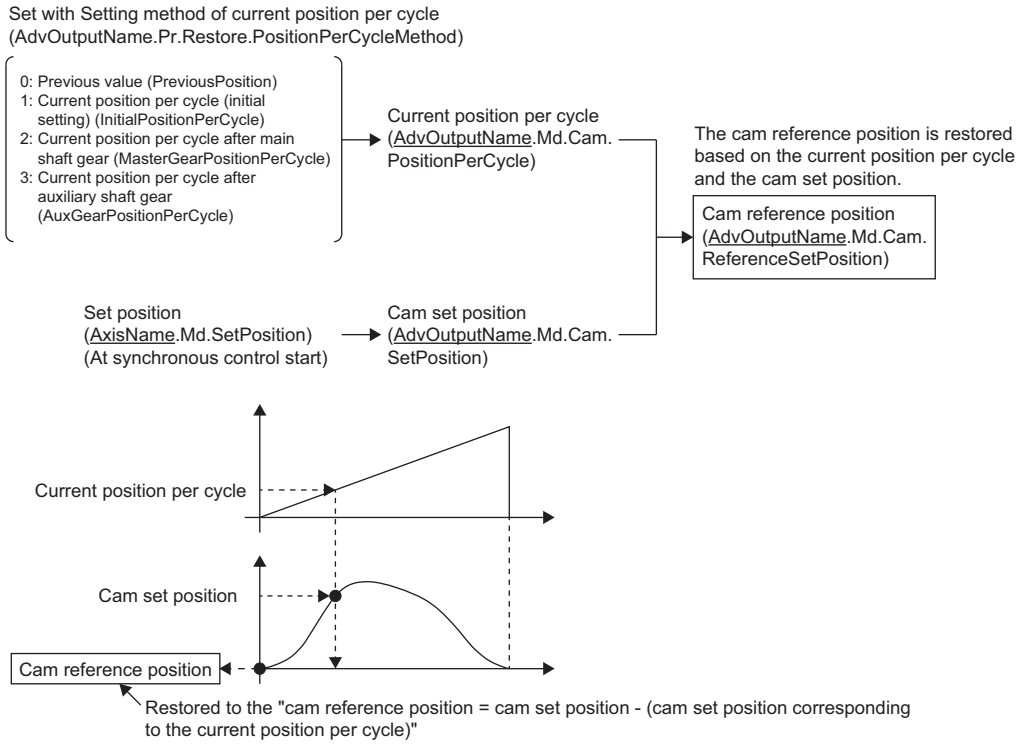
- Search from "Current position per cycle = 0" (Cam starting point = 0)



- Search from the middle of the current position per cycle (Cam starting point = 0)

- Search from the middle of the current position per cycle (Cam starting point ≠ 0)

- The first search fails and a search begins for the second time

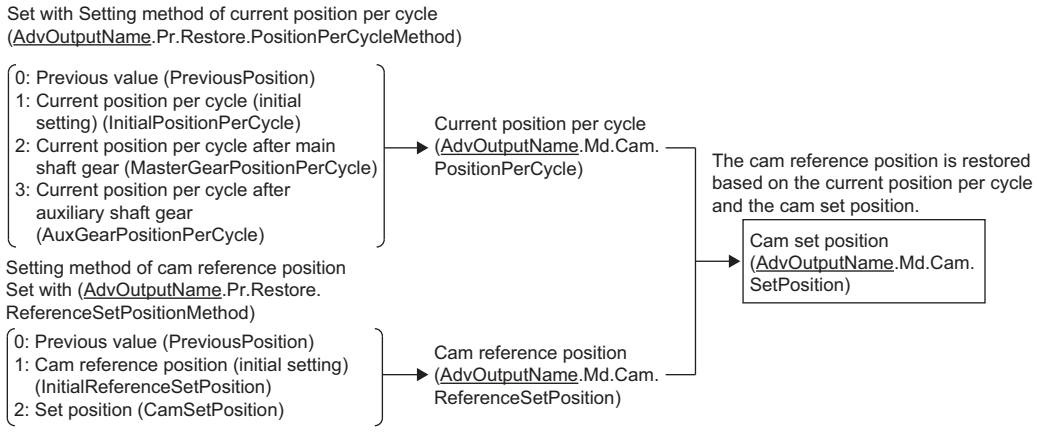


Once the restoration fails in the first search, the new reference position is automatically updated to one within the feed stroke amount, which is equal to "Cam set position - New cam reference position", and the search process starts again.

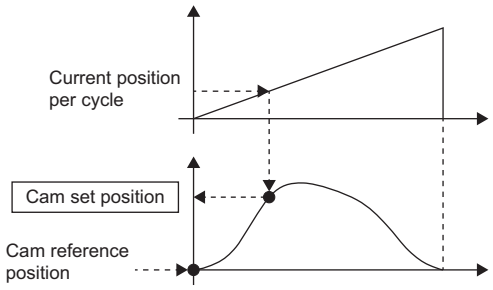
Point

If the first search fails, a second search may not be processed on the next cycle for a cam pattern with a feed stroke that is smaller than 100% of the stroke as above.
The intended current position per cycle can be found in the first search, by setting or positioning the cam reference position in advance.

Cam reference position restoration



If synchronous control is attempted with Cam axis position restoration object (AdvOutputName.Pr.Restore.PositionRestorationObject) set to "1: Cam reference position restoration (RestorePositionPerCycle)", the cam reference position will be restored based on the current position per cycle and the cam set position, and synchronous control will start. Set the current position per cycle to be used for restoration with the parameter.



*1 The cam reference position indicated by [ ] is restored.

Cam set position restoration

If synchronous control is attempted with Cam axis position restoration object (AdvOutputName.Pr.Restore. PositionRestorationObject) set to "2: Cam set position restoration (RestoreCamSetPosition)", the cam set position will be restored based on the current position per cycle and the cam reference position, and synchronous control will start. Set the current position per cycle and cam reference position to be used for restoration with the parameter.

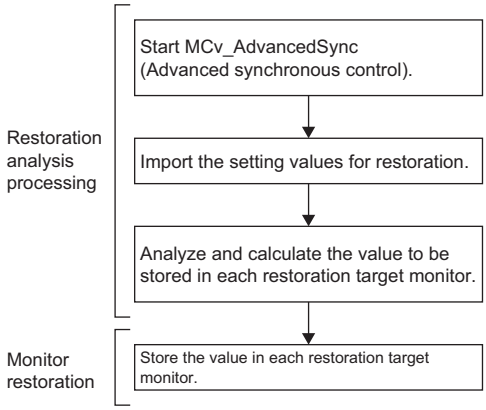
*1 The cam set position indicated by ☐ is restored.

Point

The cam moves to its restored cam set position immediately after starting synchronous control when the restored cam set position is different from the set position at synchronous control start.

■Cam set position restoration allowable movement setting value

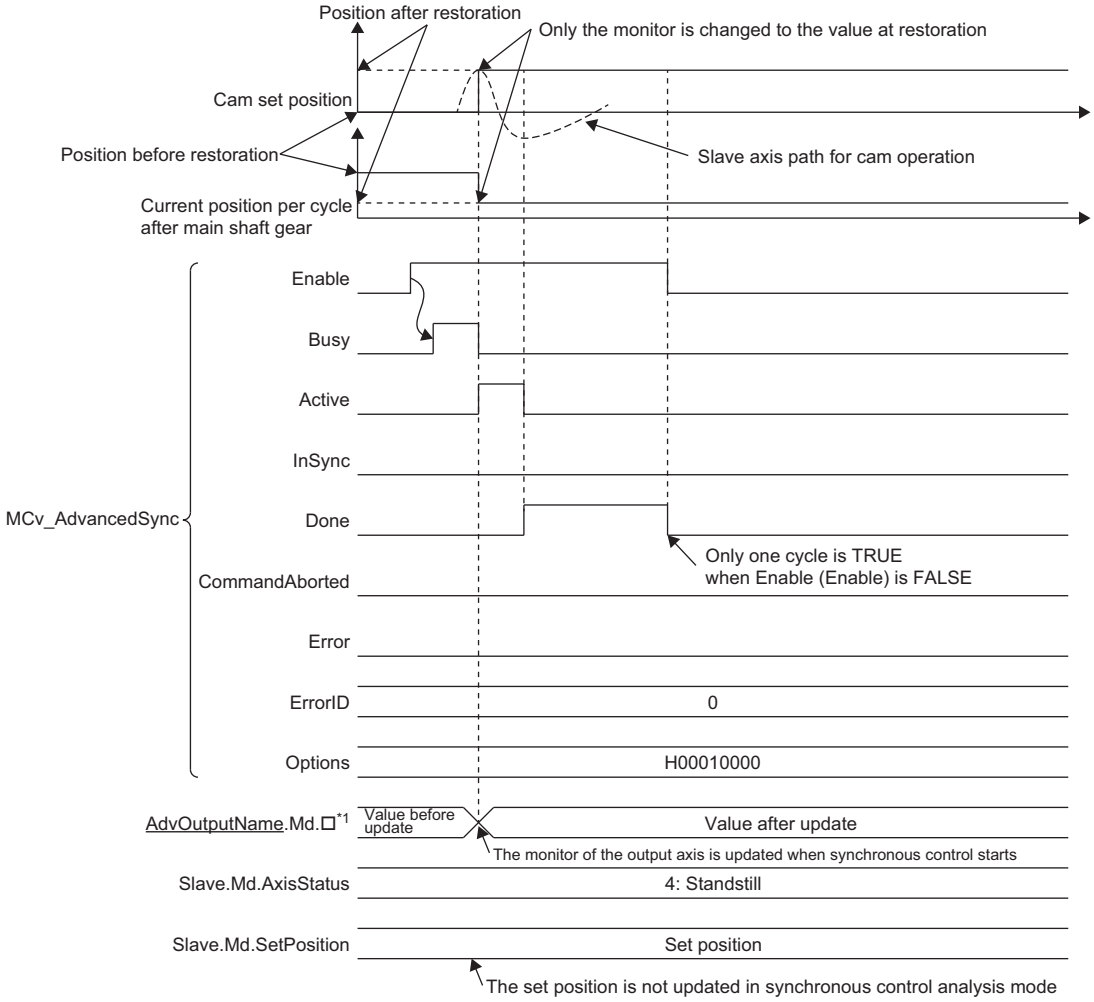
When MCv_AdvancedSync (Advanced Synchronous Control) is started, if the difference between the restored cam set position and the set position of the slave axis is larger than the cam set position restoration allowable movement setting value, Advanced Synchronous Control Restoration Disabled (error code: 1B24H) occurs, and synchronous control cannot start. When using cam set position restoration, before starting MCv_AdvancedSync (Advanced Synchronous Control), calculate the corresponding cam set position with MCv_AdvPositionPerCycleCalc (Advanced Synchronous Control Current Position Per Cycle Calculation), MCv_AdvCamSetPositionCalc (Advanced Synchronous Control Cam Set Position Calculation), or synchronous control analysis mode. Start synchronous control after positioning to the correct cam set position.



Synchronous control analysis mode

When MCv_AdvancedSync (Advanced Synchronous Control) is started, the synchronous control analysis mode only performs an analysis on synchronous control restoration. This mode is used to check the synchronous position of the output axis for the synchronous position alignment before starting MCv_AdvancedSync (Advanced Synchronous Control). After starting MCv_AdvancedSync (Advanced Synchronous Control), when synchronous control analysis mode setting (Options (Options): Bit 16) of MCv_AdvancedSync (Advanced Synchronous Control) is "TRUE (Enabled)", operation is performed in synchronous control analysis mode.
When analysis is completed, Execution completion (Done) of MCv_AdvancedSync (Advanced Synchronous Control) turns to "TRUE", and the Output axis monitor data (AdvOutputName.Md.☐) that are not in Synchronization status (AdvOutputName.Md.SyncStatus) are all updated. The following Output axis monitor data (AdvOutputName.Md.☐) are also updated to the restored values. In this case, synchronous control analysis mode setting (Options (Options): Bit 16) of MCv_AdvancedSync (Advanced Synchronous Control) will not turn to "FALSE (Disabled)". When starting synchronous control without using the synchronous control analysis mode, turn synchronous control analysis mode setting (Options (Options): Bit 16) of MCv_AdvancedSync (Advanced Synchronous Control) to "FALSE (Disabled)".

Output axis monitor data (AdvOutputName.Md.☐)
• Current position after composite main shaft gear (AdvOutputName.Md.Cam.MasterCompositeGearSetPosition) • Current position per cycle after main shaft gear (AdvOutputName.Md.Cam.MasterGearPositionPerCycle) • Current position per cycle after auxiliary shaft gear (AdvOutputName.Md.Cam.AuxGearPositionPerCycle) • Current position per cycle (AdvOutputName.Md.Cam.PositionPerCycle) • Cam reference position (AdvOutputName.Md.ReferenceSetPosition) • Cam set position (AdvOutputName.Md.Cam.SetPosition)



Processing in synchronous control analysis mode

In synchronous control analysis mode, unlike normal restoration, processing is executed until monitor restoration.

Synchronous control analysis mode will not operate if the Axis status (AxisName.Md.AxisStatus) of the Slave axis (Slave) of MCv_AdvancedSync (Advanced synchronous control) is other than "4: Standby (Standstill)".
When MCv_AdvancedSync (Advanced synchronous control) is started in synchronous control analysis mode, if the cam current position per cycle cannot be restored, Advanced Synchronous Control Restoration Disabled (error code: 1B24H) occurs.

Timing chart of synchronous control analysis mode

*1 Synchronization status (AdvOutputName.Md.SyncStatus) of the Output axis monitor data remains "0: Not synchronizing" and is not updated.

Variables related to synchronous control initial position

Synchronous control initial position parameter (AdvOutputName.Pr.Restore.)

Variable name	Name	Import*1	Data type*1	Setting value	Initial value
MasterGearPositionPerCycleMethod	Setting method of current position per cycle after main shaft gear	At start	INT (MC_GEAR_RESTORE_METHOD)	• 0: Previous value (PreviousPosition) • 1: Current position per cycle after main shaft gear (initial setting) (InitialGearPositionPerCycle) • 2: Calculate from input axis (CalculateFromInputAxis)	0: Previous value (PreviousPosition)
AuxGearPositionPerCycleMethod	Setting method of current position per cycle after auxiliary shaft gear		INT (MC_GEAR_RESTORE_METHOD)	• 0: Previous value (PreviousPosition) • 1: Current position per cycle after auxiliary shaft gear (initial setting) (InitialGearPositionPerCycle) • 2: Calculate from input axis (CalculateFromInputAxis)	0: Previous value (PreviousPosition)
PositionRestorationObject	Cam axis position restoration object		INT (MC_CAM_RESTORE_METHOD)	• 0: Current position per cycle restoration (RestorePositionPerCycle) • 1: Cam reference position restoration (RestoreReferenceSetPosition) • 2: Cam set position restoration (RestoreCamSetPosition)	0: Current position per cycle restoration (RestorePositionPerCycle)
ReferenceSetPositionMethod	Setting method of cam reference position		INT (MC_CAM_REFERENCE_METHOD)	• 0: Previous value (PreviousPosition) • 1: Cam reference position (initial setting) (InitialReferenceSetPosition) • 2: Cam set position (CamSetPosition)	0: Previous value (PreviousPosition)

MasterGearInitialPositionPerCycle	Current position per cycle after main shaft gear (initial setting)		LREAL	0.0 to 2147483647.0	0.0
AuxGearInitialPositionPerCycle	Current position per cycle after auxiliary shaft gear (initial setting)		LREAL	0.0 to 2147483647.0	0.0
InitialReferenceSetPosition	Cam reference position (initial setting)		LREAL	-10000000000.0 to 10000000000.0	0.0
InitialPositionPerCycle	Current position per cycle (initial setting)		LREAL	0.0 to 2147483646.0	0.0
RestorationAllowablePosition	Cam set position restoration: Allowable movement amount setting		DWORD (UDINT)	0 to 2147483647 [pulses]	25600

*1 For details on importing and data types, refer to "List of Variables" in the following manual.
MELSEC MX Controller MX-R Model Programming Manual

■Setting method of current position per cycle after main shaft gear (AdvOutputName.Pr.Restore.MasterGearPositionPerCycleMethod)

Select the setting method for current position per cycle after main shaft gear (AdvOutputName.Md.Cam.MasterGearPositionPerCycle) when starting MCv_AdvancedSync (Advanced Synchronous Control).

Setting value	Description
0: Previous value (PreviousPosition)	The current position per cycle after main shaft gear from the previous synchronous control is stored.
1: Current position per cycle after main shaft gear (initial setting) (InitialGearPositionPerCycle)	The value set in Current position per cycle after main shaft gear (initial setting) (AdvOutputName.Pr.Restore.MasterGearInitialPositionPerCycle) is stored.
2: Calculate from input axis (CalculateFromInputAxis)	The value calculated based on the current position after composite main shaft gear is stored.

■Setting method of current position per cycle after auxiliary shaft gear (AdvOutputName.Pr.Restore.AuxGearPositionPerCycleMethod)

Select the setting method for current position per cycle after auxiliary shaft gear (AdvOutputName.Md.Cam.AuxGearPositionPerCycle) when starting MCv_AdvancedSync (Advanced Synchronous Control).

Setting value	Description
0: Previous value (PreviousPosition)	The current position per cycle after auxiliary shaft gear from the previous synchronous control is stored.
1: Current position per cycle after auxiliary shaft gear (initial setting) (InitialGearPositionPerCycle)	The value set in Current position per cycle after auxiliary shaft gear (initial setting) (AdvOutputName.Pr.Restore.AuxGearInitialPositionPerCycle) is stored.
2: Calculate from input axis (CalculateFromInputAxis)	The value calculated based on the current position of the auxiliary shaft is stored.

■Cam axis position restoration object (AdvOutputName.Pr.Restore.PositionRestorationObject)

Select "Current position per cycle", "Cam reference position", or "Cam set position" to be restored when synchronous control is started.

Setting value	Description
0: Current position per cycle restoration (RestorePositionPerCycle)	The current position per cycle is restored from "Cam reference position" and "Cam set position".
1: Cam reference position restoration (RestoreReferenceSetPosition)	The cam reference position is restored from "Current position per cycle" and "Cam set position".
2: Cam set position restoration (RestoreCamSetPosition)	The cam set position is restored from "Current position per cycle" and "Cam reference position".

■Setting method of cam reference position (AdvOutputName.Pr.Restore.ReferenceSetPositionMethod)

Set the setting method for the cam reference position to be used for restoration when Cam axis position restoration object (AdvOutputName.Pr.Restore.PositionRestorationObject) is set to "0: Current position per cycle restoration (RestorePositionPerCycle)" or "2: Cam set position restoration (RestoreCamSetPosition)".

Setting value	Description
0: Previous value (PreviousPosition)	The cam reference position from the previous synchronous control is stored. The set position is stored when the cam reference position from the previous synchronous control is not saved.
1: Cam reference position (initial setting) (InitialReferenceSetPosition)	The value set in Cam reference position (initial setting) (AdvOutputName.Pr.Restore.InitialReferenceSetPosition) is stored.
2: Cam set position (CamSetPosition)	The value set in Set position (AxisName.Md.SetPosition) of the slave axis is stored.

■Setting method of current position per cycle (AdvOutputName.Pr.Restore.PositionPerCycleMethod)

Set the setting method for the current position per cycle to be used for restoration when Cam axis position restoration object (AdvOutputName.Pr.Restore.PositionRestorationObject) is set to "1: Cam reference position restoration (RestorePositionPerCycle)" or "2: Cam set position restoration (RestoreCamSetPosition)".

Setting value	Description
0: Previous value (PreviousPosition)	The current position per cycle from the previous synchronous control is stored as is.
1: Current position per cycle (initial setting) (InitialPositionPerCycle)	The value set in Current position per cycle (initial setting) (AdvOutputName.Pr.Restore.InitialPositionPerCycle) is stored.
2: Current position per cycle after main shaft gear (MasterGearPositionPerCycle)	Current position per cycle after main shaft gear (AdvOutputName.Md.Cam.MasterGearPositionPerCycle) is stored.
3: Current position per cycle after auxiliary shaft gear (AuxGearPositionPerCycle)	Current position per cycle after auxiliary shaft gear (AdvOutputName.Md.Cam.AuxGearPositionPerCycle) is stored.

■Current position per cycle after main shaft gear (initial setting) (AdvOutputName.Pr.Restore.MasterGearInitialPositionPerCycle)

Set the initial setting value of the current position per cycle after main shaft gear when Setting method of current position per cycle after main shaft gear (AdvOutputName.Pr.Restore.MasterGearPositionPerCycleMethod) is set to "1: Current position per cycle after main shaft gear (initial setting) (InitialGearPositionPerCycle)". The unit settings are in units of the input axis set to Master axis (Master) of MCv_AdvancedSync (Advanced Synchronous Control).
Set within the range from "0.0 to (Length per cycle - 0.00001)".

■Current position per cycle after auxiliary shaft gear (initial setting) (AdvOutputName.Pr.Restore.AuxGearInitialPositionPerCycle)

Set the initial setting value of the current position per cycle after auxiliary shaft gear when Setting method of current position per cycle after auxiliary shaft gear (AdvOutputName.Pr.Restore.AuxGearPositionPerCycleMethod) is set to "1: Current position per cycle after auxiliary shaft gear (initial setting) (InitialGearPositionPerCycle)".
The unit settings are in units of the input axis set to Master axis (Master) of MCv_AdvancedSync (Advanced Synchronous Control).
Set within the range from "0.0 to (Length per cycle - 0.00001)".

■Cam reference position (initial setting) (AdvOutputName.Pr.Restore.InitialReferenceSetPosition)

When Setting method of cam reference position (AdvOutputName.Pr.Restore.ReferenceSetPositionMethod) is set to "1: Cam reference position (initial setting) (InitialReferenceSetPosition)", set the initial setting value of the cam reference position in the units of the axis set to the output axis Axis information (AdvOutputName.Axis).

■Current position per cycle (initial setting) (AdvOutputName.Pr.Restore.InitialPositionPerCycle)

Set a value according to the setting for Cam axis position restoration object (AdvOutputName.Pr.Restore.PositionRestorationObject).
The unit settings are in units of the input axis set to Master axis (Master) of MCv_AdvancedSync (Advanced Synchronous Control).
Set within the range from "0.0 to (Length per cycle - 0.00001)".

Cam axis position restoration object (AdvOutputName.Pr.Restore.PositionRestorationObject)	Description
0: Current position per cycle restoration (RestorePositionPerCycle)	Set the starting point for search processing to restore the current position per cycle. Set to restore the position on the return path of a two-way operation cam pattern. For details on search processing, refer to the following. ☞ Page 997 Current position per cycle restoration
1: Cam reference position restoration (RestoreReferenceSetPosition)	Set the initial setting value for the current position per cycle when Setting method of current position per cycle (AdvOutputName.Pr.Restore.PositionPerCycleMethod) is set to "1: Current position per cycle (initial setting) (InitialPositionPerCycle)".
2: Cam set position restoration (RestoreCamSetPosition)	

■Cam set position restoration: Allowable movement amount setting (AdvOutputName.Pr.Restore.RestorationAllowablePosition)

Set the allowable value of the difference between the restored cam set position and the set position in units of the servo command value of the output axis when Cam axis position restoration object (AdvOutputName.Pr.Restore.PositionRestorationObject) is set to "2: Cam set position restoration (RestoreCamSetPosition). If the setting value is large, a rapid operation may occur when starting synchronous control.

Point

The MR-J5(W)-G servo parameter "In-position range (PA10)" initial value (25600) is set as the initial value.

Precautions

Accuracy at restoration

Since accuracy of the advanced synchronous control output axis is guaranteed for up to 5 decimal places, the calculations during restoration are also performed with this accuracy.
Therefore, depending on the position of the output axis, the fourth decimal place of the current position of the output axis may move slightly, but this does not result in position displacement. Depending on parameter settings and programs, the axis may move significantly at restoration. For safety reasons, check the movement amount by restoration in synchronous control analysis mode before starting synchronous control.

Current position per cycle restoration for coordinate data

- When the last point of cam data is larger than the length per cycle, the entire range of cam data is searched regardless of the set value of the length per cycle, which may result in restoration to a position different from the path of synchronous control.
- When the last point of cam data is smaller than the length per cycle, the current position per cycle may become larger than the length per cycle depending on the relationship between the cam set position and the cam reference position. When using the coordinate data, match the last point of cam data with the length per cycle.

Restoration time of the current position per cycle

The current position per cycle restoration completion time varies depending on the resolution, coordinate number, and the restoration settings.
An approximate guide of the restoration time is shown below.

■Cam data (section interpolation/spline interpolation)/rotary cutter

Resolution/Coordinate number	256			65535		
Operation cycle [ms]	**0.25**	**0.5**	**1.0**	**0.25**	**0.5**	**1.0**
Restoration time [ms]	0.4	0.3	0.4	5.2	4.7	4.5

■Cam data (linear interpolation)

Resolution/Coordinate number	256			65535		
Operation cycle [ms]	**0.25**	**0.5**	**1.0**	**0.25**	**0.5**	**1.0**
Restoration time [ms]	0.4	0.3	0.4	5.8	5.2	4.9

33.6 Cam Position Calculation Function

The cam position calculation function calculates the current position per cycle and the cam set position with the following motion control FBs.

- MCv_AdvPositionPerCycleCalc (Advanced Synchronous Control Current Position Per Cycle Calculation)
- MCv_AdvCamSetPositionCalc (Advanced Synchronous Control Cam Set Position Calculation)

This function is used to calculate the synchronous position of the output axis for the synchronous position alignment before starting advanced synchronous control.

With the synchronous control analysis mode, the output axis whose position is to be calculated must be in the standby status (Axis status (AxisName.Md.AxisStatus) is "4: Standby (Standstill)"). However, with the cam position calculation function, the calculation can be executed regardless of the output axis status, thus it is used to calculate the synchronous position of the next control in advance while the output axis is operating.

Control details

Setting the ring counter

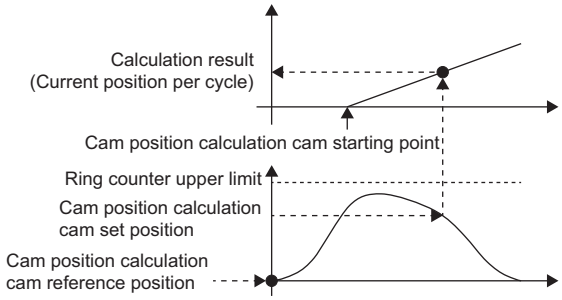
Set the Ring counter upper limit value (AxisName.PrConst.RingCount_UpperValue) of the output axis to the Ring counter upper limit (RingCountUpperValue) of MCv_AdvCamSetPositionCalc (Advanced Synchronous Control Cam Set Position Calculation) or MCv_AdvPositionPerCycleCalc (Advanced Synchronous Control Current Position Per Cycle Calculation).

When a value other than "0.0" is set to MCv_AdvCamSetPositionCalc (Advanced Synchronous Control Cam Set Position Calculation) or MCv_AdvPositionPerCycleCalc (Advanced Synchronous Control Current Position Per Cycle Calculation), the ring counter lower limit is calculated as "0.0".

Setting the cam starting point

- Set the cam position calculation Cam starting point (StartingPoint) of MCv_AdvCamSetPositionCalc (Advanced Synchronous Control Cam Set Position Calculation) or MCv_AdvPositionPerCycleCalc (Advanced Synchronous Control Current Position Per Cycle Calculation) when taking into account the cam starting point for calculations.
- The cam position calculation Cam starting point (StartingPoint) sets the position to start cam data in resolution. This is valid only in the following cases.
  · When the Interpolation method specification (Interpolate) of the operation profile data is "1: Section interpolation" or "2: Spline interpolation"
  · When the data type is set to "Rotary cutter"

Current position per cycle calculation (MCv_AdvPositionPerCycleCalc)



When Execution command (Execute) is changed from FALSE to TRUE, the current position per cycle is calculated based on the cam position calculation Cam reference position (ReferenceSetPosition) and the cam position calculation Cam set position (SetPosition) from the cam data. The calculation result is output to the Calculation result (CalculationResult).

■When the ring counter upper limit is set

The cam position calculation cam reference position and the cam position calculation cam set position are rounded to the ring counter upper limit before calculation when the cam position calculation Ring counter upper limit (RingCountUpperValue) is set.

■When the cam starting point is set

The cam starting point is taken into account for the current position per cycle calculation when the cam position calculation Cam starting point (StartingPoint) is set.

■Searching the current position per cycle

When calculating the current position per cycle from the cam data, the position corresponding to the cam position calculation cam set position is searched from the cam data based on the position set in the cam position calculation Current position per cycle (PositionPerCycle).

The cam position calculation cam set position is searched with the following procedure.

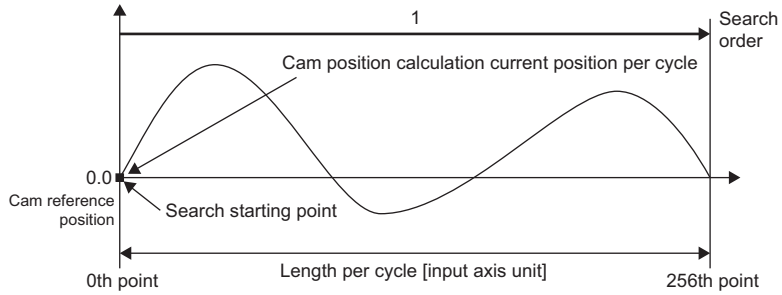
- Cam data (when the Interpolation method specification (Interpolate) of the operation profile data is "1: Section interpolation" or "2: Spline interpolation", or when the data type is set to "Rotary cutter")

■When "nth point of cam data ≤ Cam position calculation Current position per cycle (PositionPerCycle) < Cam data n + First point"

• The position corresponding to the cam position calculation Cam set position (SetPosition) is searched from the nth point of cam data.

■When the cam position calculation current position per cycle (PositionPerCycle) is in the middle of cam data and there is no corresponding position until the last point of cam data

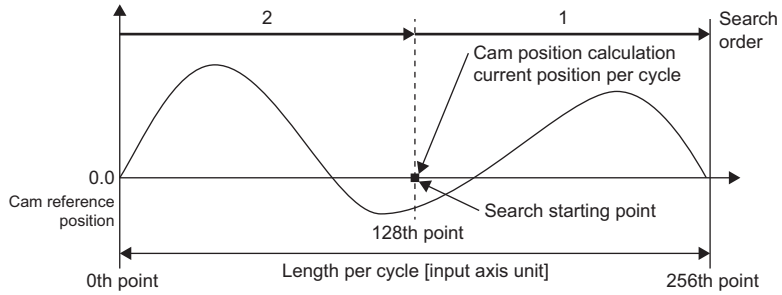
• The search returns to the 0th point of cam data and searches to the position where the search started.



■When there is no corresponding position after searching the entire range of cam data

• For a two-way cam, Unable to Calculate Cam Position Under Advanced Synchronous Control (error code: 1BCEH) occurs.

• For a feed cam, the cam position calculation Cam set position (SetPosition) is calculated from the stroke difference, and the entire range is re-searched from the 0th point. When there is no corresponding position even after re-searching, Unable to Calculate Cam Position Under Advanced Synchronous Control (error code: 1BCEH) occurs.

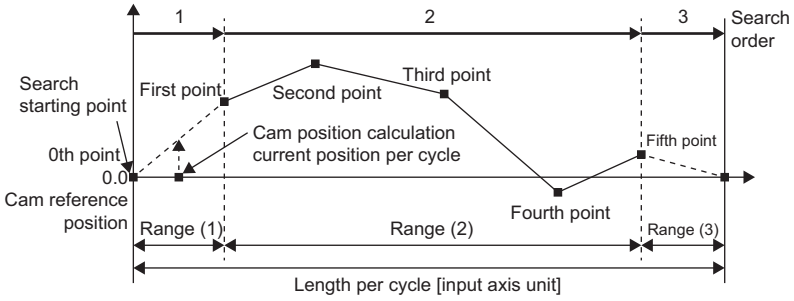


(Example 1)

When the cam position calculation Current position per cycle (PositionPerCycle) corresponds to the 0th point of cam data

(Example 2)

When the cam position calculation Current position per cycle (PositionPerCycle) corresponds to the 128th point of cam data



- Cam data (when the Interpolation method specification (Interpolate) of the operation profile data is "0: Linear interpolation")

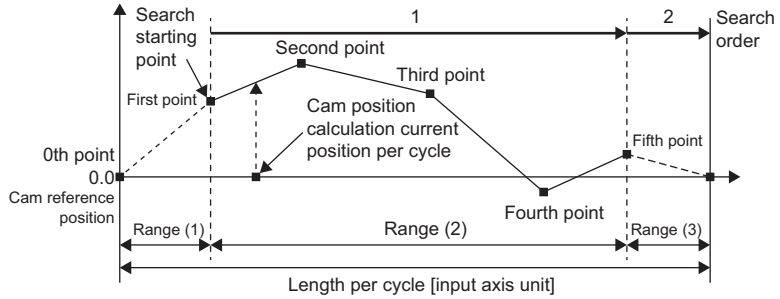
■Range before the first point of cam data

- When the first point of cam data is larger than 0 and "Cam position calculation Current position per cycle (PositionPerCycle) < First point of cam data" is satisfied, the position corresponding to the cam position calculation Cam set position (SetPosition) is searched from the range before the first point of cam data.
- When there is no corresponding position in range (1), range (2) is searched. When there is also no corresponding position in range (2), range (3) is searched.
- When there is no corresponding position after searching ranges (1) to (3), Unable to Calculate Cam Position Under Advanced Synchronous Control (error code: 1BCEH) occurs for a two-way cam. For a feed cam, the cam position calculation Cam set position (SetPosition) is calculated from the stroke difference, and the entire range is re-searched from the 0th point. When there is no corresponding position even after re-searching, Unable to Calculate Cam Position Under Advanced Synchronous Control (error code: 1BCEH) occurs.

(Example)

When the cam position calculation current position per cycle is before the first point of cam data

* Search from range (1).

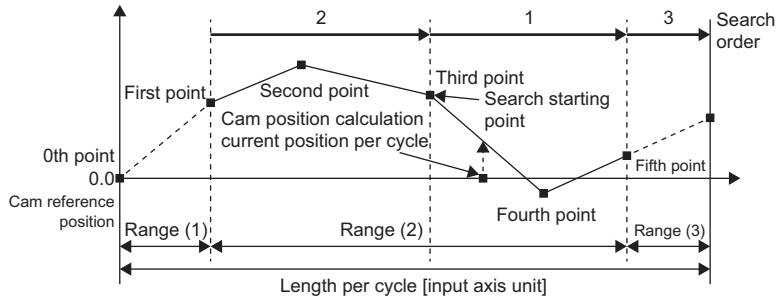


* When there is no corresponding position in range (1), search in order from the first point of cam data in range (2).

■Within the cam data range

- When "Cam position calculation Current position per cycle (PositionPerCycle) < Last point of cam data" is satisfied, the position corresponding to the cam position calculation Cam set position (SetPosition) is searched from within the cam data range.
- When "nth point of cam data ≤ Cam position calculation Current position per cycle < Cam data n + First point" is satisfied, the position corresponding to the cam position calculation Cam set position is searched from the nth point of cam data.
- When the cam position calculation current position per cycle is in the middle of cam data and there is no corresponding position until the last point of cam data, the search returns to the first point of cam data and searches to the position where the search started.
- When there is no corresponding position in range (1), range (2) is searched. When there is also no corresponding position in range (2), range (3) is searched.
- When there is no corresponding position after searching ranges (2) and (3), Unable to Calculate Cam Position Under Advanced Synchronous Control (error code: 1BCEH) occurs for a two-way cam.
- For a feed cam, the cam position calculation Cam set position is calculated from the stroke difference, and the entire range is re-searched from the 0th point. When there is no corresponding position even after re-searching, Unable to Calculate Cam Position Under Advanced Synchronous Control (error code: 1BCEH) occurs.

(Example 1)



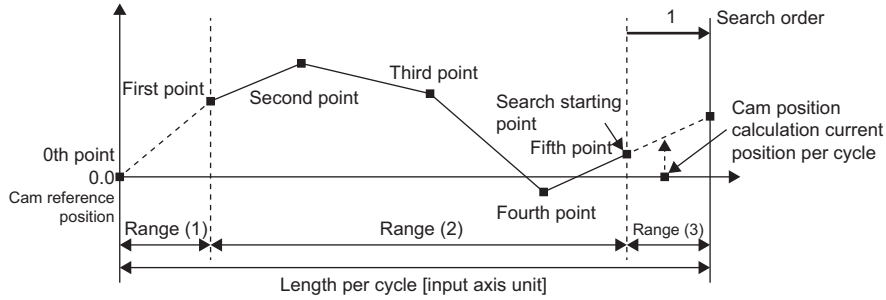
When the cam position calculation current position per cycle corresponds to the first point of cam data

❶ Search in order from cam data first point to second point, second point to third point, and up to fourth point to fifth point (last point).
❷ If there is no corresponding position until the last point of cam data, search from range (3).

(Example 2)

When the cam position calculation current position per cycle corresponds to the third point of cam data

❶ Search in order from cam data third point to fourth point, fourth point to fifth point (last point).
❷ If there is no corresponding position until the last point of cam data, search from the first point of cam data.
❸ If there is no corresponding position in the cam data first point to second point and second point to third point, search from range (3).



■Range from the cam data last point to the length per cycle

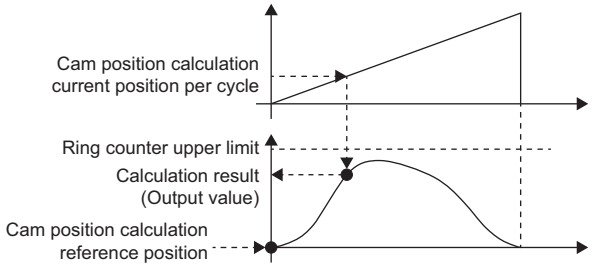
When "Last point of cam data ≤ Cam position calculation Current position per cycle (PositionPerCycle) < Length per cycle" is satisfied, the position corresponding to the cam position calculation Cam set position (MCv_AdvPositionPerCycleCalc.SetPosition) is searched from the last point of cam data. When there is no corresponding position after searching range (3), Unable to Calculate Cam Position Under Advanced Synchronous Control (error code: 1BCEH) occurs for a two-way cam.

For a feed cam, the cam position calculation Cam set position is calculated from the stroke difference, and the entire range is re-searched from the 0th point. When there is no corresponding position even after re-searching, Unable to Calculate Cam Position Under Advanced Synchronous Control (error code: 1BCEH) occurs.

(Example)

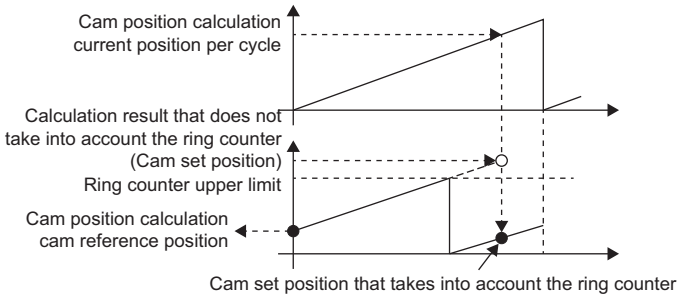
When the cam position calculation current position per cycle corresponds to the last point of cam data

❶ Search from range (3).



Cam set position calculation (MCv_AdvCamSetPositionCalc)

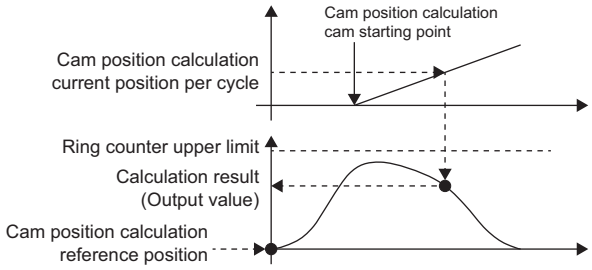
When Execution command (Execute) is changed from FALSE to TRUE, the cam set position is calculated based on the cam position calculation Current position per cycle (PositionPerCycle) and the cam position calculation Cam reference position (ReferenceSetPosition). The calculation result is output to the Calculation result (CalculationResult).



■When the ring counter upper limit is set

The calculation result is rounded to a value that takes into account the ring counter when the cam position calculation Ring counter upper limit (RingCountUpperValue) is set.

- When the calculation result does not exceed the ring counter upper limit



- When the calculation result exceeds the ring counter upper limit

■When the cam starting point is set

The cam set position is calculated with the current position per cycle that takes into account the cam starting point when the cam position calculation Cam starting point (StartingPoint) is set.

Precautions

- Set the cam data to expand automatically in the expand setting in advance, or send it to the open area with MC_CamTableSelect (Cam Table Selection) for use.
- Apply the calculation results of the Current position per cycle calculation (MCv_AdvPositionPerCycleCalc) and the Cam set position calculation (MCv_AdvCamSetPositionCalc) only to MCv_AdvancedSync (Advanced Synchronous Control). If they are applied to synchronous control FBs (such as MC_CamIn) other than MCv_AdvancedSync (Advanced Synchronous Control), the calculation result and the actual operation will not match.
- The current position per cycle calculation of the coordinate data may result as follows depending on the length per cycle of the last point of cam data.

Last point of cam data	Description
Larger than the length per cycle	The entire range of cam data is searched regardless of the set value of the length per cycle, which may result in a different calculation result from the path of synchronous control.
Smaller than the length per cycle	The current value per cycle may become larger than the length per cycle depending on the relationship between the cam set position and the cam reference position. When using the coordinate data, it is recommended to match the last point of cam data with the length per cycle.

33.7 Application Function

Phase compensation function

In synchronous control, a slight phase delay occurs between the input axis (real drive axis, real encoder axis, virtual encoder axis) and the output axis motor shaft end. The phase compensation function compensates in this case so that the phase does not deviate.

Phase compensation can be set for the input and output axes. It is possible to compensate the delay time peculiar to the system based on the axis type on the input axis side. It is also possible to compensate the delay time equivalent to the position deviation for each drive unit on the output axis side.

Phase compensation on delay time of the input axis

Set delay time peculiar to the system in the phase compensation advance time of the input axis (AdvInputName.Pr.PhaseCompensationAdvanceTime). For reference, the delay time peculiar to a system with the MR-J5(W)-G connected to the drive unit is shown.

As the delay time will change depending on the actual equipment configuration, make adjustments from the reference values below.

■Delay time peculiar to the system for a real drive axis (MR-J5(W)-G)*1

The delay time depends on the setting of Data source selection (AdvInputName.PrConst.SourceValue) as follows.

- When set to "1: Set Value (mcSetValue)" or "101: Latest Set Value (mcLatestSetValue)"
  · Delay time: 0 [μs]
- When set to "2: Actual Value (mcActualValue)" or "102: Latest Actual Value (mcLatestActualValue)"
  The delay time is calculated using the following formula.

0: Response preferred method (EmphasisResponse)
Operation cycle × 5 + 750 [μs]

*1 The delay time of "1: Set Value (mcSetValue)" and "2: Actual Value (mcActualValue)" is the delay time of "101: Latest Set Value (mcLatestSetValue)" and "102: Latest Actual Value (mcLatestActualValue)" + one operation cycle.
When compensating a delay, set the value obtained by adding one operation cycle to the delay time peculiar to the system as the compensation time.

■Delay time peculiar to the system for a real encoder axis*1

The delay time is calculated using the following formula regardless of the setting of Data source selection (AdvInputName.PrConst.SourceValue).

0: Response preferred method (EmphasisResponse)
Operation cycle × 5 + 750 [μs]

*1 The delay time of "1: Set Value (mcSetValue)" and "2: Actual Value (mcActualValue)" is the delay time of "101: Latest Set Value (mcLatestSetValue)" and "102: Latest Actual Value (mcLatestActualValue)" + one operation cycle.
When compensating a delay, set the value obtained by adding one operation cycle to the delay time peculiar to the system as the compensation time.

■Delay time peculiar to the system for a virtual encoder axis

The delay time is calculated using the following formula.

• Delay time peculiar to the input target + Virtual encoder input value refresh time [μs]

Ex.

In the following cases

Example	Description
1	■When setting the MR-J5(W)-G object data_PosActualValue (AxisName.Md.Io_PosActualValue) to the virtual encoder axis object data (AxisName.PrConst.SlaveObject.PosActualValue) settings • Delay time peculiar to the system for a real drive axis*1 + Refresh cycle of AxisName.Md.Io_PosActualValue (one operation cycle)
2	■When updating the virtual encoder axis encoder input value (AxisName.Cd.Encoder_InputValue) with a counter value of another unit in an ST program • Delay time peculiar to the counter + ST program scan time

*1 "102: Latest Actual Value (mcLatestActualValue)" of Data source selection (AdvInputName.PrConst.SourceValue)

■Delay time peculiar to the system for a virtual drive axis/virtual linked axis

The delay time is "0 [μs]" regardless of the setting of Data source selection (AdvInputName.PrConst.SourceValue).

Phase compensation of delay time of the output axis

Set the delay time equivalent to the position deviation of the drive unit in the output axis phase compensation advance time (AdvOutputName.Pr.Cam.PhaseCompensationAdvancedTime). The delay time equivalent to position deviation of the drive unit is calculated using the following formula.

When the MR-J5(W)-G is used: Delay time [μs] = 1000000 ÷ Servo parameter "Model loop gain (PB07)"

When the servo parameter "Feed forward gain (PB04)" is set, the delay time is set to a smaller value than the value shown above.

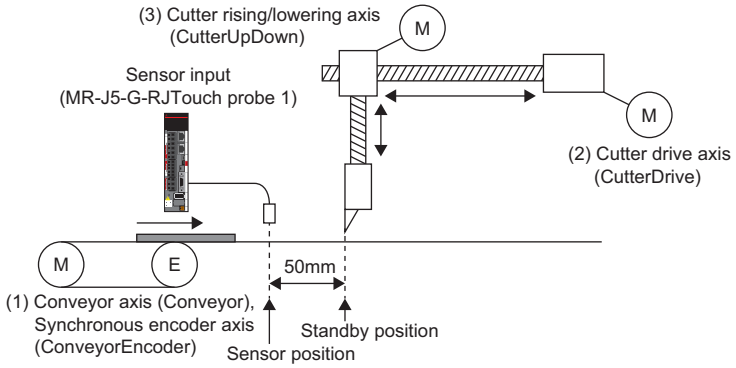
The model loop gain will change when "Gain adjustment mode selection (PA08.0)" is set to "1: Auto tuning mode 1" or "2: Auto tuning mode 2". For axes executing phase compensation, set "3: Manual mode" or "0: 2 gain adjustment mode 1 (interpolation mode)" to prevent model loop gain from changing.

Setting example

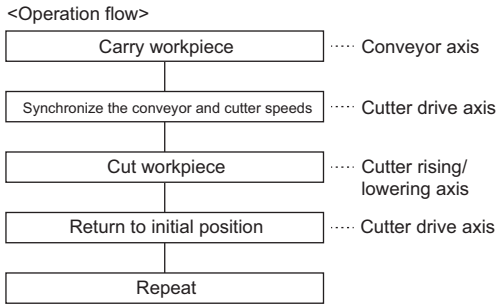
When the output axis is synchronized with a real encoder axis, set the phase compensation advance time as follows.

- When model loop gain of the output axis is 80

Setting item		Setting value
Input axis	Phase compensation advance time (AdvInputName.Pr.PhaseCompensationAdvanceTime)	Set the delay time peculiar to the system for a real encoder axis. Refer to the following for delay time peculiar to the system for a real encoder axis. ☞ Page 1016 Delay time peculiar to the system for a real encoder axis*1
Output axis	Phase compensation advance time (AdvOutputName.Pr.Cam.PhaseCompensationAdvancedTime)	1000000 ÷ 80 = 12500 [μs]



When the slave axis set velocity overshoots or undershoots during acceleration/deceleration, increase the phase compensation time constant.

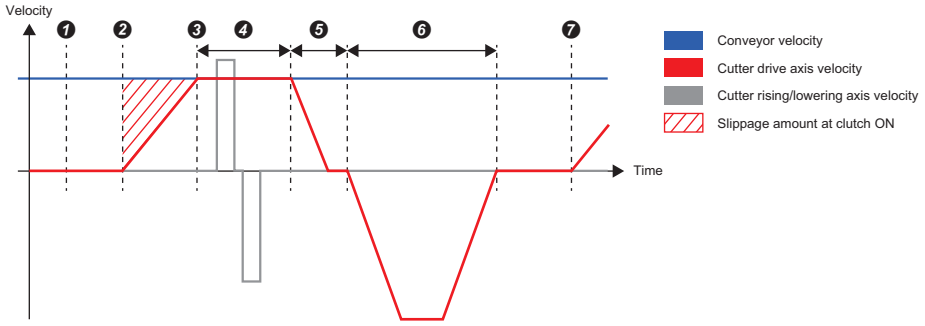


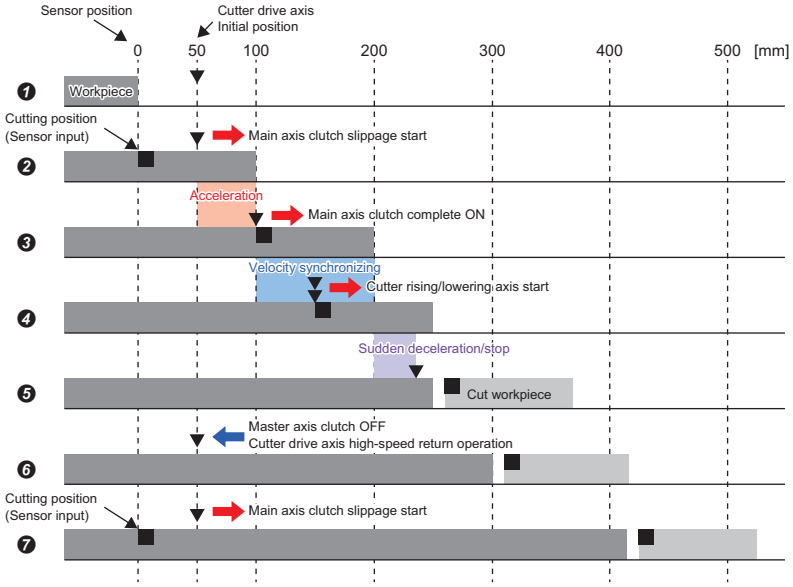
33.8 Example Programs

Example programs for advanced synchronous control are shown below.

Flying shear

This section describes the example programs and how to use clutch operation that uses an advanced synchronous control FB sensor input based on a flying shear system.





Setting item	(1) Conveyor axis	(1) Synchronous encoder axis	(2) Cutter drive axis	(3) Vertical cutter axis	Virtual drive axis for cutter drive axis high-speed return operation
Axis name	Conveyor	ConveyorEncoder	CutterDrive	CutterUpDown	CutterDriveBack
Axis type	Real drive axis	Real encoder axis	Real drive axis	Real drive axis	Virtual drive axis
Real encoder axis type setting	—	Via drive unit	—	—	—
Station address	192.168.3.1	192.168.3.1	192.168.3.2	192.168.3.3	—
Position command unit	μm	μm	μm	μm	μm
Velocity command unit	U/min	U/min	U/min	U/min	U/min

Operation overview

1. Advanced synchronous control FB starts with the conveyor axis as the "input axis" and the cutter drive axis as the "output axis".
2. The sensor input starts the clutch ON operation of the main shaft clutch.
3. After smoothing is complete with main shaft clutch ON, the speed of the conveyor axis and the cutter drive axis is the same.
4. The vertical cutter axis is started by positioning control when the speed of the conveyor axis and the cutter drive axis becomes the same, and it cuts the workpiece.
5. After completing the cutting of the workpiece (completion of positioning control of the vertical cutter axis), the main shaft clutch turns off and the cutter drive axis is stopped.
6. After stopping the cutter drive axis, positioning of the virtual drive axis that is set as the auxiliary shaft returns the cutter drive axis to its initial position.
7. Steps 2 to 6 are repeated.

Parameter settings

■Setting of the real encoder axis (conveyor axis) to be used as the input axis of advanced synchronous control

In the "CC-Link IE TSN Configuration" window under Network Configuration Settings in GX Works3, add the required objects for the real encoder axis in the "PDO Mapping Setting" of the MR-J5(W)-G(-RJ) that uses a synchronous encoder in [PDO Mapping Setting] ⇨ "PDO Mapping Setting" window.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [Module Parameter (Port 1/2: CC-Link IE TSN)] ⇨ [Module Parameter (CC-Link IE TSN)] ⇨ [Basic Settings] ⇨ [Network Configuration Settings]

- RPDO mapping: None
- TPDO mapping

Index	Sub-index	Entry name	Data type
2d36	00	Scale cycle counter	UNSIGNED32
2d37	00	Scale ABS counter	INTEGER32
2d3c	00	Scale measurement encoder recept	UNSIGNED32

Also, when using a synchronous encoder, the scale measurement function must be enabled in MR-J5(W)-G(-RJ). Set the following servo parameter.

No.	Symbol	Name	Setting value
PA22.3	**PCS	Scale measurement function selection	Set 1 or 2. • 1: Use with absolute position detection system • 2: Use with incremental system

For the settings of the real encoder axis, refer to the following.

☞ Page 455 Real encoder axis

■Setting of the sensor input (MR-J5(W)-G(-RJ) touch probe function)

In the "CC-Link IE TSN Configuration" window under Network Configuration Settings in GX Works3, add the required objects for the touch probe function in the "PDO Mapping Setting" of the MR-J5(W)-G(-RJ) that uses a touch probe in [PDO Mapping Setting] ⇨ "PDO Mapping Setting" window.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [Module Parameter (Port 1/2: CC-Link IE TSN)] ⇨ [Module Parameter (CC-Link IE TSN)] ⇨ [Basic Settings] ⇨ [Network Configuration Settings]

- RPDO mapping

Index	Sub-index	Entry name	Data type
60b8	00	Touch probe function	UNSIGNED16

- TPDO mapping

Index	Sub-index	Entry name	Data type
60b9	00	Touch probe status	UNSIGNED16
60d1	00	Touch probe time stamp 1 positiv	UNSIGNED32
60d2	00	Touch probe time stamp 1 negativ	UNSIGNED32

In the network label settings in GX Works3, make the Touch probe function set in the RPDO mapping and TPDO mapping into a label.

Navigation window ⇨ [Parameter] ⇨ Controller ⇨ [Module Parameter (Port 1/2: CC-Link IE TSN)] ⇨ [Network Label Setting]

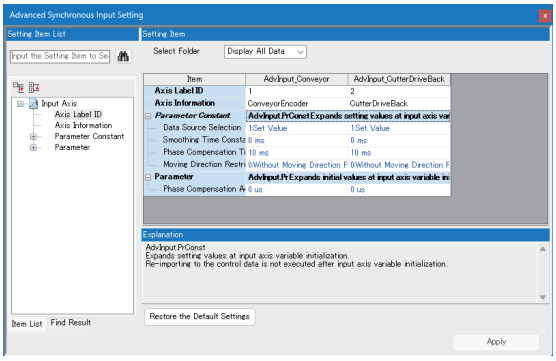
For touch probe function settings, refer to the following.

☞ Page 1164 External Signal High-Accuracy Input

For how to create network labels, refer to the following.

☞ Page 108 Network labels

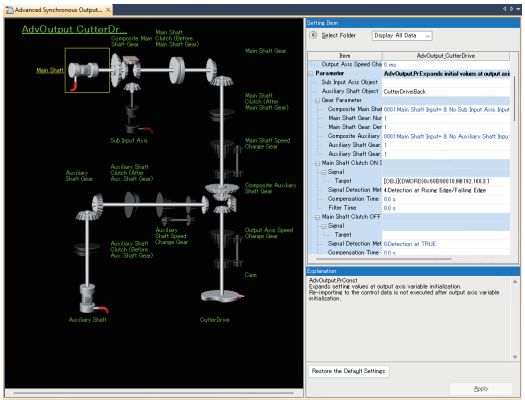
■Advanced synchronous control parameter settings



Set the parameters of the axes to be used as the input/output of the advanced synchronous control FB.

Parameter	Axis used
Input axis parameter	• Conveyor axis • Virtual drive axis for cutter drive axis high-speed return operation
Output axis parameter	• Cutter drive axis

- Input axis parameter settings: In the "Advanced Synchronous Input Setting" window, configure the input axis settings of the main shaft and auxiliary shaft used by the advanced synchronous control FB.



Data name	Setting details
AdvInput_Conveyor	Real encoder axis (ConveyorEncoder) of the conveyor axis
AdvInput_CutterDriveBack	Virtual drive axis (CutterDriveBack) used for cutter drive axis high-speed return operation

Navigation window ⇨ [Motion Setting] ⇨ [Advanced Synchronous Control] ⇨ [Input Setting]

- Output axis parameter settings: In the "Advanced Synchronous Output Setting" window, configure the output axis settings of the output axes used by the advanced synchronous control FB.

Navigation window ⇨ [Motion Setting] ⇨ [Advanced Synchronous Control] ⇨ [Output Setting]

■Settings of axes used by output axis and auxiliary shaft

Setting item	Setting value
Axis information (AdvOutputName.Axis)	CutterDrive (the axis used as the cutter drive axis)
Auxiliary shaft object (AdvOutputName.Pr.AuxAxis)	CutterDriveBack (the axis used for the cutter drive axis high-speed return operation)

■Main shaft clutch setting

Setting item	Setting value
Main shaft clutch ON control setting (AdvOutputName.Pr.Clutch.MasterOnControl)	15: I/O data specification (ClutchSignal)
Main shaft clutch OFF control setting (AdvOutputName.Pr.Clutch.MasterOffControl)	1: Clutch command (ClutchCommand)
Main shaft clutch ON signal setting (Signal target) (AdvOutputName.Pr.MasterOnClutchSignal.Source.Target)	[OBJ]0x60B90010.6@192.168.3.1 (Toggle status for latch completion at the rising edge of touch probe 1)
Main shaft clutch ON signal setting (Signal detection method) (AdvOutputName.Pr.MasterOnClutchSignal.Detection)	4: Detection at rising edge/falling edge (BothEdges)
Main shaft clutch ON signal setting (Compensation time) (AdvOutputName.Pr.MasterOnClutchSignal.CompensationTime)	0.0 [s]
Main shaft clutch ON signal setting (Filter time) (AdvOutputName.Pr.MasterOnClutchSignal.FilterTime)	0.0 [s]
Main shaft clutch reference address setting (AdvOutputName.Pr.Clutch.MasterReference)	0: Current position before gear (GearFrontPosition)
Movement amount before main shaft clutch ON (AdvOutputName.Pr.Clutch.MasterMovementAmountBeforeOn)	0.0 [mm]
Movement amount before main shaft clutch OFF (AdvOutputName.Pr.Clutch.MasterMovementAmountBeforeOff)	330.0 [mm]
Main shaft clutch smoothing method (AdvOutputName.Pr.ClutchMasterSmoothingMethod)	4: Slippage method (linear) (SlippageLinear)
Slippage amount at main shaft clutch ON (AdvOutputName.Pr.Clutch.MasterOnSlippageAmount)	50.0 [mm] (Distance between the sensor position and the cutter drive axis initial position)
Slippage amount at main shaft clutch OFF (AdvOutputName.Pr.Clutch.MasterOffSlippageAmount)	20.0 [mm]

■Gear parameters

Setting item	Setting value
Composite main shaft gear (AdvOutputName.Pr.Gear.MasterCompositeGear)	0001: Main shaft input+ · No input of the sub input axis
Main shaft gear: Numerator (AdvOutputName.Pr.Gear.MasterNumerator)	1
Main shaft gear: Denominator (AdvOutputName.Pr.Gear.MasterDenominator)	1
Composite auxiliary shaft gear (AdvOutputName.Pr.Gear.AuxCompositeGear)	0011: Main shaft input+ · Auxiliary shaft input+
Auxiliary shaft gear: Numerator (AdvOutputName.Pr.Gear.AuxNumerator)	1
Auxiliary shaft gear: Denominator (AdvOutputName.Pr.Gear.AuxDenominator)	1

Program creation

■Enabling the touch probe function of MR-J5(W)-G(-RJ)

Use the label created in "Setting of the sensor input (MR-J5(W)-G(-RJ) touch probe function)" to enable the touch probe function.

• Example program

ST program

```
// TouchProbe Enable
MR_J5_G_RJ_001_TouchProbeFunction:=UINT#16#0013;
```

• Labels used: None

■Starting advanced synchronous control

Check that the input axis is enabled (AdvInput_Conveyor.Md.ActiveStatus is "1: Input axis enabled") and the output axis is on standby (CutterDrive.Md.AxisStatus is "4: Standby (Standstill)") before starting the advanced synchronous control FB.

• Example program

ST program

```
IF gb_SystemStart THEN
    // AdvSync Start
    IF  AdvInput_Conveyor.Md.ActiveStatus=1 AND
        CutterDrive.Md.AxisStatus=MC_AXIS_STATUS__Standstill THEN
        gb_AdvSync_Drive_Enable:=TRUE;
        END_IF;
END_IF;

MCv_AdvancedSync_Drive(
    Master:= AdvInput_Conveyor.Axis,
    Slave:=  AdvOutput_CutterDrive.Axis,
    Enable:= gb_AdvSync_Drive_Enable,
    InSync=> gb_AdvSync_Drive_InSync);
```

• Labels used

Label name	Data type	Comment
gb_SystemStart	Bit	System start command
MCv_AdvancedSync_Drive	MCv_AdvancedSync	Advanced synchronous control FB (cutter drive axis)
gb_AdvSync_Drive_Enable	Bit	Advanced synchronous control FB start command
gb_AdvSync_Drive_InSync	Bit	Advanced synchronous control FB synchronizing

■Starting the conveyor axis (JOG operation)

Check that the output axis is synchronized (AdvOutput_CutterDrive.Md.SyncStatus is "1: In synchronization") and start JOG operation on the conveyor axis.

• Example program

ST program

```
IF gb_SystemStart THEN
    // ConveyorAxis Move
    IF AdvOutput_CutterDrive.Md.SyncStatus=1 THEN
        gl_SetSpeedComveyor:=40000000.0;
        gb_MoveConveyorReq:=TRUE;
        END_IF;
    END_IF;

MCv_Jog_Conveyor(
    Axis:= Conveyor.AxisRef,
    JogForward:= gb_MoveConveyorReq,
    Velocity:= gl_SetSpeedComveyor,
    Acceleration:= 0.5,
    Deceleration:= 0.5,
    Options:= H0001);
```

• Labels used

Label name	Data type	Comment
gb_SystemStart	Bit	System start command
MCv_Jog_Conveyor	MCv_Jog	JOG operation FB (conveyor axis)
gb_MoveConveyorReq	Bit	Positive direction JOG operation command
gl_SetSpeedComveyor	Double-precision real number	Command velocity of JOG operation

■Positioning control of the vertical cutter axis

Check that smoothing is complete with output axis main shaft clutch ON (Main shaft clutch ON/OFF status (AdvOutput_CutterDrive.Md.Clutch.MasterOnOffStatus) is TRUE and Main shaft clutch smoothing status (AdvOutput_CutterDrive.Md.Clutch.MasterSmoothingStatus) is FALSE) before starting positioning control of the vertical cutter axis. (An example of a two-way operation conducted by multiple start with Buffered.)

• Example program

ST program

```
IF AdvOutput_CutterDrive.Md.Clutch.MasterOnOffStatus AND
   NOT(AdvOutput_CutterDrive.Md.Clutch.MasterSmoothingStatus) AND
   NOT(lb_CutterMoveComp) THEN

   MC_MoveAbsolute_1.Execute:=TRUE;
   IF MC_MoveAbsolute_1.Busy THEN
      MC_MoveAbsolute_2.Execute:=TRUE;
   END_IF;
END_IF;

IF MC_MoveAbsolute_1.Done AND
   MC_MoveAbsolute_2.Done THEN
   MC_MoveAbsolute_1.Execute:=FALSE;
   MC_MoveAbsolute_2.Execute:=FALSE;
   lb_CutterMoveComp:=TRUE;
END_IF;

MC_MoveAbsolute_1(
   Axis:= CutterUpDown.AxisRef,
   Position:= 30000.0 ,//30.0[mm]
   Velocity:= 3000000.0 ,//3000000.0[mm/min]
   Acceleration:= 0.1,
   Deceleration:= 0.1,
   Direction:= MC_DIRECTION__mcShortestWay,
   Options:= H0001);

MC_MoveAbsolute_2(
   Axis:= CutterUpDown.AxisRef,
   Position:= 0.0,
   Velocity:= 3000000.0 ,
   Acceleration:= 0.1,
   Deceleration:= 0.1,
   Direction:= MC_DIRECTION__mcShortestWay ,
   BufferMode:= MC_BUFFER_MODE__mcBuffered,
   Options:= H0001);
```

• Labels used

Label name	Data type	Comment
MC_MoveAbsolute_1	MC_MoveAbsolute	Absolute positioning (cutting operation)
MC_MoveAbsolute_2	MC_MoveAbsolute	Absolute positioning (retracting operation)
lb_CutterMoveComp	Bit	Cutter operation complete flag

■Cutter drive axis high-speed return operation (positioning control of the virtual drive axis set to auxiliary shaft)

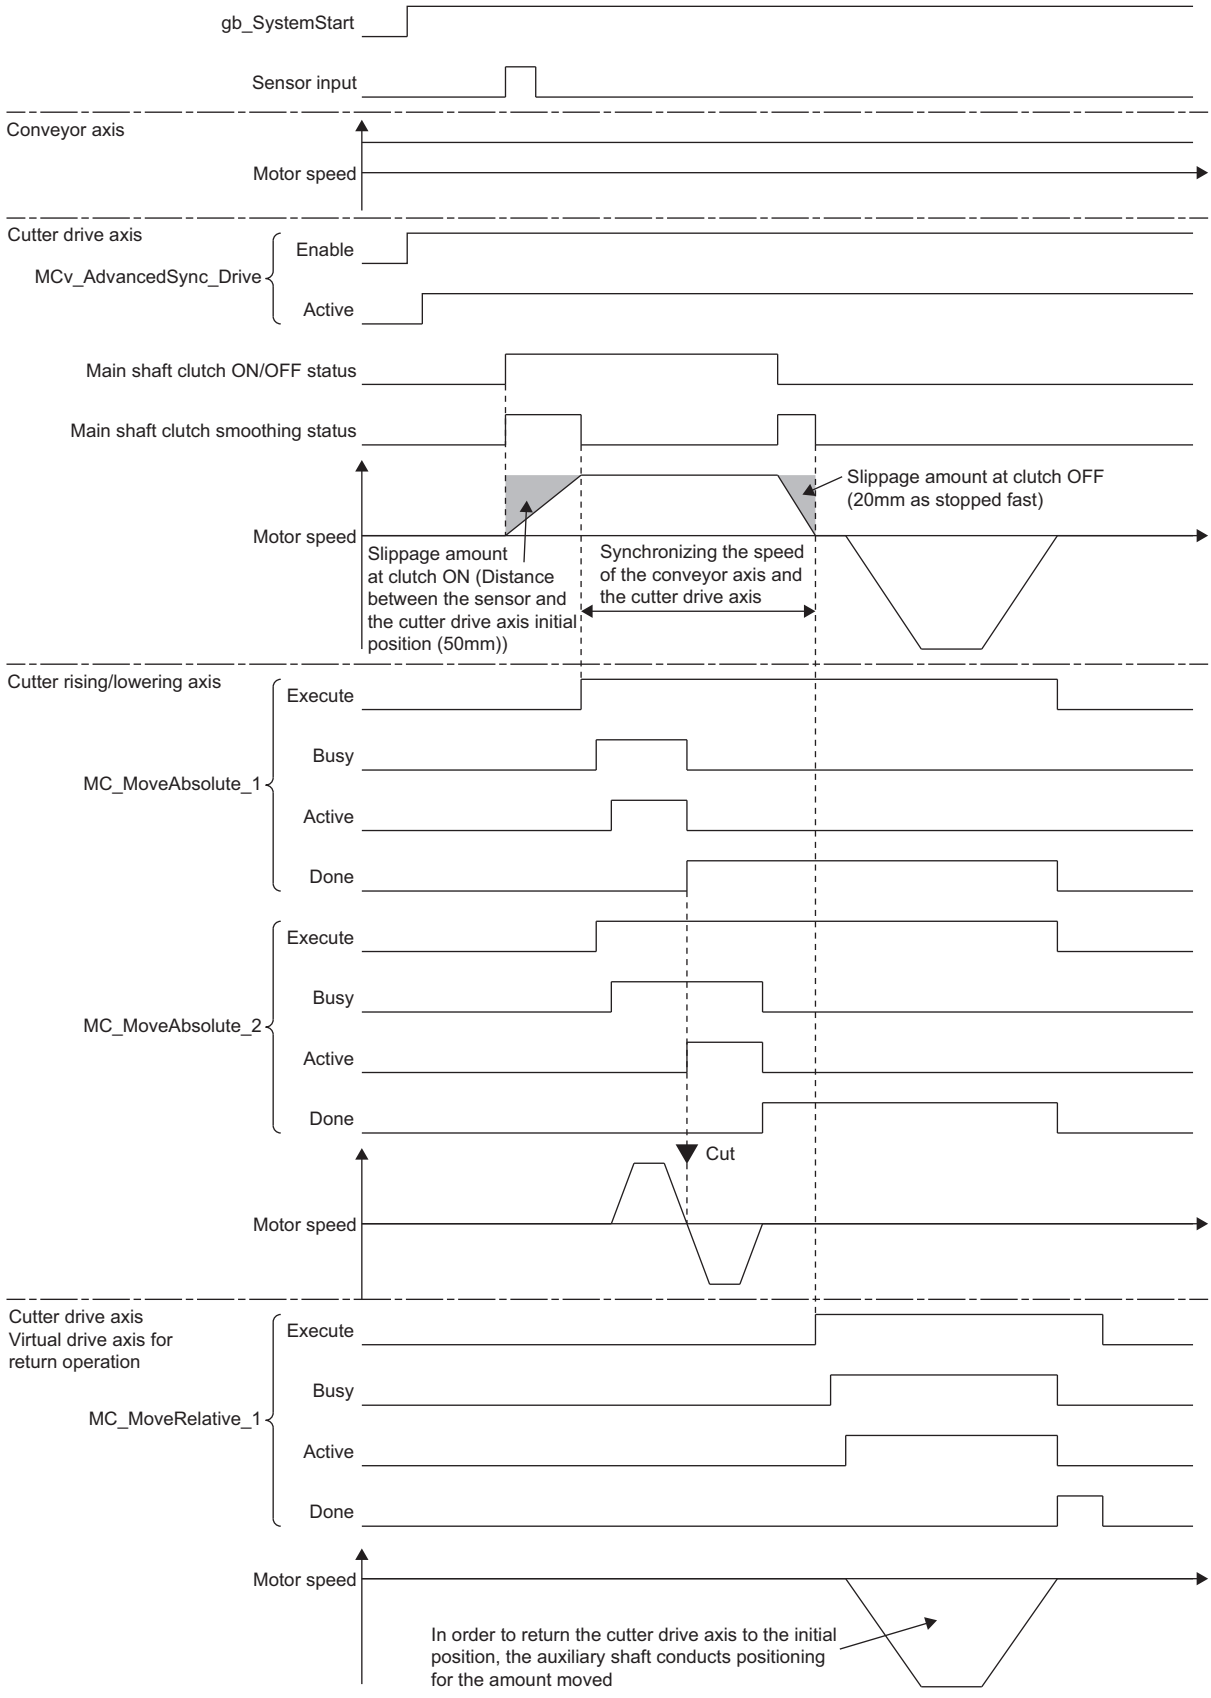
Check that smoothing is complete with output axis main shaft clutch OFF (Main shaft clutch ON/OFF status (AdvOutput_CutterDrive.Md.Clutch.MasterOnOffStatus) is FALSE and Main shaft clutch smoothing status (AdvOutput_CutterDrive.Md.Clutch.MasterSmoothingStatus) is FALSE), and positioning control of the vertical cutter axis is complete before starting positioning control of the virtual drive axis (CutterDriveBack) set to the auxiliary shaft.

• Example program

ST program

```
IF NOT(AdvOutput_CutterDrive.Md.Clutch.MasterOnOffStatus) AND
   NOT(AdvOutput_CutterDrive.Md.Clutch.MasterSmoothingStatus) AND
   lb_CutterMoveComp THEN
   MC_MoveRelative_1.Execute:=TRUE;
END_IF;

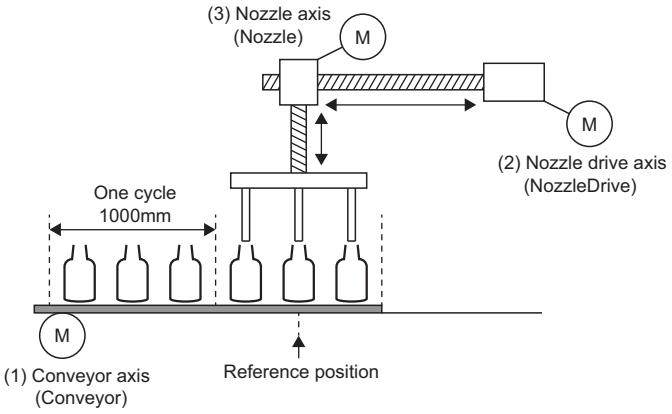
IF MC_MoveRelative_1.Done THEN
   MC_MoveRelative_1.Execute:=FALSE;
   lb_CutterMoveComp:=FALSE;
END_IF;



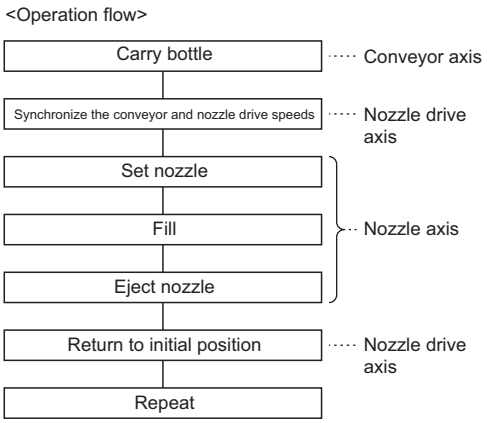
MC_MoveRelative_1(
   Axis:= CutterDriveBack.AxisRef,
   Distance:= -250000.0,
   Velocity:= 3000000.0,
   Acceleration:= 0.5,
   Deceleration:= 0.5,
   Options:= H0001);
```

• Labels used

Label name	Data type	Comment
MC_MoveRelative_1	MC_MoveRelative	Relative positioning (cutter drive axis return operation)
lb_CutterMoveComp	Bit	Cutter operation complete flag



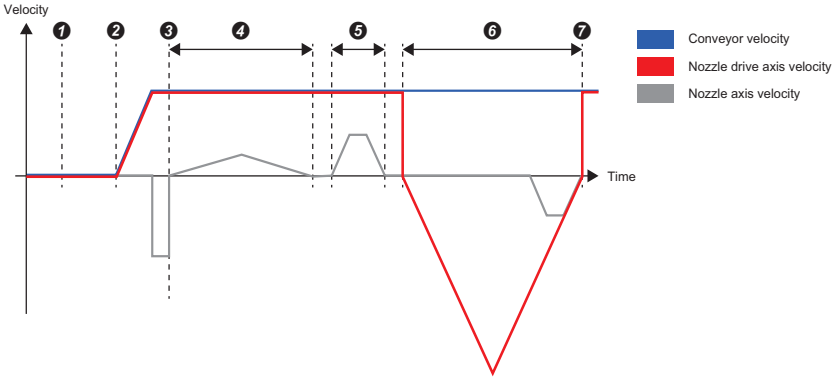
Timing chart

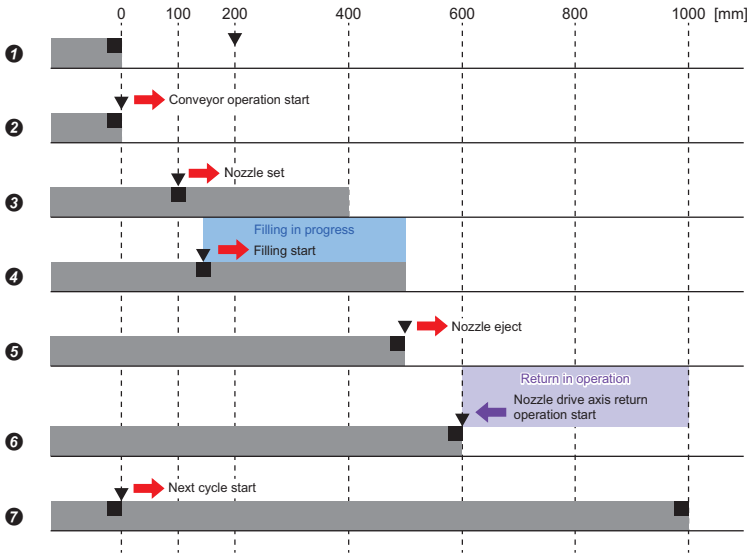


The timing chart for the operation that uses the program example is shown below.

Filling machine

This section describes the example program and how to use synchronous control of multiple axes that use advanced synchronous control FB operation profile data (cam data), and how to restart synchronous control based on a filling machine system.

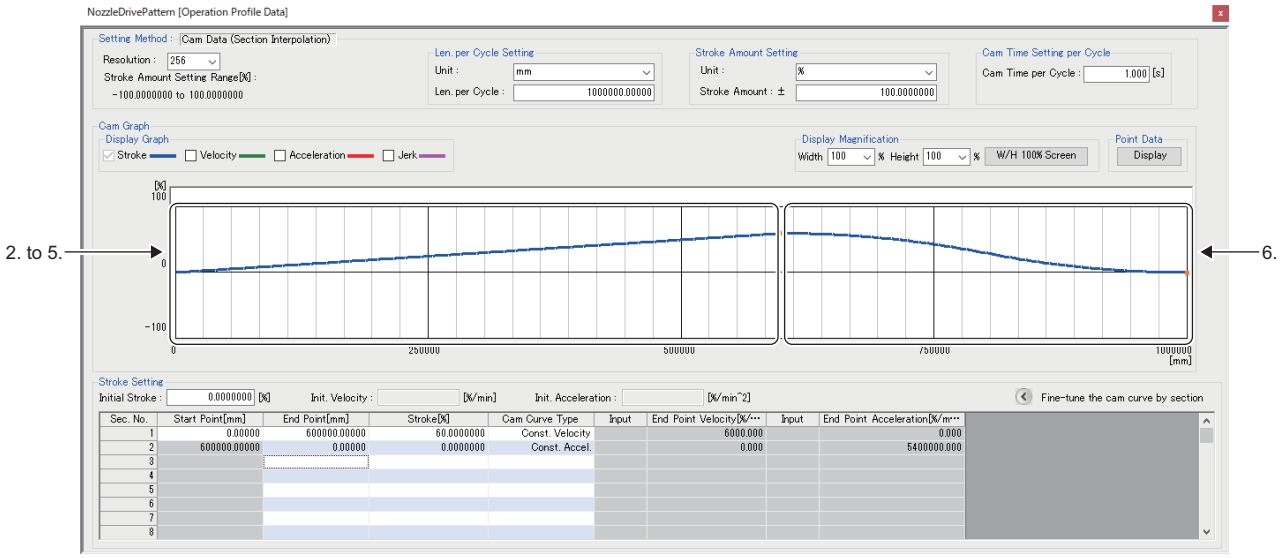




Setting item	(1) Conveyor axis	(2) Nozzle drive axis	(3) Nozzle axis
Axis name	Conveyor	NozzleDrive	Nozzle
Axis type	Real drive axis	Real drive axis	Real drive axis
Station address	192.168.3.1	192.168.3.2	192.168.3.3
Position command unit	μm	μm	μm
Velocity command unit	U/min	U/min	U/min

Operation overview

1. An advanced synchronous control FB starts with the conveyor axis as the input axis and the nozzle drive axis as the output axis. Additionally, an advanced synchronous control FB starts with the conveyor axis as the input axis and the nozzle axis as the output axis.
2. The conveyor axis starts. The nozzle drive axis and the nozzle axis synchronize with the conveyor axis according to the set length per cycle and operation profile data (cam data) and execute the operations in steps 3 to 6.
3. The nozzle is set on the nozzle axis.
4. The bottle is filled.
5. The nozzle on the nozzle axis is ejected.
6. The nozzle drive axis and nozzle axis return to the reference position.
7. Steps 3 to 6 are repeated.

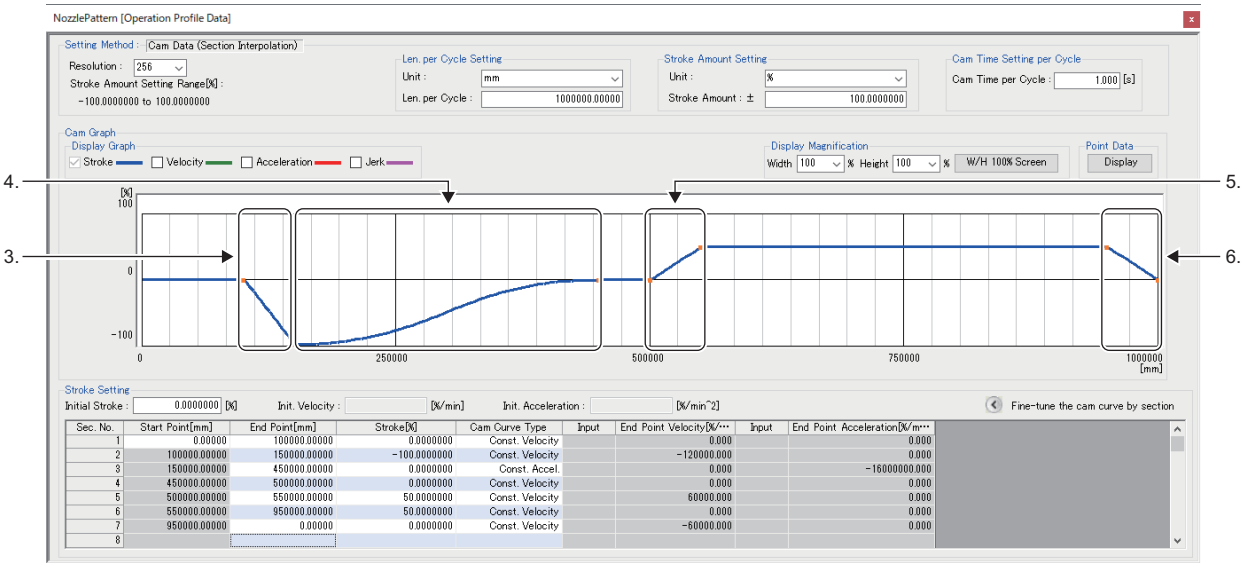


Creating operation profile data (cam data)

The following describes how to create the operation profile data (cam data) used by the nozzle drive axis and nozzle axis (output axes).

■Creating the nozzle drive axis operation profile data (cam data)

Create the "NozzleDrivePattern" cam data below with "Profile ID: 1" as the operation profile data (cam data).



Step	Cam pattern details of each step	Setting details
2. to 5.	Cam pattern that synchronizes the speed with the conveyor axis	• Current position per cycle: 0.0 [mm] → 600000.0 [mm] • Stroke amount: 0.0 [%] → 60.0 [%]
6.	Cam pattern that returns the nozzle drive axis to the reference position	• Current position per cycle: 600000.0 [mm] → 1000000.0 [mm] (0.0 [mm]) • Stroke amount: 60.0 [%] → 0.0 [%]

■Creating the nozzle axis operation profile data (cam data)

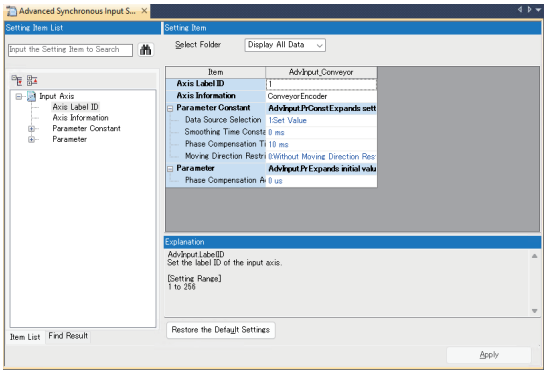
Create the "NozzlePattern" cam data below with "Profile ID: 2" as the operation profile data (cam data).

Step	Cam pattern details of each step	Setting details
3.	Cam pattern for the nozzle setting operation	• Current position per cycle: 100000.0 [mm] → 150000.0 [mm] • Stroke amount: 0.0 [%] → -100.0 [%]
4.	Cam pattern while filling (operation that gradually raises the nozzle)	• Current position per cycle: 150000.0 [mm] → 450000.0 [mm] • Stroke amount: -100.0 [%] → 0.0 [%]
5.	Cam pattern for the nozzle eject operation	• Current position per cycle: 500000.0 [mm] → 550000.0 [mm] • Stroke amount: 0.0 [%] → 50.0 [%]
6.	Cam pattern that returns the nozzle to the reference position	• Current position per cycle: 950000.0 [mm] → 1000000 [mm] (0.0 [mm]) • Stroke amount: 50.0 [%] → 0.0 [%]

Parameter settings

Set the input axis parameters for the axis (conveyor axis) to be used as the input for the advanced synchronous control FB and the output axis parameters for the axes (nozzle drive axis and nozzle axis) to be used as the output for the advanced synchronous control FB.

Set the parameters for the axes used as the input/output for the advanced synchronous control FB.

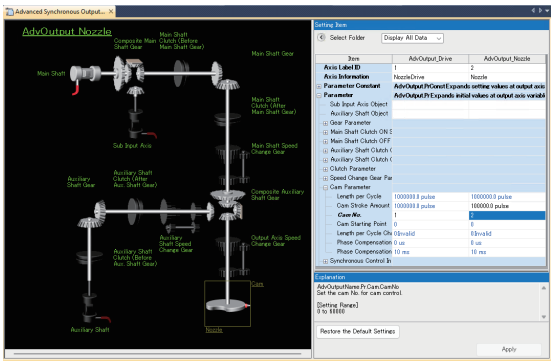


Parameter	Axis used
Input axis parameter	Conveyor axis
Output axis parameter	• Nozzle drive axis • Nozzle axis

■Advanced synchronous control input axis parameter settings

In the "Advanced Synchronous Input Setting" window, configure the input axis settings of the main shaft and auxiliary shaft used by the advanced synchronous control FB.

Data name	Setting details
AdvInput_Conveyor	Real drive axis (Conveyor) of the conveyor axis



Navigation window ⇨ [Motion Setting] ⇨ [Advanced Synchronous Control] ⇨ [Input Setting]

■Advanced synchronous control FB output axis parameter settings

In the "Advanced Synchronous Output Setting" window, configure the output axis settings of the output axes used by the advanced synchronous control FB.

Navigation window ⇨ [Motion Setting] ⇨ [Advanced Synchronous Control] ⇨ [Output Setting]

- Settings of axes used by output axis and auxiliary shaft

Setting item	Setting value	
	Nozzle drive axis	Nozzle axis
Axis information (AdvOutputName.Axis)	NozzleDrive	Nozzle

- Cam parameter setting

Setting item	Setting value	
	Nozzle drive axis	Nozzle axis
Length per cycle	1000000.0 (Match with the length per cycle set in the operation profile data)	1000000.0 (Match with the length per cycle set in the operation profile data)
Cam stroke amount	1000000.0 (Same as the length per cycle)	100000.0 (Set the stroke amount of the output axis when the stroke amount [%] set in the operation profile data is 100 [%].)
Cam No.	1 (The profile ID set in the operation profile data (NozzleDrivePattern))	2 (The profile ID set in the operation profile data (NozzlePattern))

Program creation

■Starting advanced synchronous control (initial start)

After setting the positions of the input axis and output axes by homing or other methods, check that the input axis is enabled (AdvInput_Conveyor.Md.ActiveStatus is "1: Input axis enabled") and the output axes are on standby (NozzleDrive.Md.AxisStatus is "4: Standby (Standstill)" and Nozzle.Md.AxisStatus is "4: Standby (Standstill)") before starting the advanced synchronous control FB. This section also describes the procedures for restarting synchronous control using cam set position restoration (restoring the input axis position as reference).

For restarting synchronous control using cam set position restoration (restoring the input axis position as reference), refer to the following.

☞ Page 1039 Starting advanced synchronous control (restart)

Set the positions of the input axis (Conveyor) and the output axes (NozzleDrive and Nozzle), set the synchronous control initial position parameters as shown below, and start the advanced synchronous control FB.

Setting item	Setting value
Setting method of current position per cycle after main shaft gear • AdvOutput_NozzleDrive.Pr.Restore.MasterGearPositionPerCycleMethod • AdvOutput_Nozzle.Pr.Restore.MasterGearPositionPerCycleMethod	2: Calculate from input axis (CalculateFromInputAxis)
Cam axis position restoration object • AdvOutput_NozzleDrive.Pr.Restore.PositionRestorationObject • AdvOutput_Nozzle.Pr.Restore.PositionRestorationObject	0: Current position per cycle restoration (RestorePositionPerCycle)
Setting method of cam reference position • AdvOutput_NozzleDrive.Pr.Restore.ReferenceSetPositionMethod • AdvOutput_Nozzle.Pr.Restore.ReferenceSetPositionMethod	2: Cam set position (CamSetPosition)
Current position per cycle (initial setting) • AdvOutput_NozzleDrive.Pr.Restore.InitialPositionPerCycle • AdvOutput_Nozzle.Pr.Restore.InitialPositionPerCycle	0.0

• Example program

■Nozzle drive axis

ST program

```
IF NOT(gb_SystemStart) THEN
   gb_PositionAdjustComp_Drive:=FALSE;
   END_IF;

//----------For initial start (from here)----------
IF gb_SystemStart AND NOT(gb_SyncRestart) THEN
   // AdvSync Start(NozzleDrive)
   // Set Restore Parameter

■Starting advanced synchronous control (restart)

When restarting advanced synchronous control, select a restoration method suitable for the configuration and application of the equipment and start the advanced synchronous control FB. Additionally, use "synchronous control analysis mode" or "cam position calculation function" when recalculating to synchronize the input axis and output axis in order to restart advanced synchronous control.

An example of restoration procedures when using "synchronous control analysis mode" or "cam position calculation function" is shown below.

No.	Restoration method	Using method	Application
1	Current position per cycle restoration	Synchronous control analysis mode	Restart synchronization after moving the nozzle axis to the retract point.
2		Cam position calculation function (MCv_AdvCamSetPositionCalc (Advanced synchronous control current position per cycle calculation))	
3	Cam set position restoration	Synchronous control analysis mode	Restart with the phases of input axis cumulative current position and the output axis current position per cycle matched. (When the workpiece has not been set)
4		Cam position calculation function (MCv_AdvPositionPerCycleCalc (Advanced synchronous control cam set position calculation))	

Point

For restoration after turning on the motion system power again, the input axis and output axis must be set to an absolute position detection system.

Operating procedure

■No.1 "Restart synchronization after moving the nozzle axis to the retract point" (when using synchronous control analysis mode)

1. Position the output axis (Nozzle) to the retract point (position of stroke amount "50%").
2. Set the synchronous control initial position parameters of the output axis (Nozzle) as follows, and execute the advanced synchronous control FB with the synchronous control analysis mode setting (Options (Options): Bit 16) set to "1: Enabled".

Setting item	Setting value
Setting method of current position per cycle after main shaft gear • AdvOutput_Nozzle.Pr.Restore.MasterGearPositionPerCycleMethod	2: Calculate from input axis (CalculateFromInputAxis)
Cam axis position restoration object • AdvOutput_Nozzle.Pr.Restore.PositionRestorationObject	0: Current position per cycle restoration (RestorePositionPerCycle)
Setting method of cam reference position • AdvOutput_Nozzle.Pr.Restore.ReferenceSetPositionMethod	0: Previous value (PreviousPosition)
Current position per cycle (initial setting) • AdvOutput_NozzleDrive.Pr.Restore.InitialPositionPerCycle	0.0

3. To calculate the Cam set position (AdvOutput_Drive.Md.Cam.SetPosition) at the start of advanced synchronous control of the output axis (NozzleDrive) based on the current position per cycle calculated in step 2, set the synchronous control initial position parameters of the output axis (NozzleDrive) as follows, and execute the advanced synchronous control FB with the synchronous control analysis mode setting (Options (Options): Bit 16) set to "1: Enabled".

Setting item	Setting value
Setting method of current position per cycle after main shaft gear • AdvOutput_NozzleDrive.Pr.Restore.MasterGearPositionPerCycleMethod	2: Calculate from input axis (CalculateFromInputAxis)
Cam axis position restoration object • AdvOutput_NozzleDrive.Pr.Restore.PositionRestorationObject	2: Cam set position restoration (RestoreCamSetPosition)
Setting method of cam reference position • AdvOutput_NozzleDrive.Pr.Restore.ReferenceSetPositionMethod	0: Previous value (PreviousPosition)
Setting method of current position per cycle • AdvOutput_NozzleDrive.Pr.Restore.PositionPerCycleMethod	1: Current position per cycle (initial setting) (InitialPositionPerCycle)
Current position per cycle (initial setting) • AdvOutput_NozzleDrive.Pr.Restore.InitialPositionPerCycle	Current position per cycle calculated in step 2 • AdvOutput_Nozzle.Md.Cam.PositionPerCycle

4. After synchronous control analysis mode execution completion (MCv_AdvancedSync.Done is TRUE), position the nozzle drive axis (NozzleDrive) to the position of the updated Cam set position (AdvOutput_Drive.Md.Cam.SetPosition).
5. Set the synchronous control initial position parameters of the output axes (NozzleDrive and Nozzle) as follows, and start (change Execute from FALSE to TRUE) the advanced synchronous control FB.

Setting item	Setting value
Setting method of current position per cycle after main shaft gear • AdvOutput_NozzleDrive.Pr.Restore.MasterGearPositionPerCycleMethod • AdvOutput_Nozzle.Pr.Restore.MasterGearPositionPerCycleMethod	2: Calculate from input axis (CalculateFromInputAxis)
Cam axis position restoration object • AdvOutput_NozzleDrive.Pr.Restore.PositionRestorationObject • AdvOutput_Nozzle.Pr.Restore.PositionRestorationObject	0: Current position per cycle restoration (RestorePositionPerCycle)
Setting method of cam reference position • AdvOutput_NozzleDrive.Pr.Restore.ReferenceSetPositionMethod • AdvOutput_Nozzle.Pr.Restore.ReferenceSetPositionMethod	0: Previous value (PreviousPosition)
Current position per cycle (initial setting) • AdvOutput_NozzleDrive.Pr.Restore.InitialPositionPerCycle • AdvOutput_Nozzle.Pr.Restore.InitialPositionPerCycle	Current position per cycle calculated in step 2 • AdvOutput_Nozzle.Md.Cam.PositionPerCycle

☞ Page 1035 Starting advanced synchronous control (initial start)

■No.2 "Restart synchronization after moving the nozzle axis to the retract point" (when using cam position calculation function (MCv_AdvCamSetPositionCalc (Advanced Synchronous Control Current Position Per Cycle Calculation)))

1. Position the output axis (Nozzle) to the retract point (position of stroke amount "50%").
2. Calculate the current position per cycle based on the set position of the output axis (output axis (Nozzle) in this case) which keeps the set position.

Setting item	Setting value
Cam table ID • MCv_AdvPositionPerCycleCalc_Nozzle.CamTableID	Cam No. of output axis (Nozzle) • AdvOutput_Nozzle.Pr.Cam.CamNo
Cam position length per cycle • MCv_AdvPositionPerCycleCalc_Nozzle.LengthPerCycle	Length per cycle of output axis (Nozzle) • AdvOutput_Nozzle.Pr.Cam.LengthPerCycle
Cam position calculation stroke amount • MCv_AdvPositionPerCycleCalc_Nozzle.StrokeAmount	Stroke amount of output axis (Nozzle) • AdvOutput_Nozzle.Pr.Cam.StrokeAmount
Cam position calculation cam set position • MCv_AdvPositionPerCycleCalc_Nozzle.CamSetPosition	Set position of output axis (Nozzle) • AdvOutput_Nozzle.Md.SetPosition
Cam position calculation cam reference position • MCv_AdvPositionPerCycleCalc_Nozzle.ReferenceSetPosition	Cam reference position of output axis (Nozzle) • AdvOutput_Nozzle.Md.Cam.ReferenceSetPosition
Cam position calculation current position per cycle • MCv_AdvPositionPerCycleCalc_Nozzle.PositionPerCycle	Current position per cycle of output axis (Nozzle) • AdvOutput_Nozzle.Md.Cam.PositionPerCycle

3. Calculate the cam set position of the output axis (NozzleDrive) based on the current position per cycle calculated in step 2.

Setting item	Setting value
Cam table ID • MCv_AdvCamSetPositionCalc_Drive.CamTableID	Cam No. of output axis (NozzleDrive) • AdvOutput_Drive.Pr.Cam.CamNo
Cam position length per cycle • MCv_AdvCamSetPositionCalc_Drive.LengthPerCycle	Length per cycle of output axis (NozzleDrive) • AdvOutput_Drive.Pr.Cam.LengthPerCycle
Cam position calculation stroke amount • MCv_AdvCamSetPositionCalc_Drive.StrokeAmount	Stroke amount of output axis (NozzleDrive) • AdvOutput_Drive.Pr.Cam.StrokeAmount
Cam position calculation cam reference position • MCv_AdvCamSetPositionCalc_Drive.ReferenceSetPosition	Cam reference position of output axis (NozzleDrive) • AdvOutput_Drive.Md.Cam.ReferenceSetPosition
Cam position calculation current position per cycle • MCv_AdvCamSetPositionCalc_Drive.PositionPerCycle	Current position per cycle calculated in step 2 • MCv_AdvPositionPerCycleCalc.CalculationResult

4. Position the output axis (NozzleDrive) to the cam set position calculated in step 3, and match the current position per cycle of the output axis (Nozzle) and output axis (NozzleDrive).
5. Set the synchronous control initial position parameters of the output axes (NozzleDrive and Nozzle) as shown below, and start (change Enable from FALSE to TRUE) the advanced synchronous control FB.

Setting item	Setting value
Setting method of current position per cycle after main shaft gear • AdvOutput_NozzleDrive.Pr.Restore.MasterGearPositionPerCycleMethod • AdvOutput_Nozzle.Pr.Restore.MasterGearPositionPerCycleMethod	2: Calculate from input axis (CalculateFromInputAxis)
Cam axis position restoration object • AdvOutput_NozzleDrive.Pr.Restore.PositionRestorationObject • AdvOutput_Nozzle.Pr.Restore.PositionRestorationObject	0: Current position per cycle restoration (RestorePositionPerCycle)
Setting method of cam reference position • AdvOutput_NozzleDrive.Pr.Restore.ReferenceSetPositionMethod • AdvOutput_Nozzle.Pr.Restore.ReferenceSetPositionMethod	0: Previous value (PreviousPosition)
Setting method of current position per cycle • AdvOutput_NozzleDrive.Pr.Restore.PositionPerCycleMethod • AdvOutput_Nozzle.Pr.Restore.PositionPerCycleMethod	1: Current position per cycle (initial setting) (InitialPositionPerCycle)

☞ Page 1035 Starting advanced synchronous control (initial start)

■No.3 "Restart with the phases of input axis cumulative current position and the output axis current position per cycle matched" (when using synchronous control analysis mode)

1. Set the synchronous control initial position parameters of the output axes (NozzleDrive and Nozzle) as follows, and execute the advanced synchronous control FB with the synchronous control analysis mode setting (Options (Options): Bit 16) set to "1: Enabled".
2. After synchronous control analysis mode execution completion (MCv_AdvancedSync.Done is TRUE), use the updated Cam set position (AdvOutput_Drive.Md.Cam.SetPosition, AdvOutput_Nozzle.Md.Cam.SetPosition) to position the nozzle drive axis (NozzleDrive) and nozzle axis (Nozzle) to the position of the updated cam set position.
3. Set the synchronous control analysis mode setting (Options (Options): Bit 16) to "0: Disabled" and start (change Enable from FALSE to TRUE) the advanced synchronous control FB again.

Setting item	Setting value
Setting method of current position per cycle after main shaft gear • AdvOutput_NozzleDrive.Pr.Restore.MasterGearPositionPerCycleMethod • AdvOutput_Nozzle.Pr.Restore.MasterGearPositionPerCycleMethod	2: Calculate from input axis (CalculateFromInputAxis)
Cam axis position restoration object • AdvOutput_NozzleDrive.Pr.Restore.PositionRestorationObject • AdvOutput_Nozzle.Pr.Restore.PositionRestorationObject	2: Cam set position restoration (RestoreCamSetPosition)
Setting method of cam reference position • AdvOutput_NozzleDrive.Pr.Restore.ReferenceSetPositionMethod • AdvOutput_Nozzle.Pr.Restore.ReferenceSetPositionMethod	0: Previous value (PreviousPosition)
Setting method of current position per cycle • AdvOutput_NozzleDrive.Pr.Restore.PositionPerCycleMethod • AdvOutput_Nozzle.Pr.Restore.PositionPerCycleMethod	2: Current position per cycle after main shaft gear (MasterGearPositionPerCycle)

■No.4 "Restart with the phases of input axis cumulative current position and the output axis current position per cycle matched" (when using the cam position calculation function (MCv_AdvPositionPerCyclecalc (Advanced Synchronous Control Cam Set Position Calculation)))

1. Use the cumulative current position of the input axis (Conveyor) to calculate the cam set position with the following settings, and calculate the cam set position of the output axes (NozzleDrive and Nozzle).

Setting item	Setting value	
	Output axis (NozzleDrive)	Output axis (Nozzle)
Cam table ID • MCv_AdvCamSetPositionCalc_Drive.CamTableID • MCv_AdvCamSetPositionCalc_Nozzle.CamTableID	Cam No. of output axis (NozzleDrive) • AdvOutput_Drive.Pr.Cam.CamNo	Cam No. of output axis (Nozzle) • AdvOutput_Nozzle.Pr.Cam.CamNo
Cam position length per cycle • MCv_AdvCamSetPositionCalc_Drive.LengthPerCycle • MCv_AdvCamSetPositionCalc_Nozzle.LengthPerCycle	Length per cycle of output axis (NozzleDrive) • AdvOutput_Drive.Pr.Cam.LengthPerCycle	Length per cycle of output axis (Nozzle) • AdvOutput_Nozzle.Pr.Cam.LengthPerCycle
Cam position calculation stroke amount • MCv_AdvCamSetPositionCalc_Drive.StrokeAmount • MCv_AdvCamSetPositionCalc_Nozzle.StrokeAmount	Stroke amount of output axis (NozzleDrive) • AdvOutput_Drive.Pr.Cam.StrokeAmount	Stroke amount of output axis (Nozzle) • AdvOutput_Nozzle.Pr.Cam.StrokeAmount
Cam position calculation cam reference position • MCv_AdvCamSetPositionCalc_Drive.ReferenceSetPosition • MCv_AdvCamSetPositionCalc_Nozzle.ReferenceSetPosition	Cam reference position of output axis (NozzleDrive) • AdvOutput_Drive.Md.Cam.ReferenceSetPosition	Cam reference position of output axis (Nozzle) • AdvOutput_Nozzle.Md.Cam.ReferenceSetPosition
Cam position calculation current position per cycle • MCv_AdvCamSetPositionCalc_Drive.PositionPerCycle • MCv_AdvCamSetPositionCalc_Nozzle.PositionPerCycle	The value of the input axis (Conveyor) cumulative current position rounded within the cam position length per cycle*1	The value of the input axis (Conveyor) cumulative current position rounded within the cam position length per cycle*1

*1 When main shaft/auxiliary shaft gear or main shaft/auxiliary shaft speed change gear are set, the gear ratio and speed change ratio for the movement amount from synchronization stop until restart need to be taken into account of in the calculation. When setting gears and speed change gears, using synchronous control analysis mode is recommended.

2. Position to the position of the cam set position (MCv_AdvCamSetPositionCalc.CalculationResult) calculated with the nozzle drive axis (NozzleDrive) and nozzle axis (Nozzle) in step 1.

3. Set the synchronous control initial position parameters of the output axes (NozzleDrive and Nozzle) as shown below, and start (change Enable from FALSE to TRUE) the advanced synchronous control FB.

Setting item	Setting value
Setting method of current position per cycle after main shaft gear • AdvOutput_NozzleDrive.Pr.Restore.MasterGearPositionPerCycleMethod • AdvOutput_Nozzle.Pr.Restore.MasterGearPositionPerCycleMethod	2: Calculate from input axis (CalculateFromInputAxis)
Cam axis position restoration object • AdvOutput_NozzleDrive.Pr.Restore.PositionRestorationObject • AdvOutput_Nozzle.Pr.Restore.PositionRestorationObject	2: Cam set position restoration (RestoreCamSetPosition)
Setting method of cam reference position • AdvOutput_NozzleDrive.Pr.Restore.ReferenceSetPositionMethod • AdvOutput_Nozzle.Pr.Restore.ReferenceSetPositionMethod	0: Previous value (PreviousPosition)
Setting method of current position per cycle • AdvOutput_NozzleDrive.Pr.Restore.PositionPerCycleMethod • AdvOutput_Nozzle.Pr.Restore.PositionPerCycleMethod	2: Current position per cycle after main shaft gear (MasterGearPositionPerCycle)

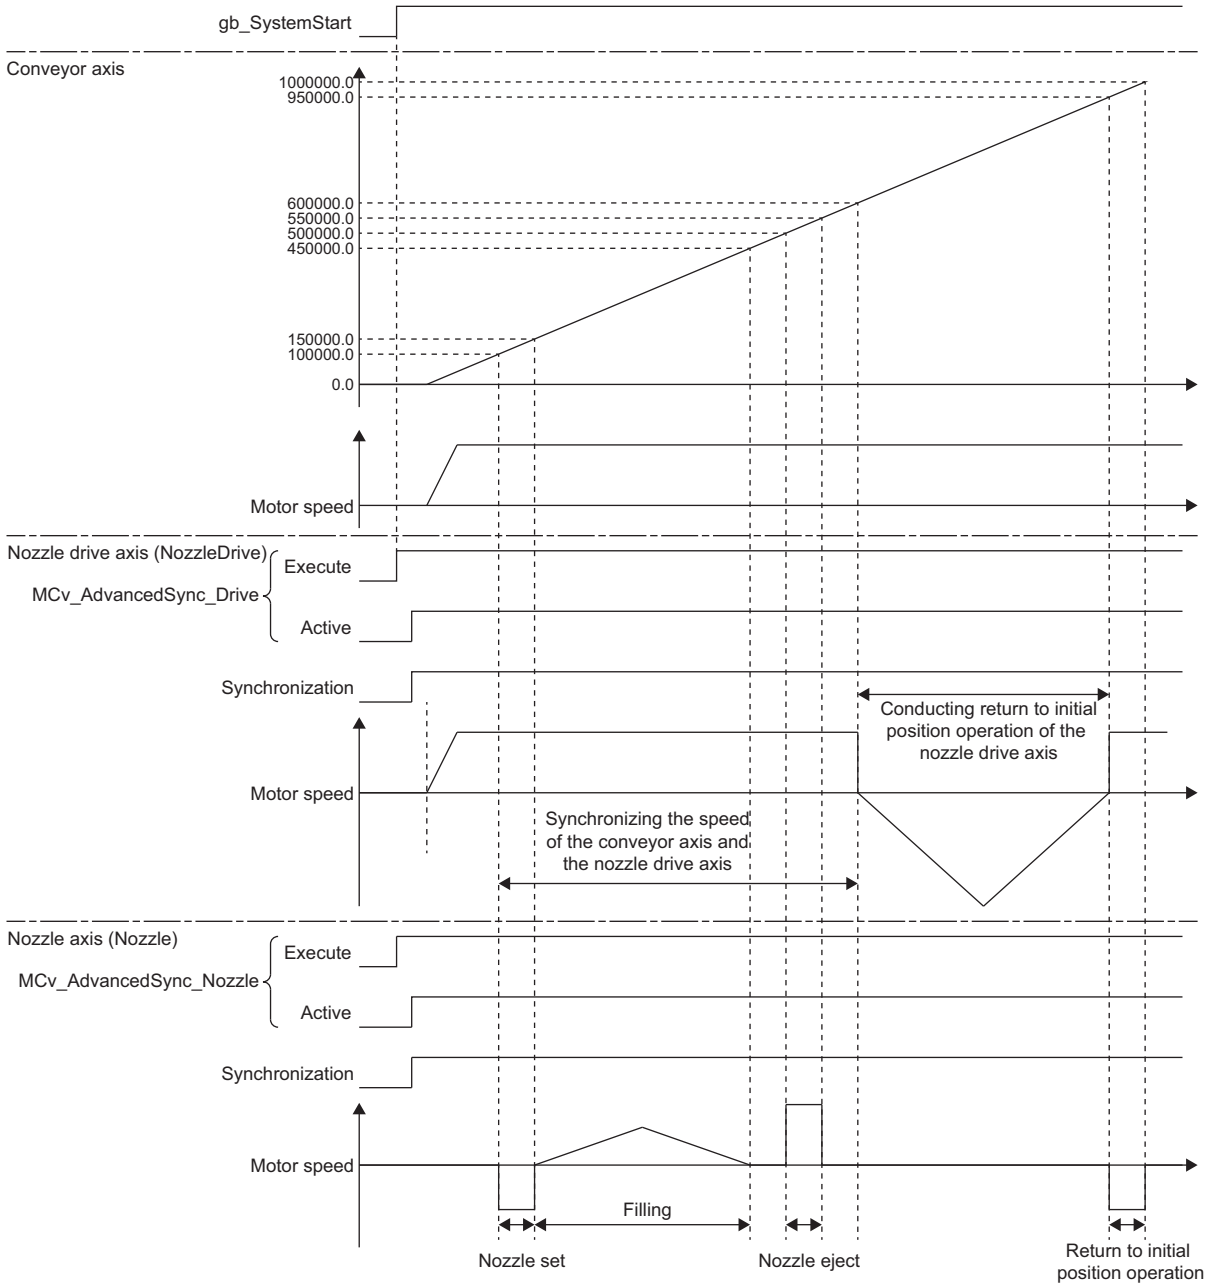
■Starting the conveyor axis (JOG operation)

Check that the output axes are synchronized (AdvOutput_Drive.Md.SyncStatus is "1: In synchronization" and AdvOutput_Nozzle.Md.SyncStatus is "1: In synchronization") and start the conveyor axis (Conveyor).

• Example program

ST program

```
IF gb_SystemStart THEN
    // Conveyor Move
    IF AdvOutput_Drive.Md.SyncStatus=1 AND AdvOutput_Nozzle.Md.SyncStatus=1 THEN
        gl_SetSpeedComveyor:=10000000.0;
        gb_MoveConveyorReq:=TRUE;
    END_IF;
END_IF;



MCv_Jog_Conveyor(
    Axis:= Conveyor.AxisRef,
    JogForward:= gb_MoveConveyorReq,
    Velocity:= gl_SetSpeedComveyor,
    Acceleration:= 0.5,
    Deceleration:= 0.5,
    Options:= H0001);
```

• Labels used

Label name	Data type	Comment
gb_SystemStart	Bit	System start command
MCv_Jog_Conveyor	MCv_Jog	JOG operation FB (conveyor axis)
gb_MoveConveyorReq	Bit	Positive direction JOG operation command
gl_SetSpeedComveyor	Double-precision real number	Command velocity of JOG operation

Timing chart

The timing chart for the operation that uses the program example is shown below.

34 FUNCTIONS RELATED TO POSITION

The functions related to position have the following items.

Item	Description	Reference
Current position change function	Changes the set position and cumulative current position to any address.	Page 1054 Current Position Change Function
Command in-position	Checks the remaining distance to the target position, and turns the command in-position flag to TRUE. The command in-position flag is used as a front-loading signal indicating beforehand the completion of the control.	Page 1059 Command In-position
Software stroke limit	Sets an address as the movable range. Even if a movement command to the address outside the setting range is issued, the command will not be executed. By not executing the command outside the movable area, even if an incorrect command or unexpected operation occurs, the system will not operate out of the movable area and damage to the machine can be prevented.	Page 1061 Software Stroke Limit
Hardware stroke limit	Sets a limit switch at the upper/lower limit of the physical movable range, and stops the control by the input of a signal from the limit switch. Damage to the machine can be prevented by stopping the control before the upper/lower limit of the physical movable range is reached.	Page 1069 Hardware Stroke Limit

34.1 Current Position Change Function

This function changes the set position and cumulative current position to any address.

- The current position change method includes a method of changing the set position at control execution (MC_SetPosition (Current Position Change)). (The machine feed value is not changed.)
- The "absolute position set" and the "relative position set" can be specified in the address to change.
- This function can be executed only while Axis Status (AxisName.Md.AxisStatus) is "4: Standby (Standstill)".
- A current position change to outside the ring counter range and outside the software stroke limit range cannot be executed.
- For operation when executing a current position change to the synchronous control master axis, refer to the following.

☞ Page 780 SYNCHRONOUS CONTROL

Point

When a current position change is completed, that "the current position change is executed" is recorded in the event history.

Targets to be changed and corresponding FBs

Target to be changed			Corresponding FB
Position	Current value		MC_SetPosition (Current Position Change)
	Limit value (Software stroke limit)		—*1
	Limit value (Software stroke limit)	Maximum value of the limit value	—*2

*1 Axis parameters can be changed by MC_WriteParameter (Parameter Write). However, they cannot be changed during control.

*2 The maximum value of the limit value cannot be changed.

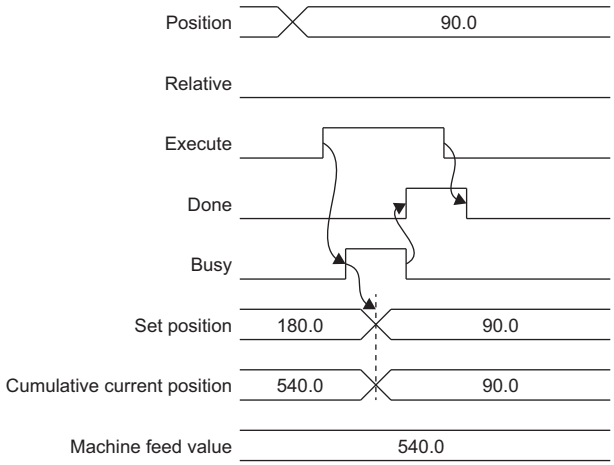
Relevant FB

For details on motion control FBs, refer to the following.

MELSEC MX Controller MX-R Model Programming Manual

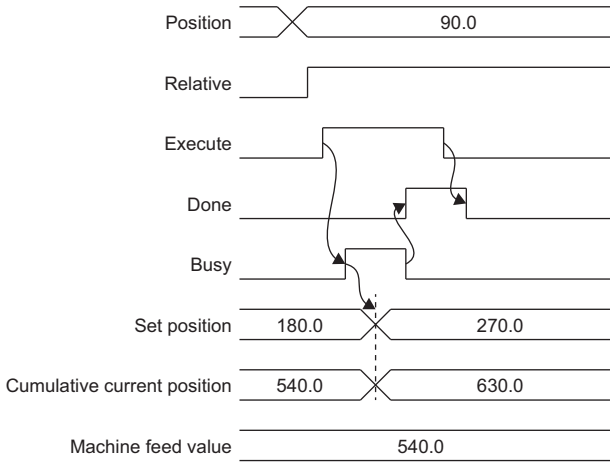
Motion control FB	Name	Description
MC_SetPosition	Current position change	Changes the current position of the specified axis (set position, actual position).

Current position change



The control details of current position change are shown below.

Execution when the axis stops



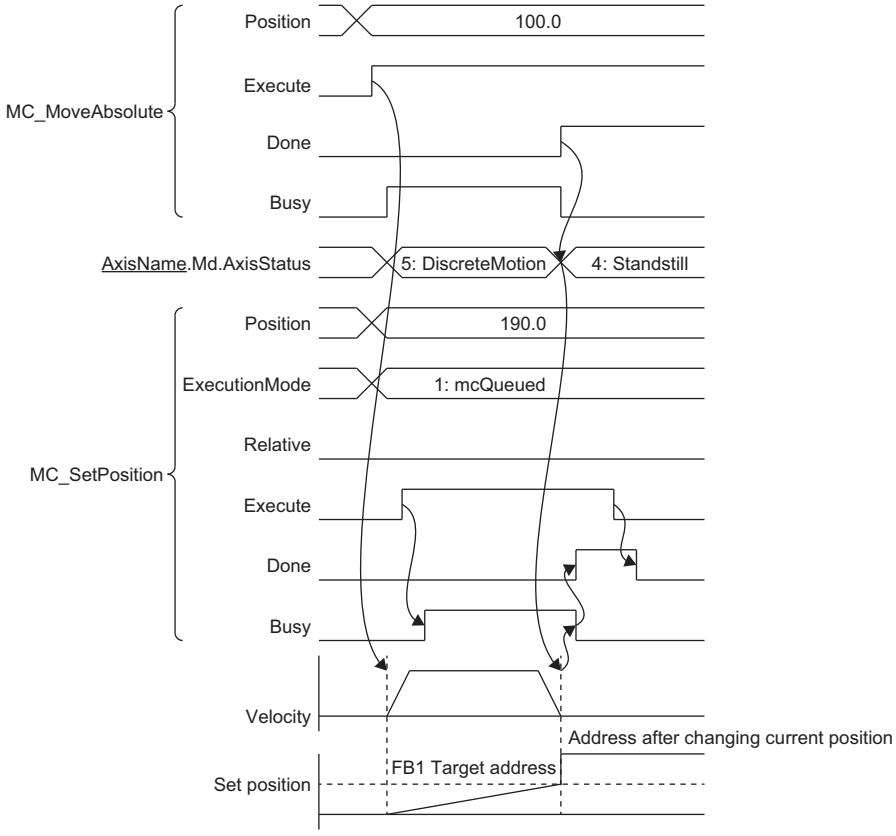
The current position change operation starts at rising edge detection of Execution command (Execute) of MC_SetPosition (Current Position Change).
In the current position change, the set position and the cumulative current position are changed to the position specified in Target position (Position).
Target position (Position) is "Relative position set" when Relative position selection (Relative) is TRUE, and it is "Absolute position set" when Relative position selection (Relative) is FALSE.

Ex.
When executing the current position change to 90.0 while the axis stops with the ring counter lower limit value of 0.0, the ring counter upper limit value of 360.0, and the set position of 180.0 (the cumulative current position of 540.0).

<When Relative position selection (Relative) is FALSE (Absolute position set)>

<When Relative position selection (Relative) is TRUE (Relative position set)>

Execution during axis operation

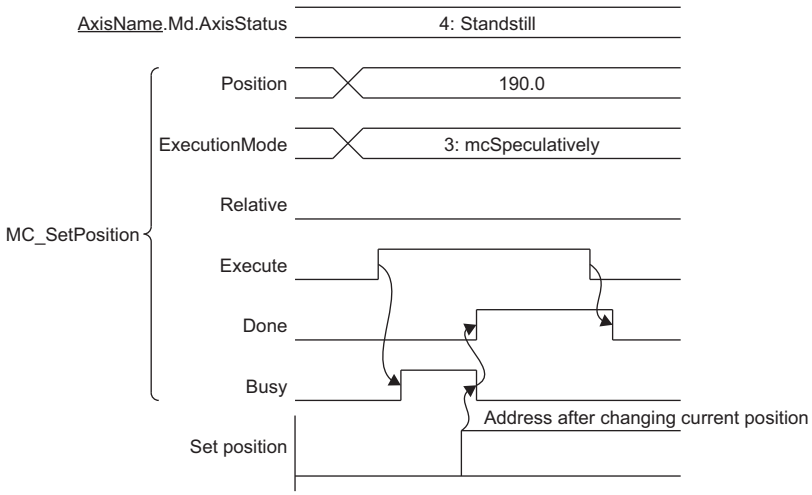


■Execute at Completion of Previous One

When "1: Execute at Completion of Previous One (mcQueued)" is set in Execution mode (ExecutionMode), this FB is executed after the on-going FB is completed.

At rising edge detection of Execution command (Execute), Executing (Busy) becomes TRUE and remains TRUE until Axis Status (AxisName.Md.AxisStatus) changes to "4: Standby (Standstill)".

As soon as Axis Status (AxisName.Md.AxisStatus) turns "4: Standby (Standstill)", the current position change operation will start.

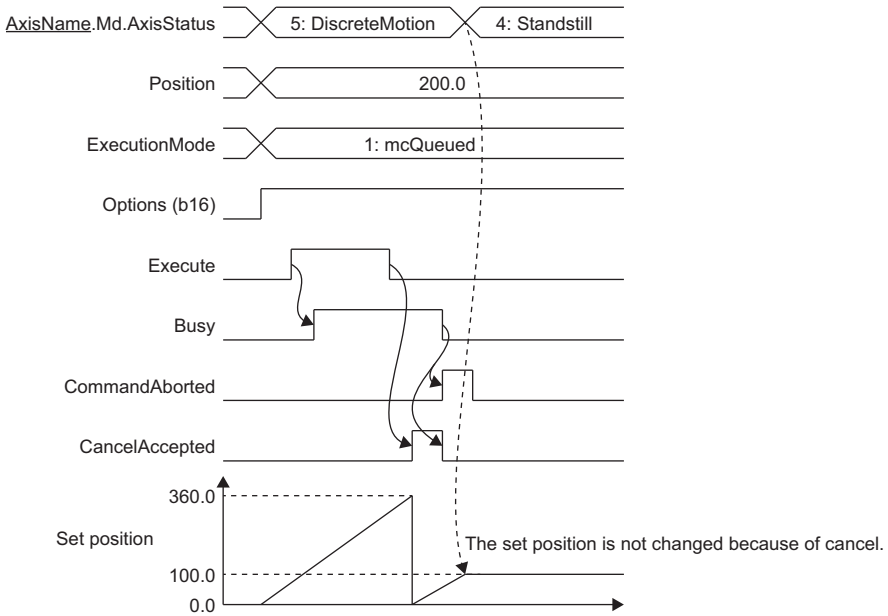


Ex.

■Speculative execution

When "3: Execute Speculatively (mcSpeculatively)" is specified to Execution mode (ExecutionMode), the current position change can be performed only when Axis Status (AxisName.Md.AxisStatus) of the relevant axis is "4: Standby (Standstill)" at the rising edge detection of Execution command (Execute). If Axis Status (AxisName.Md.AxisStatus) of the relevant axis is not "4: Standby (Standstill)", or FB instruction is being executed, MC_SetPosition instruction error (error code: 1B9CH) occurs, and the current position change is not performed.

Ex.



Cancel

Current position change that is in the standby status can be canceled after FB execution.

- To enable cancel, execute the FB with the status of Cancel accepted after FB start (Options (Options): bit 16) set to "1: Allow".
- Cancel is started at falling edge detection of Execution command (Execute).
- Cancel is accepted only when Executing (Busy) of the output pin is TRUE.
- When FB accepts cancel, Cancel acceptance (CancelAccepted) of the output pin becomes TRUE.
- When cancel is completed, Abortion of execution (CommandAborted) of the output pin becomes TRUE.
- When cancel was carried out, the set position is not changed.

Ex.

When canceling while Axis Status (AxisName.Md.AxisStatus) is waiting for switching to "4: Standby (Standstill)" after starting MC_SetPosition (Current Position Change) with Execution mode (ExecutionMode) set to "1: Execute at Completion of Previous One (mcQueued)"

34.2 Command In-position

This function checks the remaining distance to the target position, and turns the command in-position flag to TRUE.
The command in-position flag is used as a front-loading signal indicating beforehand the completion of the control.
The command in-position function is valid for all controls that require target address specification.
It changes Command In-position (AxisName.Md.CmdInPos) to TRUE when the remaining distance to the target position becomes Command In-position Width (AxisName.Md.CmdInPos_Width) or less.
It changes Command In-position (AxisName.Md.CmdInPos) to FALSE when the axis starts and when the FB is switched by multiple start.

Relevant variables

Axis parameter (AxisName.Pr.)

Variable/structure name	Name	Details
CmdInPos_Width	Command In-position Width	Sets the command in-position width. • 0.0: Function disabled • 0.000000001 to 10000000000.0: Function enabled*1

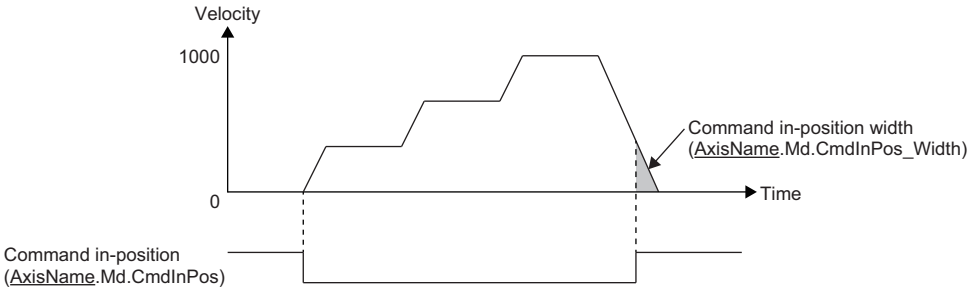
*1 When a positive number less than 0.000000001 is set, the value is imported as "0.0".

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
CmdInPos_Width	Command In-position Width	Displays the command in-position width. • The value is the one into which the setting value of Command In-position Width (AxisName.Pr.CmdInPos_Width) is imported. • When Command In-position Width (AxisName.Md.CmdInPos_Width) is "0.0", the command in-position function of the axis is disabled.
CmdInPos	Command In-position	Displays whether the remaining distance to the target position is Command In-position Width (AxisName.Md.CmdInPos_Width) or less. • FALSE: Command in-position width or more • TRUE: Command in-position width or less

Axes group parameter (AxesGroupName.Pr.)

Variable/structure name	Name	Details
CmdInPos_Width	Command In-position Width	Sets the command in-position width on the composite axis of the axes group. • 0.0: Function disabled • 0.000000001 to 10000000000.0: Function enabled*1



*1 When a positive number less than 0.000000001 is set, the value is imported as "0.0".

Axes group monitor data (AxesGroupName.Md.)

Variable/structure name	Name	Details
CmdInPos_Width	Command In-position Width	Displays the command in-position width on the composite axis of the axes group. • The value is the one into which the setting value of Command In-position Width (AxesGroupName.Pr.CmdInPos_Width) is imported. • When Command In-position Width (AxesGroupName.Md.CmdInPos_Width) is "0.0", the command in-position function of the axes group is disabled.
CmdInPos	Command In-position	Displays whether the remaining distance to the target position on the composite axis is Command In-position Width (AxesGroupName.Pr.CmdInPos_Width) or less. • FALSE: Command in-position width or more • TRUE: Command in-position width or less

Command in-position range check

A command in-position range check is carried out every operation cycle.
However, while the axis stops, Command In-position (AxisName.Md.CmdInPos) is not refreshed.
When Command In-position Width (AxisName.Md.CmdInPos_Width) is "0.0", a command in-position range check is not carried out.
For an axes group, the remaining distance on the composite axis (line/arc) is checked based on Command In-position Width (AxesGroupName.Md.CmdInPos_Width). When the long axis velocity specification and the reference axis velocity specification are used for linear interpolation control, the remaining distance on the long axis and the reference axis is checked.
The flag is stored in Command In-position (AxesGroupName.Md.CmdInPos).
During axes group operation, the command in-position function of the configuration axes is disabled. Command In-position (AxisName.Md.CmdInPos) of the configuration axes is not changed to TRUE during axes group operation. (It is changed to FALSE when the axes group is started.)

- (Remaining distance) ≤ (Command in-position width (AxisName.Md.CmdInPos_Width))

34.3 Software Stroke Limit

This function sets an address as the movable range. Even if a movement command to the address outside the setting range is issued, the command will not be executed.
By not executing the command outside the movable area, even if an incorrect command or unexpected operation occurs, the system will not operate out of the movable area and damage to the machine can be prevented.
In the motion system, the set position and machine feed value are used as the addresses indicating the current value. However, in the software stroke limit function, which address is used to perform the limit check is specified in Software Stroke Limit Target (AxisName.Pr.SwStrokeLimit_Target).

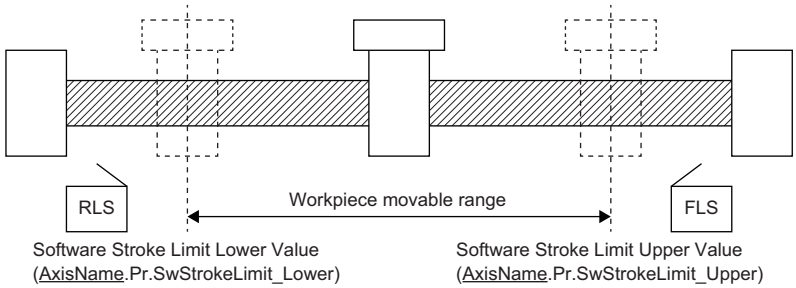
Relevant variables

Axis parameter (AxisName.Pr.)

Variable/structure name	Name	Details
SwStrokeLimit_Upper	Software Stroke Limit Upper Value	Sets the software stroke limit upper value. • -10000000000.0 to 10000000000.0
SwStrokeLimit_Lower	Software Stroke Limit Lower Value	Sets the software stroke limit lower value. • -10000000000.0 to 10000000000.0
SwStrokeLimit_Target	Software Stroke Limit Target	Sets the software stroke limit target. • -1: Invalid (Invalid) • 1: Set position (SetPosition) • 3: Machine feed value (FeedMachinePosition)

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
SwStrokeLimit_Upper	Software Stroke Limit Upper Value	Displays the software stroke limit upper value.
SwStrokeLimit_Lower	Software Stroke Limit Lower Value	Displays the software stroke limit lower value.
SwStrokeLimit_Target	Software Stroke Limit Target	Displays the software stroke limit check method target.
SwStrokeLimit_Override	Software Stroke Limit Override	Displays the software stroke limit valid/invalid status. • DISABLE: Check disabled • ONLY_INSIDE: Check disabled only for movement returning to the range • Other than the above: Check enabled (no disabling request)



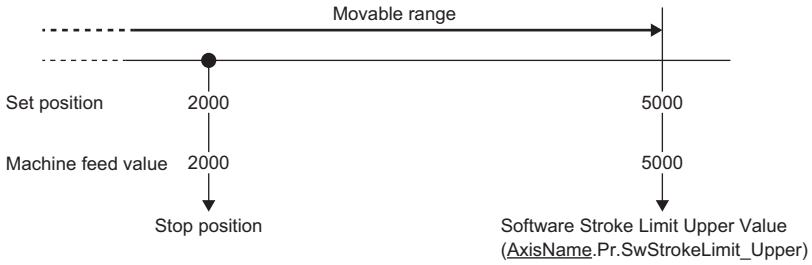
Axis control data (AxisName.Cd.)

Variable/structure name	Name	Details
SwStrokeLimit_Override	Software Stroke Limit Override	Temporarily switches whether to enable/disable the software stroke limit check. • DISABLE: Check disabled • ONLY_INSIDE: Check disabled only for movement returning to the range • Other than the above: Check enabled (no disabling request)

Definition of movable range

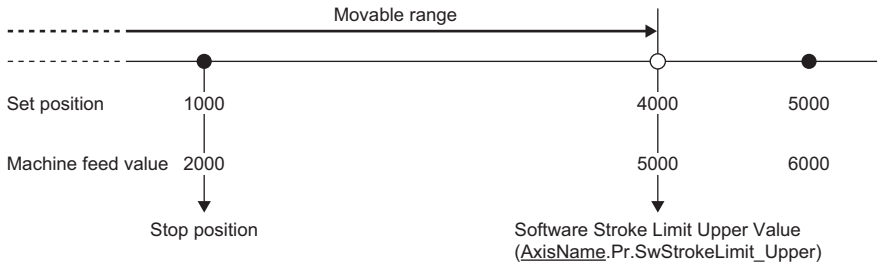
Movable range differences by selection of set position and machine feed value

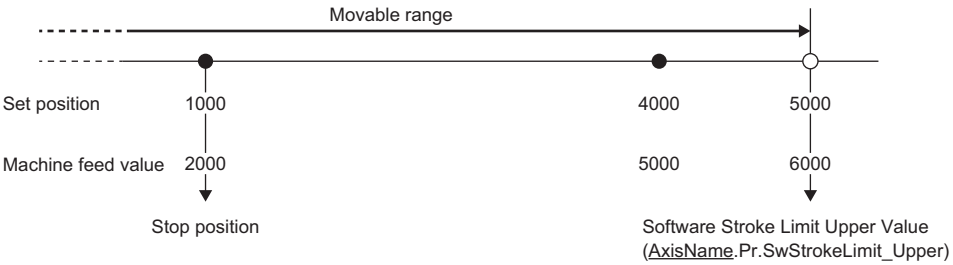
The following drawing shows the movable range of the workpiece when the software stroke limit function is used.



The set position or the machine feed value can be specified in the software stroke limit. (The cumulative current position cannot be specified.)

The following drawing shows the differences in the operation when the set position is used or when the machine feed value is used in the movable range limit check.





Ex.

When assuming that the current value is "2000", and Software Stroke Limit Upper Value (AxisName.Pr.SwStrokeLimit_Upper) is set to "5000".

- Current value changing

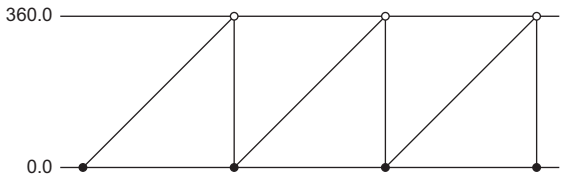
  When the current value is changed by a new current value command from 2000 to 1000, the set position will change to 1000, but the machine feed value will stay the same at 2000.

Setting	Description
When the machine feed value is set at the limit	The set position of "4000 (machine feed value: 5000)" becomes the upper stroke limit. 
When the set position is set at the limit	The set position of "5000 (machine feed value: 6000)" becomes the upper stroke limit. 

Point

When "3: Machine feed value (FeedMachinePosition)" is set in Software Stroke Limit Target (AxisName.Pr.SwStrokeLimit_Target), the movable range becomes an absolute range with respect to the home position.
When "1: Set Position (SetPosition)" is set, the movable range becomes the relative range from the set position.

■When selecting the set position when the ring counter is valid



- Set position

  The storing range of the set position is shown below.

Monitor data	Range
Set Position (AxisName.Md.SetPosition)	Ring counter lower limit value ≤ Set position < Ring counter upper limit value

Ex.

When the ring counter lower limit value is "0.0" and the ring counter upper limit value is "360.0"
The set position address becomes the ring address of "0.0 to 359.999...".

- Setting the software stroke limit

  The setting range of the software stroke limit upper/lower value is shown below.

Parameter	Setting range
Software Stroke Limit Upper Value (AxisName.Pr.SwStrokeLimit_Upper)	Ring counter lower limit value < Set value ≤ Ring counter upper limit value
Software Stroke Limit Lower Value (AxisName.Pr.SwStrokeLimit_Lower)	Ring counter lower limit value ≤ Set value < Ring counter upper limit value

Movable range: Software Stroke Limit Lower Value (AxisName.Pr.SwStrokeLimit_Lower) ≤ Set position < Software Stroke Limit Upper Value (AxisName.Pr.SwStrokeLimit_Upper)

• Details of the movable range

The movable range varies as shown below depending on the relationship between Software Stroke Limit Upper Value (AxisName.Pr.SwStrokeLimit_Upper) and Software Stroke Limit Lower Value (AxisName.Pr.SwStrokeLimit_Lower).

Movable range	Description
Software Stroke Limit Upper Value (AxisName.Pr.SwStrokeLimit_Upper) > Software Stroke Limit Lower Value (AxisName.Pr.SwStrokeLimit_Lower)	
Software Stroke Limit Upper Value (AxisName.Pr.SwStrokeLimit_Upper) < Software Stroke Limit Lower Value (AxisName.Pr.SwStrokeLimit_Lower)	
Software Stroke Limit Upper Value (AxisName.Pr.SwStrokeLimit_Upper) = Software Stroke Limit Lower Value (AxisName.Pr.SwStrokeLimit_Lower)	 • When the setting is "Set position = Software Stroke Limit Upper Value (AxisName.Pr.SwStrokeLimit_Upper) = Software Stroke Limit Lower Value (AxisName.Pr.SwStrokeLimit_Lower)", the set position is determined to be positioned at Software Stroke Limit Lower Value (position A in the above figure), and operation is possible within the "movable range" in the above figure.

■When selecting the set position or the machine feed value when the ring counter is invalid

- Machine feed value

  The storing range of the machine feed value is shown below.

Monitor data	Storing range
Machine Feed Value (AxisName.Md.FeedMachinePosition)	-10000000000.0 ≤ Machine Feed Value < 10000000000.0

- Setting the software stroke limit

  The setting range of the software stroke limit upper/lower value is shown below.

Parameter	Setting range
Software Stroke Limit Upper Value (AxisName.Pr.SwStrokeLimit_Upper)	Software Stroke Limit Lower Value (AxisName.Pr.SwStrokeLimit_Lower) < Setting value ≤ 10000000000.0
Software Stroke Limit Lower Value (AxisName.Pr.SwStrokeLimit_Lower)	-10000000000.0 ≤ Setting value < Software Stroke Limit Upper Value (AxisName.Pr.SwStrokeLimit_Upper)

Movable range: Software Stroke Limit Lower Value (AxisName.Pr.SwStrokeLimit_Lower) ≤ Set position < Software Stroke Limit Upper Value (AxisName.Pr.SwStrokeLimit_Upper)

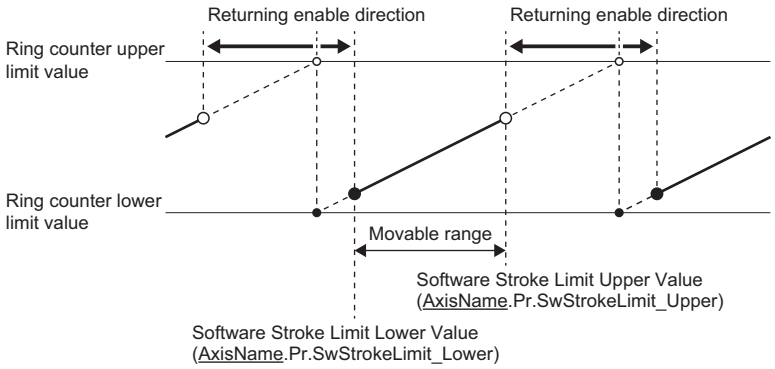
Invalidating the software stroke limit

To invalidate the software stroke limit, set "-1: Invalid (Invalid)" in Software Stroke Limit Target (AxisName.Pr.SwStrokeLimit_Target). By setting "-1: Invalid (Invalid)", the software stroke limit check is not executed in all controls regardless of the setting values of Software Stroke Limit Upper Value (AxisName.Pr.SwStrokeLimit_Upper) and Software Stroke Limit Lower Value (AxisName.Pr.SwStrokeLimit_Lower).

Returning from outside the software stroke limit range

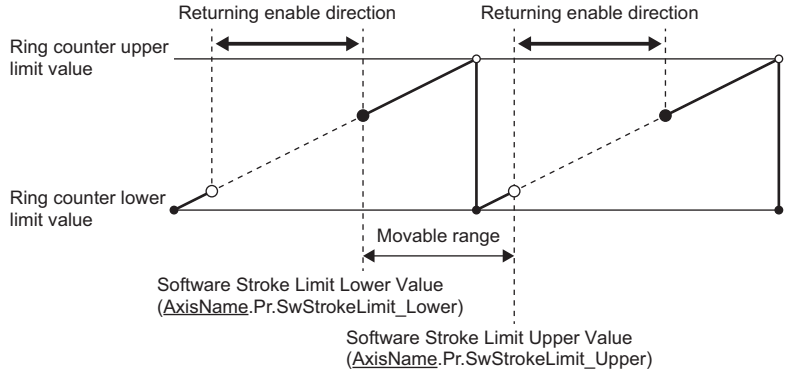
The axis cannot start outside the software stroke limit range while the software stroke limit is valid.
After setting "ONLY_INSIDE (Check disabled only for movement returning to the range)" or "DISABLE (Check disabled)" in Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit_Override), execute the axis operation to return to the movable range.
Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit_Override) is case-sensitive.

Point



- In Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit_Override), the software stroke limit can be temporarily disabled without changing the settings of Software Stroke Limit Upper Value (AxisName.Pr.SwStrokeLimit_Upper) and Software Stroke Limit Lower Value (AxisName.Pr.SwStrokeLimit_Lower).
- In Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit_Override), only the check in the returning enable direction can be disabled from outside the software stroke limit range. By disabling it only in the direction returning to the movable range, motions in unexpected directions can be prevented.
- If start or multiple start is performed while the software stroke limit is disabled by Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit_Override), "start while the software stroke limit is disabled" is recorded in the event history.

■Returning enable direction to the movable range



- When "ONLY_INSIDE (Check disabled only for movement returning to the range)" is set in Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit_Override), movement is allowed from outside the software stroke limit range to the movable range in the returning enable direction.
- The returning enable direction from outside the software stroke limit range means the direction in which the axis can return to the movable range without exceeding the ring counter value.
- If the axis operates in the direction so as to exceed the ring counter value from outside the software stroke limit range, Software stroke limit over (start position) (error code: 1A81H) or Software stroke limit over (target position) (error code: 1A80H) will be detected, and the axis will not start.
- Also, even if it is the returning enable direction, when a position which is outside the software stroke limit range exceeding the movable range is specified as the target position, Software stroke limit over (target position) (error code: 1A80H) will be detected, and the axis will not start.
- To return to the movable range ignoring the returning enable direction, set DISABLE (Check disabled) in Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit_Override) and perform a move to the movable range.

■Returning enable direction when setting "ONLY_INSIDE (Check disabled only for movement returning to the range)" in Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit_Override)

- When Software Stroke Limit Upper Value (AxisName.Pr.SwStrokeLimit_Upper) > Software Stroke Limit Lower Value (AxisName.Pr.SwStrokeLimit_Lower)

- When Software Stroke Limit Upper Value (AxisName.Pr.SwStrokeLimit_Upper) < Software Stroke Limit Lower Value (AxisName.Pr.SwStrokeLimit_Lower)

Checking the software stroke limit enabled/disabled

- In the Software Stroke Limit Override (AxisName.Md.SwStrokeLimit_Override), the software stroke limit check enabled/disabled status can be checked.
- Software Stroke Limit Override (AxisName.Md.SwStrokeLimit_Override) imports setting values of Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit_Override) when the status of PLC READY (MotionSystem.Cd.SequenceReady) is turned on, at start, or at multiple start, and updates as shown below.

Software Stroke Limit Target (AxisName.Pr.SwStrokeLimit_Target)	Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit_Override)	Software Stroke Limit Override (AxisName.Md.SwStrokeLimit_Override)
-1: Invalid (Invalid)	—	DISABLE: Check disabled
1: Set position (SetPosition) 3: Machine feed value (FeedMachinePosition)	Other than the following: No disabling request	Display is blank: No disabling request
	DISABLE: Check disabled	DISABLE: Check disabled
	ONLY_INSIDE: Check disabled only for movement returning to the range	ONLY_INSIDE: Check disabled only for movement returning to the range

Specifications of the software stroke limit check

The software stroke limit check is carried out at executing the motion FB and during control.

The following table shows the check details of the software stroke limit.

Check details	Check timing	Processing when an error occurs
An error shall occur if the target position is outside the software stroke limit range.	When executing the motion FB which has the "target position"	Software stroke limit over (target position) (error code: 1A80H) is output and the axis does not start.
An error shall occur if the start position is outside the software stroke limit range.	When executing the motion FB	Software stroke limit over (start position) (error code: 1A81H) is output and the axis does not start.
An error shall occur if the current value is outside the software stroke limit range during control.	During control	Software stroke limit over (forward direction) (error code: 1A83H) or Software stroke limit over (reverse direction) (error code: 1A84H) is output and the stop processing is executed.*1

*1 The error occurs when a command to a position outside the software stroke limit range is detected, and the stop processing is executed. To stop within the software stroke limit range, set to immediately stop.

The checking details of the following functions are different from the above.

- Homing control
- Multiple axes positioning data operation

For details, refer to the following.

☞ Page 617 HOMING

☞ Page 665 Multiple Axes Positioning Data Operation

Precautions

- Execute homing beforehand for the software stroke limit function to function properly.
- If Software stroke limit upper value (AxisName.Pr.SwStrokeLimit_Upper) or Software stroke limit lower value (AxisName.Pr.SwStrokeLimit_Lower) is outside the setting range, Out of parameter range (axis) (error code: 1A60H) will be detected.
- During interpolation control, the software stroke limit check is executed for all the current values of the interpolation control axes. When an error occurs in any axis, all axes will not start.
- When "3: Machine feed value (FeedMachinePosition)" is set as the setting value of Software Stroke Limit Target (AxisName.Pr.SwStrokeLimit_Target) to the axis type which does not have Machine Feed Value (AxisName.Md.FeedMachinePosition), Out of parameter range (axis) (error code: 1A60H) will be detected.

34.4 Hardware Stroke Limit

This function sets a limit switch at the upper/lower limit of the physical movable range, and stops the control by the input of a signal from the limit switch.
Damage to the machine can be prevented by stopping the control before the upper/lower limit of the physical movable range is reached.

⚠WARNING

- The negative logic (normally closed contact) is recommended for wiring the hardware stroke limit. If the positive logic (normally open contact) is used, a serious accident may occur when disconnection or sensor failure occurs.
- To use the hardware stroke limit function, the add-on ExternalSignal must be valid. When the add-on is not installed or invalid, the axis does not stop and an error is not output even if the signal is input.

For details on the signals that can be used in the hardware stroke limit, refer to the following.
☞ Page 1154 EXTERNAL SIGNAL SELECTION

Operation of this function for each system status

○: Available, ×: Not available

System status	Operation availability
STOP	○
RUN	○
Moderate error	○*1
Major error	○*1

*1 FLS/RLS signals may not be sent depending on the error.
When a moderate or major error occurs, the motion system notifies the device station that an error has been detected in the CPU operating status.
For operation of the device station when an error is detected, refer to the manual for each device station.

Relevant variables

Axis parameter constant (AxisName.PrConst.)

Variable/structure name	Name	Details
HwStrokeLimit_FlsSignal	Upper Limit Signal	Sets a signal that uses the upper limit signal (FLS). Upper limit signal (HwStrokeLimit_FlsSignal) is the structure of SIGNAL_SELECT type. The fetch timing of the label is at the system start, and the detection timing of the signal is the axis operation cycle. For details on SIGNAL_SELECT type, refer to the following. ☞ Page 1156 SIGNAL_SELECT Structure It may be regarded as signal detection depending on the variable used as an external signal and the status of devices controlled by the controller. For details, refer to the following. ☞ Page 1154 EXTERNAL SIGNAL SELECTION The specific setting and the operation of this signal are shown below. ■I/O Number (StartIO) Ignores the input value. ■Target (Target) When the specification is not set, signal disabled is determined and the signal not detecting status is always set. Hardware Stroke Limit Override (AxisName.Md.HwStrokeLimit_Override) is not imported. Only [VAR], [DEV], and [CONST] can be specified for data type. * If an unavailable value is set, Out of parameter range (axis) (error code: 1A60H) occurs. The error cause can be checked with the following detail codes. • An incorrect string was set (detail code: 0001H) • An unavailable data type was set (detail code: 0002H) • An unavailable type was specified (detail code: 0003H) • A type other than the numerical value type was specified at label specification (detail code: 0004H) • A signal that does not exist was set (detail code: 0005H) • A global label where access from an external device is disabled was set (detail code: 0005H) • The number of characters exceeded the upper limit (detail code: 0007H). • "Asynchronous" was set in the network synchronous communication setting of the device station being referred to (detail code: 8002H) • An unsupported device was set (detail code: 8002H) • A device number out of range was set (detail code: 8002H) ■Signal Detection Method (Detection) The specification is allowed at the following level detection only. • 0: Detection at TRUE (HighLevel) • 1: Detection at FALSE (LowLevel) * When a value outside the range is set, Out of parameter range (axis) (error code: 1A60H) (detail code: 8003H) occurs. ■Compensation Time (CompensationTime) Ignores the input value. ■Filter Time (FilterTime) The setting range is from 0.0 to +5.0 [s]. * When a value outside the range is set, Out of Filter Time Setting Range of Each Axis Signal Warning (event code: 00D24H) occurs, and the axis operates with 0.0 of the filter time.

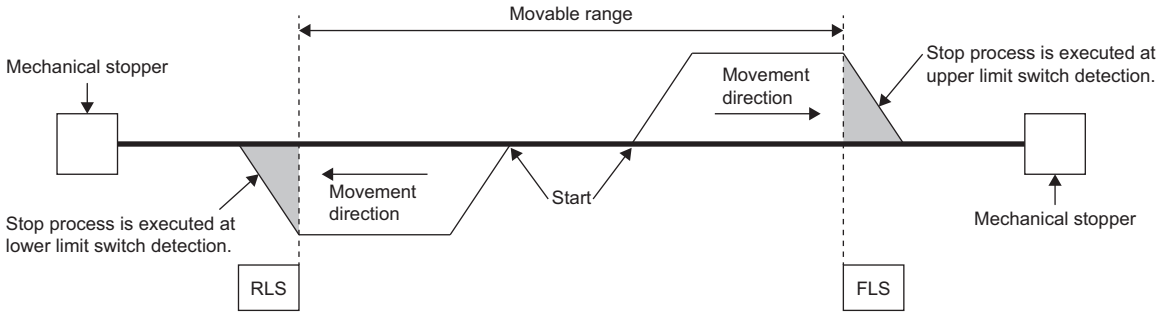
Variable/structure name	Name	Details
HwStrokeLimit_RlsSignal	Lower Limit Signal	Sets a signal that uses the lower limit signal (RLS). Lower limit signal (HwStrokeLimit_RlsSignal) is the structure of SIGNAL_SELECT type. The fetch timing of the label is at the system start, and the detection timing of the signal is the axis operation cycle. For details on SIGNAL_SELECT type, refer to the following. ☞ Page 1156 SIGNAL_SELECT Structure It may be regarded as signal detection depending on the variable used as an external signal and the status of devices controlled by the controller. For details, refer to the following. ☞ Page 1154 EXTERNAL SIGNAL SELECTION The specific setting and the operation of this signal are shown below. ■I/O Number (StartIO) Ignores the input value. ■Target (Target) When the specification is not set, signal disabled is determined and the signal not detecting status is always set. Control data is not imported. Only [VAR], [DEV], and [CONST] can be specified for data type. * If an unavailable value is set, Out of parameter range (axis) (error code: 1A60H) occurs. The error cause can be checked with the following detail codes. • An incorrect string was set (detail code: 0001H) • An unavailable data type was set (detail code: 0002H) • An unavailable type was specified (detail code: 0003H) • A type other than the numerical value type was specified at label specification (detail code: 0004H) • A signal that does not exist was set (detail code: 0005H) • A global label where access from an external device is disabled was set (detail code: 0005H) • The number of characters exceeded the upper limit (detail code: 0007H). • "Asynchronous" was set in the network synchronous communication setting of the device station being referred to (detail code: 8002H) • An unsupported device was set (detail code: 8002H) • A device number out of range was set (detail code: 8002H) ■Signal Detection Method (Detection) The specification is allowed at the following level detection only. • 0: Detection at TRUE (HighLevel) • 1: Detection at FALSE (LowLevel) * When a value outside the range is set, Out of parameter range (axis) (error code: 1A60H) (detail code: 8003H) occurs. ■Compensation Time (CompensationTime) Ignores the input value. ■Filter Time (FilterTime) The setting range is from 0.0 to +5.0 [s]. * When a value outside the range is set, Out of Filter Time Setting Range of Each Axis Signal Warning (event code: 00D24H) occurs, and the axis operates with 0.0 of the filter time.

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
HwStrokeLimit_FlsStatus	Upper Limit Signal Status	Displays the detection status of the upper limit signal (FLS). • FALSE: Not detecting the upper limit signal (FLS) • TRUE: Detecting the upper limit signal (FLS) * Displays the detection state in which the signal detection method and the filter time are reflected but not the signal input state.
HwStrokeLimit_RlsStatus	Lower Limit Signal Status	Displays the detection status of the lower limit signal (RLS). • FALSE: Not detecting the lower limit signal (RLS) • TRUE: Detecting the lower limit signal (RLS) * Displays the detection state in which the signal detection method and the filter time are reflected but not the signal input state.
HwStrokeLimit_Override	Hardware Stroke Limit Override	Displays the acceptance status of the command to switch enable/disable of the hardware stroke limit check. • DISABLE: Check disabled • ONLY_INSIDE: Check disabled only for movement returning to the range • Other than the above: Check enabled (no disabling request)

Axis control data (AxisName.Cd.)

Variable/structure name	Name	Details
HwStrokeLimit_Override	Hardware Stroke Limit Override	Switches enable/disable of the hardware stroke limit check. • DISABLE: Check disabled • ONLY_INSIDE: Check disabled only for movement returning to the range • Other than the above: Check enabled (no disabling request)



Hardware stroke limit check details

The check of hardware stroke limit range is carried out during executing and controlling the motion FB.

The following table shows the check details of the hardware stroke limit.

Check details	Check timing	Processing when an error occurs
Signal input from the upper limit signal (FLS) is detected at start.	At start	FLS signal detection (at start) (error code: 1A9EH) occurs and the axis does not start.
Signal input from the lower limit signal (RLS) is detected at start.	At start	RLS signal detection (at start) (error code: 1A9FH) occurs and the axis does not start.
Signal input from the upper limit signal (FLS) is detected during control.	During control	FLS signal detection (controlling) (error code: 1AA0H) occurs and the axis stops.*1
Signal input from the lower limit signal (RLS) is detected during control	During control	RLS signal detection (controlling) (error code: 1AA1H) occurs and the axis stops.*1

*1 The axis stops according to the stop processing.

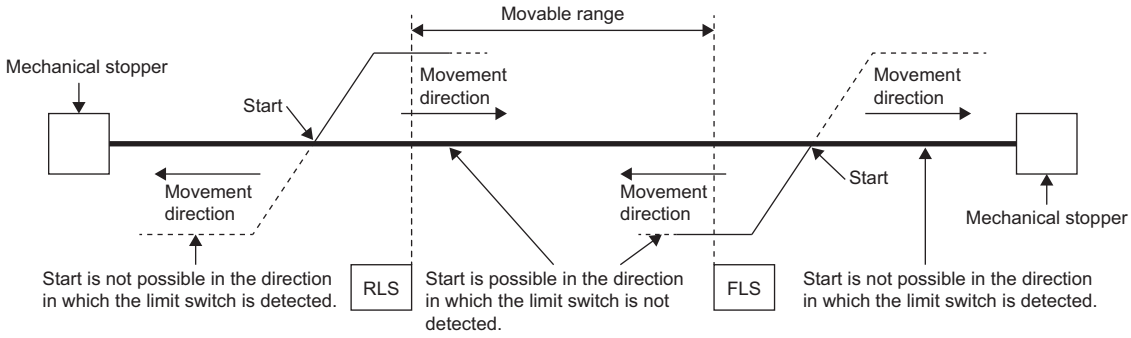
Point

While the limit switch is detected, the operation cannot be performed regardless of the detection direction/ movement direction.

Returning from outside the hardware stroke limit range

While the limit switch is detected, the operation cannot be started regardless of the detection direction.
After setting "ONLY_INSIDE (Check disabled only for movement returning to the range)" or "DISABLE (Check disabled)" in Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit_Override), execute the axis operation to return to the controllable range.

Point



- When an item other than "ONLY_INSIDE (Check disabled only for movement returning to the range)" and "DISABLE (Check disabled)" is set in Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit_Override), the axis operates with "No disabling request".
  Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit_Override) is case-sensitive.
- If start or multiple start is performed while the hardware stroke limit is disabled by Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit_Override), "start while hardware stroke limit is disabled" is recorded in the event history.

Precautions

Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit_Override) is valid only in the hardware stroke limit processing on the controller side. The stroke limit processing on the drive unit side is not affected by Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit_Override).

When setting ONLY_INSIDE (Check disabled only for movement returning to the range)

The axis can start in the direction in which the limit switch has not been detected.

When setting DISABLE (Check disabled)

The axis can start regardless of the limit switch detection status.

Checking whether the hardware stroke limit is enabled/disabled

- In the Hardware Stroke Limit Override (AxisName.Md.HwStrokeLimit_Override), the hardware stroke limit check enabled/disabled status can be checked.
- Hardware Stroke Limit Override (AxisName.Md.HwStrokeLimit_Override) imports the setting value of Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit_Override) at start or at multiple start, and updates as shown below.

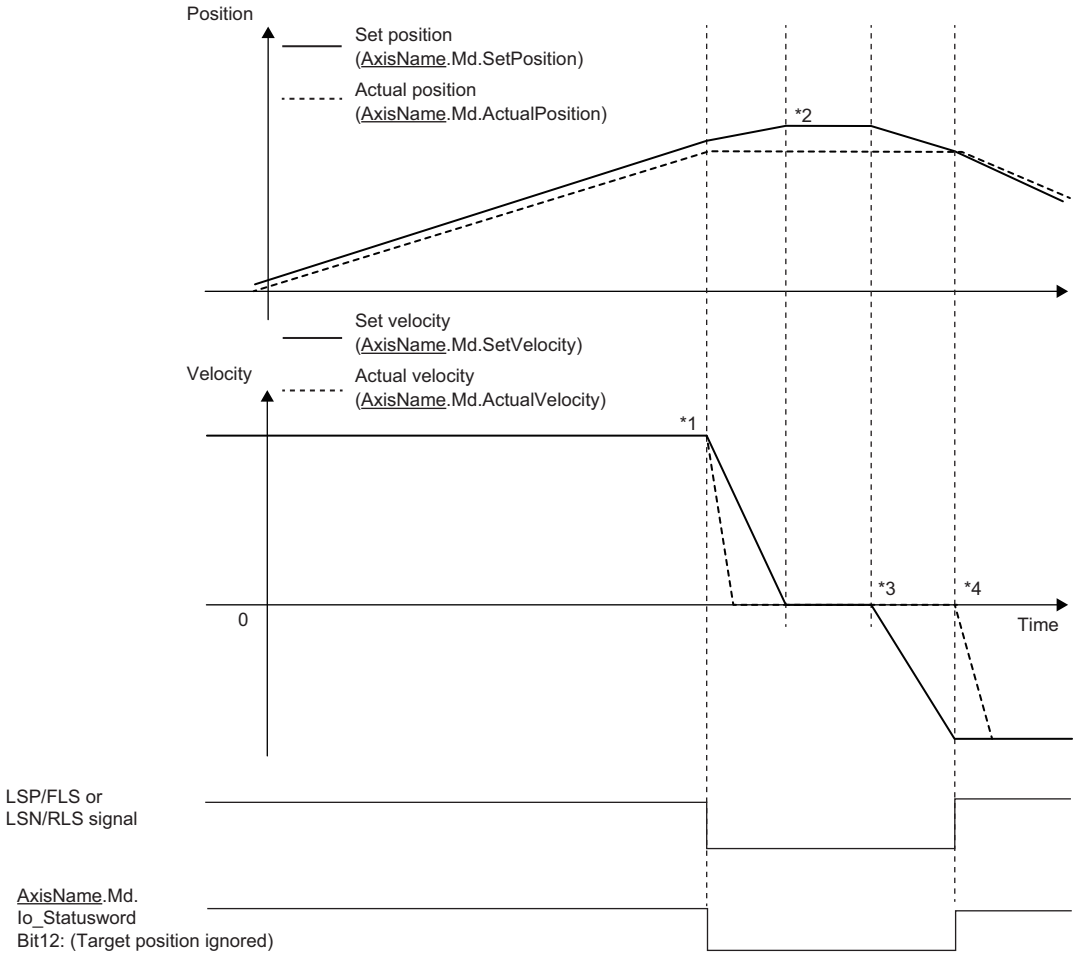
Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit_Override)	Hardware Stroke Limit Override (AxisName.Md.HwStrokeLimit_Override)
DISABLE (Check disabled)	DISABLE (Disabling hardware stroke limit check)
ONLY_INSIDE (Check disabled only for movement returning to the range)	ONLY_INSIDE (Disabling hardware stroke limit check only for movement returning to the range)
Other than the above	No display (No disabling request. Hardware stroke limit check is enabled.)

Precautions

- Install the upper limit signal (FLS) in the direction in which the set position increases, and install the lower limit signal (RLS) in the direction in which the set position decreases. If inverting the install positions of the upper limit signal (FLS)/lower limit signal (RLS), hardware stroke limit function cannot be operated properly.
- The upper limit signal (FLS) and lower limit signal (RLS) detected on the controller can be sent to the servo amplifier. For details on the setting method at connecting the MR-J5(W)-G, refer to the following.
  ☞ Page 2155 How to use

Point

- The controller sends the signals as "FALSE: Detecting the signal", "TRUE: Not detecting the signal" to the servo amplifier. Therefore, the servo amplifier side must be set by using "the negative logic (normally closed contact)" to receive the signal.
- When labeling the data sent from the controller, the sent data is overwritten with the label value and the detection state cannot be sent to the servo amplifier. To send the data to the servo amplifier, do not label the data.



- The LSP/LSN signal input to the servo amplifier when connecting to the MR-J5(W)-G can be set as the hardware stroke limit signal. For details on the setting method, refer to the following.
  ☞ Page 2155 How to use
- When the MR-J5(W)-G is connected, the operation differs at LSP/FLS or LSN/RLS signal detection depending on the setting of "Limit switch enabled status selection (PD41.2)" of the servo parameter "Function selection D-4 (PD41)".

Setting	Operation
When "0: Limit switch always enabled"	The drive unit side executes the stop processing, and then turns to servo-lock status (Statusword Bit12: off) and the drive unit will ignore the motion system command. The motion system can stop the command by enabling Driver Command Discard Detection Setting (AxisName.Pr.StopOption_DriverTargetIgnored).
When "1: Enabled only for homing mode" or the drive unit is in Homing mode	The drive unit side will execute the stop processing. When the drive unit is in a mode other than Homing mode, the signal will be ignored. Therefore, set it to stop by the motion system using the hardware stroke limit function.

- When "Limit switch enabled status selection (PD41.2)" of servo parameter "Function selection D-4 (PD41)" is "0: Limit switch always enabled", the stop will be executed ignoring the command from the motion system at limit switch detection. Therefore, when using the MR-J5(W)-G, it is recommended to set "1: Enabled only for homing mode", and "Sensor input method selection (PD41.3)" to "1: Input from controller".
  When setting "0: Limit switch always enabled", the command on the controller side needs to be stopped. Be sure to enable Driver Command Discard Detection Setting (AxisName.Pr.StopOption_DriverTargetIgnored).
  The example of operation is shown below.

Ex.

When detecting a limit signal at the drive unit side

*1 When the LSP/FLS or LSN/RLS signal is detected, the stop process is executed by the drive unit. When Driver Command Discard Detection Setting (AxisName.Pr.StopOption_DriverTargetIgnored) is enabled, the motion system will detect Driver command discard detection (error code: 1B18H) and execute the command stop. For details on the setting, refer to the following.
☞ Page 578 Stop

*2 After completion of the stop process on the motion system side, it stops with the status where Actual Position (AxisName.Md.ActualPosition) deviates from Set Position (AxisName.Md.SetPosition). (The position command from the motion system to the outside of the stroke limit is ignored in the drive unit.)

*3 After the stop, when axis control is performed in the direction toward the inside of the stroke limit, the position command (the set position and machine feed value) and command velocity of the motion system are updated. However, the servo motor does not operate.

*4 When the position command from the motion system becomes "the command position where the LSP/FLS or LSN/RLS signal is detected", the servo motor starts the operation to the inside of the stroke limit.

Point

- To stop while holding the relation between the master axis and the slave axis of the axes group and the synchronous control when detecting the stroke limit of the drive unit, set "Limit switch enabled status selection (PD41.2)" of the servo parameter "Function selection D-4 (PD41)" to "1: Enabled only for homing mode".
- When the signal is turned on (limit signal OFF) in the status where the actual position deviates from the position command with the stop by the stroke limit detection of the drive unit, the motor makes rapid movement to the position command of the motion system. Restore the deviation between the actual position and the position command by axis control to the inside of the stroke limit. (Set the servo OFF status, so that restoring the position command to the actual position by follow up is possible. After the restoration, set the servo ON again and move the motor to the inside of the stroke limit with the axis control.)
- When the position command of the motion system stops on the stroke limit side closer than the actual position by the stroke limit detection of the drive unit and the axis control is performed toward the inside of the stroke limit, the actual position follows the set position from the motion system.

Relevant add-ons

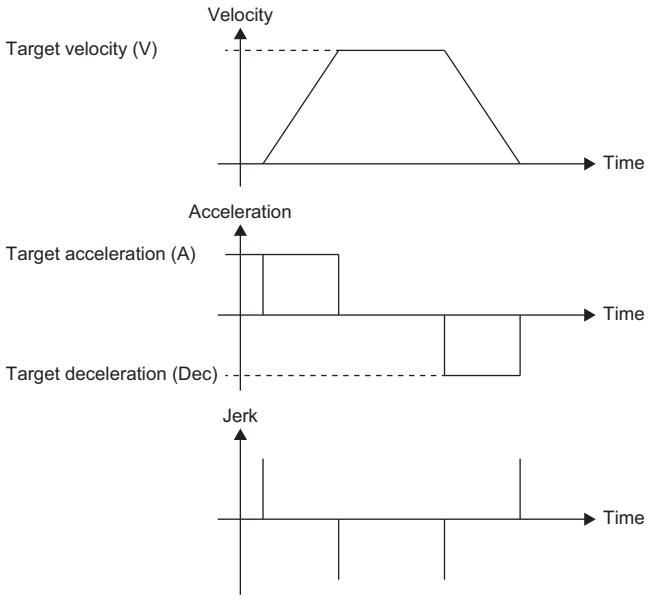
35 FUNCTIONS RELATED TO VELOCITY

The functions related to velocity have the following items.

Item	Description	Reference
Acceleration/Deceleration Processing Function	Adjusts the acceleration/deceleration of each motion control to the acceleration/deceleration curve suitable for device.	Page 1078 Acceleration/Deceleration Processing Function
Velocity limit	Limits the command velocity to a value within the speed limit value setting range when the command velocity during control exceeds the speed limit value. By limiting the command velocity within the preset velocity limit value range, even if an incorrect command or unexpected operation occurs, damage to the machine can be prevented.	Page 1112 Velocity Limit
Override function	Changes the target velocity and the target acceleration/deceleration during the execution of the control by setting the override coefficient.	Page 1116 Override Function

35.1 Acceleration/Deceleration Processing Function

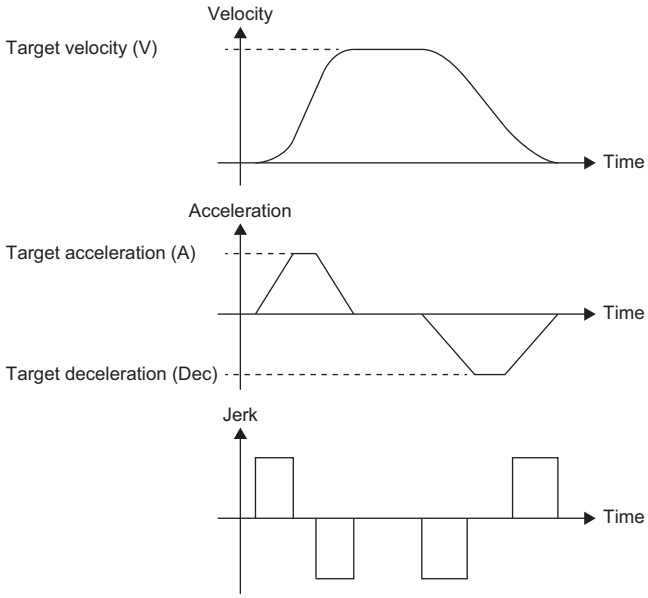
This function adjusts the acceleration/deceleration of each motion control to the acceleration/deceleration curve suitable for device.



Acceleration/deceleration method

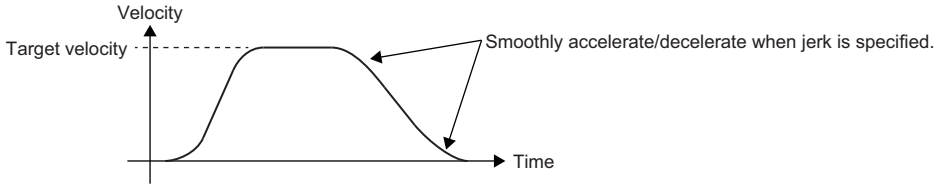
The following methods can be selected for the acceleration/deceleration method. When a value outside the range is set in the acceleration/deceleration method, Out of acceleration/deceleration method range (error code: 1AF8H) will occur and the axis will not start.

Acceleration/deceleration method	Description
Acceleration/deceleration specification method (Default)	An acceleration/deceleration method using Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk) specified in the FB.
Acceleration/deceleration time-fixed method	An acceleration/deceleration method using the acceleration/deceleration time specified in the FB regardless of the velocity.



■Trapezoidal acceleration/deceleration

When "0.0" is set in the jerk, the curve is called the trapezoidal acceleration/deceleration. The velocity shows a trapezoidal waveform.

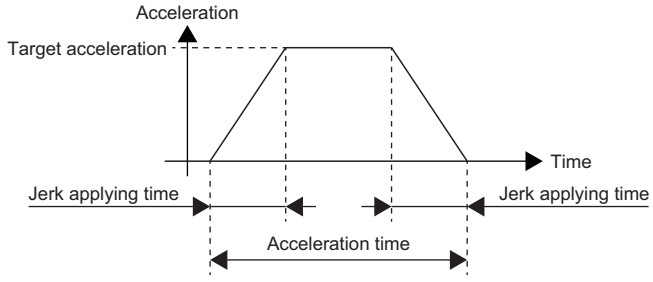


■Jerk acceleration/deceleration

When a value other than "0.0" is set in the jerk, the curve is called the jerk acceleration/deceleration. The velocity shows an S-shaped waveform.

Jerk

Jerk is the temporal change ratio of the acceleration or deceleration. The unit is "command unit (U)/s^3". When the jerk is set, since the velocity waveform shows a S-shape and the axis can smoothly accelerate and decelerate at the start and the end of acceleration and deceleration, it can reduce the burden on the motor and impact on the machine.



■Jerk applying time/Jerk applying ratio

The sum of the time required to reach the target acceleration after startup and the time from the target acceleration to the acceleration 0 at the end of acceleration is called the jerk applying time. The ratio of jerk applying time to acceleration (deceleration) time is called the jerk applying ratio.

The jerk applying time and the jerk applying ratio can be calculated with the following formula.

Item	Expression
Jerk applying time	2 × Target Acceleration ÷ Jerk
Jerk applying ratio	(Jerk applying time ÷ Acceleration time) × 100 [%]

Relevant variables

Axis parameter (AxisName.Pr.)

Variable/structure name	Name	Details
VelocityLimit_Positive	Positive Direction Velocity Limit Value	Sets the positive direction velocity limit value. For details, refer to the following. ☞ Page 1112 Velocity Limit

*1 When a positive number less than 0.0001 is set, the value is imported as "0.0000".

Axis monitor data (AxisName.Md.)

Variable/structure name	Name	Details
CommandedAcceleration	Commanded Acceleration	Stores the acceleration specified by users. (Unit: U/s^2) When "1: Acceleration/deceleration time-fixed method (mcFixedTime)" is set in the acceleration/deceleration method, it stores the specified acceleration/deceleration time. (Unit: s) During axes group operation, it stores "0.0" in Commanded Acceleration (AxisName.Md.CommandedAcceleration) of the configuration axis.
CommandedDeceleration	Commanded Deceleration	Stores the deceleration specified by users. (Unit: U/s^2) When the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)", it is an illegal value. During axes group operation, it stores "0.0" in Commanded Deceleration (AxisName.Md.CommandedDeceleration) of the configuration axis.
TargetAcceleration	Target Acceleration	Stores the acceleration that is maximum during acceleration. (Unit: U/s^2) During axes group operation, it stores "0.0" in Target Acceleration (AxisName.Md.TargetAcceleration) of the configuration axis.
TargetDeceleration	Target Deceleration	Stores the deceleration that is maximum during deceleration. (Unit: U/s^2) During axes group operation, it stores "0.0" in Target Deceleration (AxisName.Md.TargetDeceleration) of the configuration axis.
SetAcceleration	Set Acceleration	Stores the command output acceleration. It is the acceleration/deceleration calculated from the difference of set velocity. (Unit: U/s^2)*1 Depending on the direction of movement and the value of Set Acceleration (AxisName.Md.SetAcceleration), the acceleration and deceleration status varies. ■The movement direction is the positive direction (address increasing direction) • 0.0: During stop or fixed-speed • Positive value: During acceleration • Negative value: During deceleration ■The movement direction is the negative direction (address decreasing direction) • 0.0: During stop or fixed-speed • Positive value: During deceleration • Negative value: During acceleration "0.0" is stored when the target velocity is reached. During axes group operation, it stores the set acceleration of the configuration axis.
CommandedJerk	Commanded Jerk	Stores the jerk specified by users. (Unit: U/s^3) During axes group operation, it stores "0.0" in Commanded Jerk (AxisName.Md.CommandedJerk) of the configuration axis.
InVelocity	Target Velocity Reached	Displays whether the set velocity has reached the target velocity or not. During axes group operation, it stores FALSE in Target Velocity Reached (AxisName.Md.InVelocity) of the configuration axis. • FALSE: Not reached • TRUE: Reached
AutoDeceleration	Automatically Decelerating	Displays the status of auto deceleration processing. TRUE is stored while the auto deceleration processing is being executed. When the multiple start is executed, TRUE is set while the auto deceleration processing is executed during the last positioning point execution. FALSE is set when the control change is performed. During axes group operation, it stores FALSE in Automatically Decelerating (AxisName.Md.AutoDeceleration) of the configuration axis. • FALSE: Not during auto deceleration • TRUE: During auto deceleration
VelocityBias	Velocity bias value	The setting value of the velocity bias value (AxisName.Pr.VelocityBias) imported at ready ON is stored.

*1 The stored value includes an error because a floating-point error occurs.

Axes group monitor data (AxesGroupName.Md.)

Variable/structure name	Name	Details
CommandedAcceleration	Commanded Acceleration	Stores the acceleration specified by users. (Unit: U/s^2) When "1: Acceleration/deceleration time-fixed method (mcFixedTime)" is set in the acceleration/deceleration method, it stores the specified acceleration/deceleration time. (Unit: s)
CommandedDeceleration	Commanded Deceleration	Stores the deceleration specified by users. (Unit: U/s^2) When the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)", it is an illegal value.
TargetAcceleration	Target Acceleration	Stores the acceleration that is maximum during acceleration. (Unit: U/s^2)
TargetDeceleration	Target Deceleration	Stores the deceleration that is maximum during deceleration. (Unit: U/s^2)
SetAcceleration	Set Acceleration	Stores the command output acceleration. It is the acceleration/deceleration calculated from the difference of set velocity. (Unit: U/s^2)*1 The value is positive when the acceleration changes in the positive direction (address increasing direction), and the value is negative when the acceleration changes in the negative direction (address decreasing direction).
CommandedJerk	Commanded Jerk	Stores the jerk specified by users. (Unit: U/s^3)
InVelocity	Target Velocity Reached	Displays whether the set velocity has reached the target velocity or not. • FALSE: Not reached • TRUE: Reached
AutoDeceleration	Automatically Decelerating	Displays the status of auto deceleration processing. TRUE is stored while the auto deceleration processing is being executed. When the multiple start is executed, TRUE is set while the auto deceleration processing is executed during the last positioning point execution. FALSE is set when the control change is performed. • FALSE: Not during auto deceleration • TRUE: During auto deceleration
VelocityBias	Velocity bias value	The setting value of the velocity bias value (AxesGroupName.Pr.VelocityBias) imported at ready ON is stored.

*1 The stored value includes an error because a floating-point error occurs.

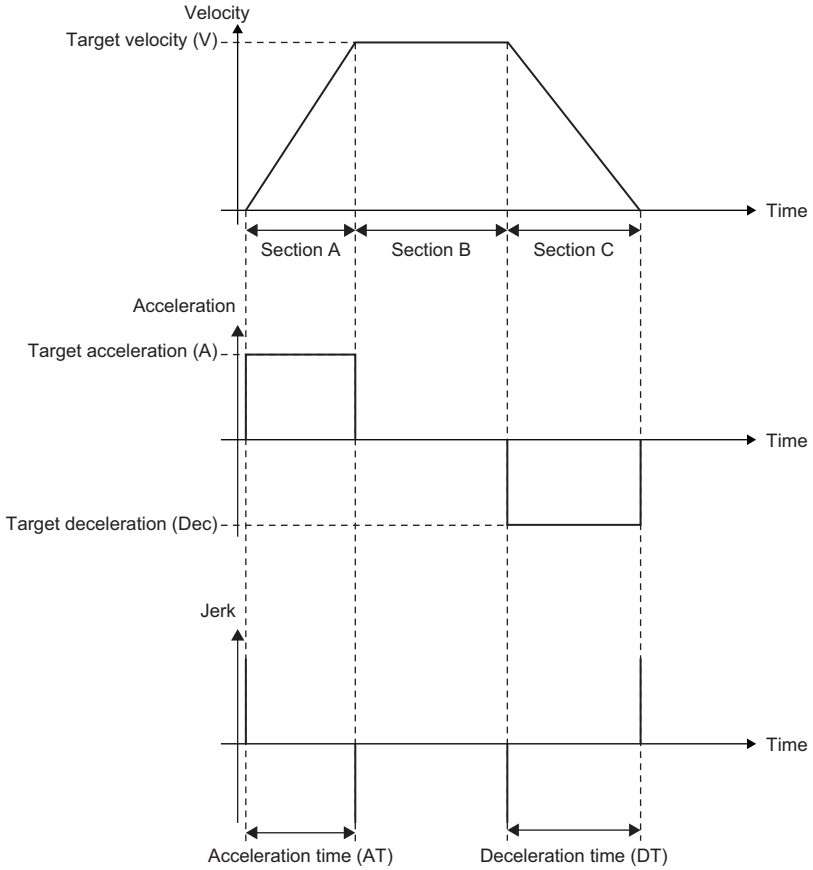
Settings of motion FB

The acceleration/deceleration method can be selected in "bits 0 to 2" of Options (Options) of the motion FB.

The details of the bits are shown below.

Bit	Function description
0 to 2	Acceleration/deceleration method setting • 0: Acceleration/deceleration specification method (mcAccDec) • 1: Acceleration/deceleration time-fixed method (mcFixedTime) For details, refer to the following. ☞ Page 1078 Acceleration/deceleration method

Whether a method can be selected or not differs depending on the FB. For details, refer to the following.



MELSEC MX Controller MX-R Model Programming Manual

Acceleration/deceleration method

Acceleration/deceleration specification method

When "0: Acceleration/deceleration specification method (mcAccDec)" is selected in the Acceleration/deceleration method setting (Options (Options) bits 0 to 2) of the FB, set the acceleration, deceleration, and jerk.

■Trapezoidal acceleration/deceleration

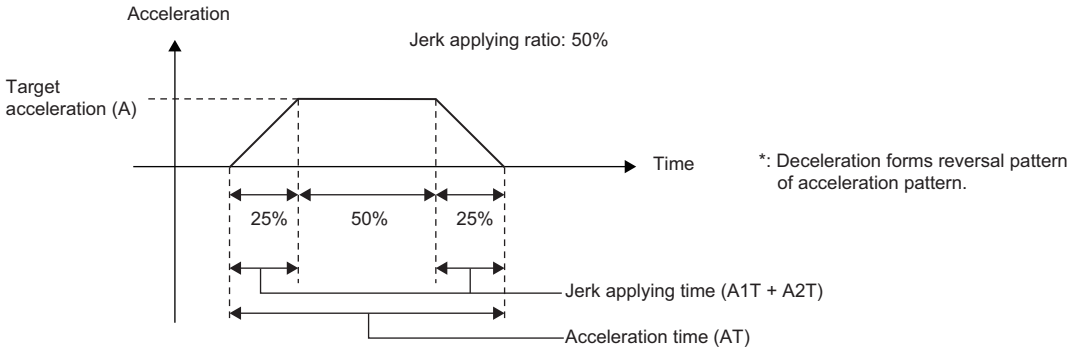
	Deceleration time*2	DT	Time to decelerate from the target velocity to the velocity 0.0	D1T + D2T + D3T = (V ÷ Dec) + (Dec ÷ J)*3	×	○



*1 Target acceleration/target deceleration may be adjusted by acceleration/deceleration waveform adjustment. For details, refer to the following.
☞ Page 1092 Acceleration/deceleration waveform adjustment when specifying jerk
*2 Acceleration time and deceleration time may be limited. For details, refer to the following.
☞ Page 1098 Limit of acceleration time/deceleration time
*3 This is the calculation formula when the unit of V is [/s]. When other than [U/s], calculate by converting into [U/s].

- Jerk calculation

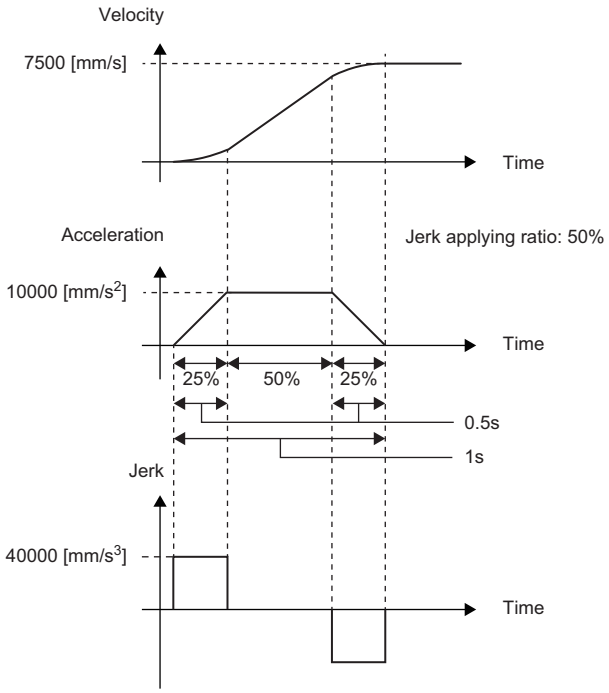
When the velocity and the acceleration of operation are fixed, the jerk can be calculated with the following formula by specifying the jerk applying ratio.

$$\text{Jerk (J)} = \frac{(2 - \text{Jerk applying ratio}) \times (\text{Square of acceleration (A)})}{\text{Jerk applying ratio} \times \text{Speed (V)}}$$

The acceleration section jerk applying ratio is the ratio of the jerk applying time to the acceleration time. The jerk applying time is the sum of the acceleration section 1 time and the acceleration section 2 time.

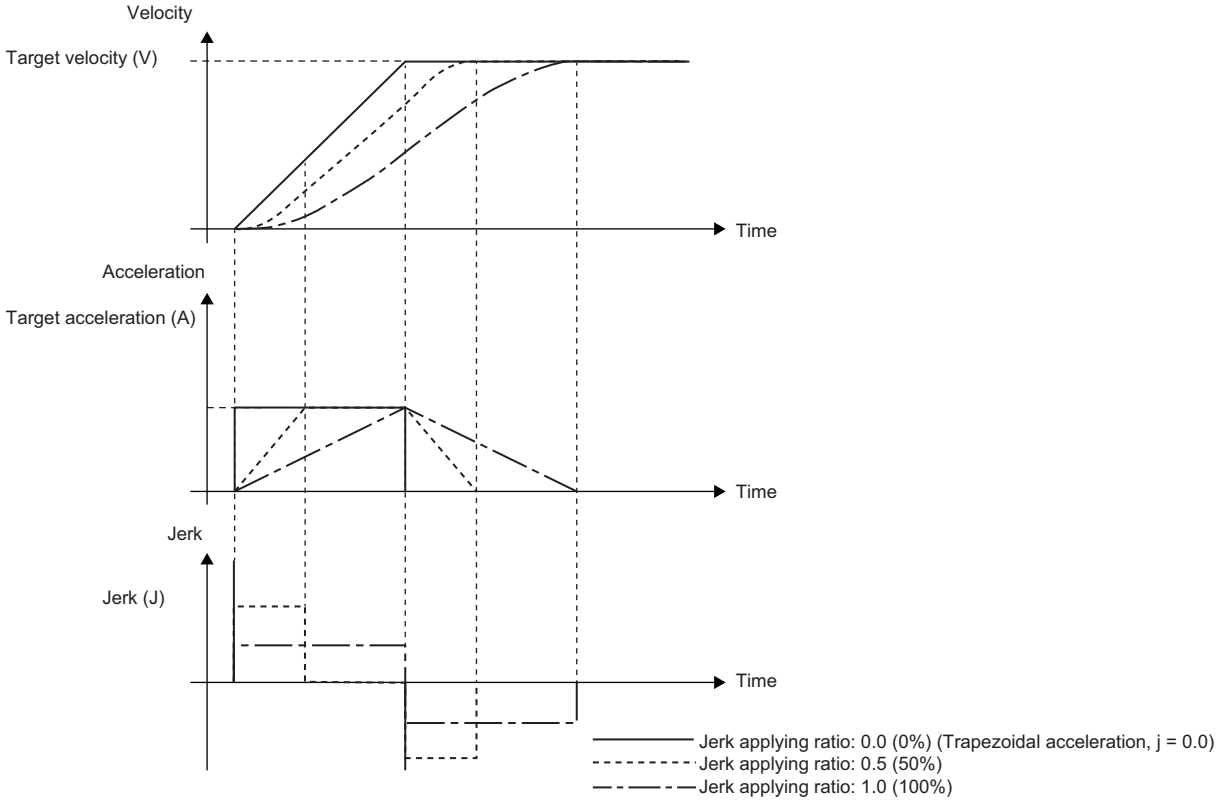
Ex.

When calculating the jerk with the following values set.



Item	Setting value
Velocity	7500 [mm/s]
Acceleration	10000 [mm/s^2]
Jerk applying ratio	0.5 (50%)

$$\text{Jerk (J)} = \frac{(2 - 0.5) \times 10000^2}{0.5 \times 7500} = 40000 \text{ [mm/s}^3\text{]}$$

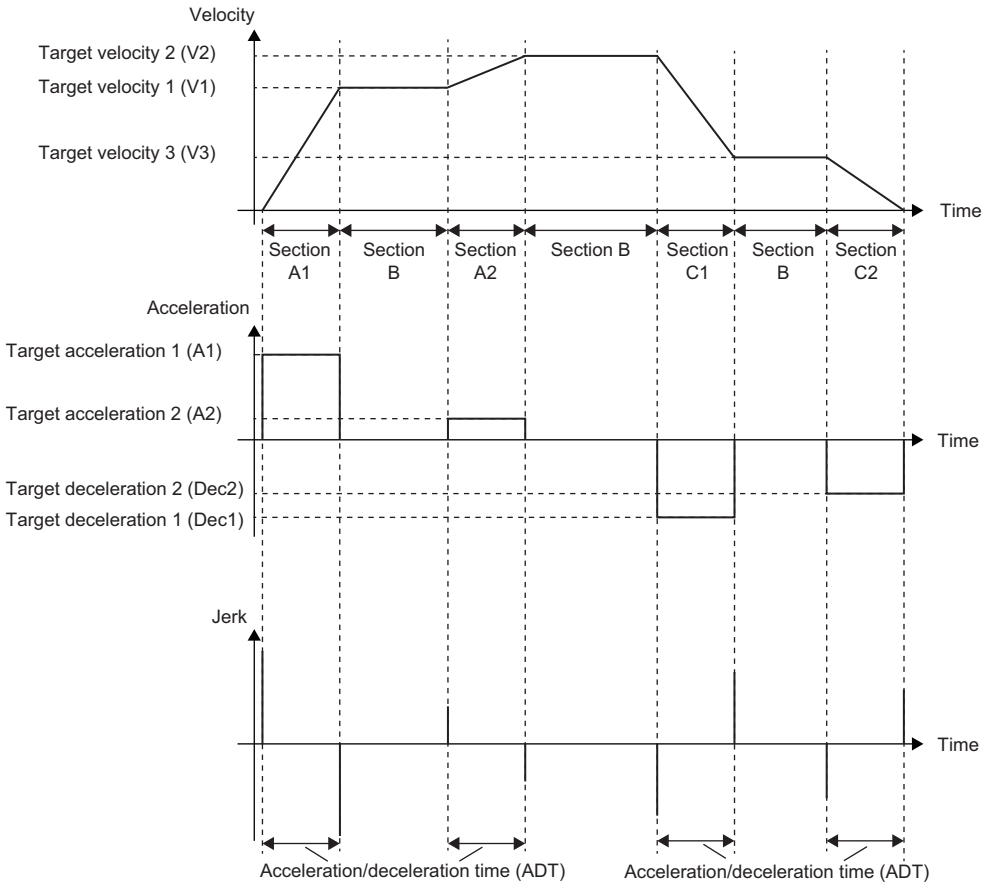


The acceleration time can be calculated when the velocity, the acceleration, and the jerk are fixed. For details, refer to the following.

☞ Page 1085 Jerk acceleration/deceleration

$$\text{Acceleration time (AT)} = \frac{\text{Speed (V)}}{\text{Acceleration (A)}} + \frac{\text{Acceleration (A)}}{\text{Jerk (J)}} = \frac{7500}{10000} + \frac{10000}{40000} = 1\ [\text{s}]$$

When the jerk applying ratio is big or the jerk is small, the acceleration time (deceleration time) becomes longer than that of the trapezoidal acceleration/deceleration. When the jerk applying ratio is 100%, the acceleration time (deceleration time) becomes doubled compared with the trapezoidal acceleration/deceleration. When setting the jerk, pay attention to the acceleration time (deceleration time).



Point

Since the velocity calculation is based on a given jerk, when the acceleration (deceleration) and the target velocity at FB execution are different from the acceleration (deceleration) used at calculating the jerk, the final acceleration time/deceleration time of control are calculated according to the calculation formula of the acceleration/deceleration time parameter.
If the jerk applying ratio exceeds 100% due to the acceleration (deceleration) or the target velocity at FB execution, the target velocity may be reached before the target acceleration is reached.
For details, refer to the following.
☞ Page 1092 Acceleration/deceleration waveform adjustment when specifying jerk

Acceleration/deceleration time-fixed method

When "1: Acceleration/deceleration time-fixed method (mcFixedTime)" is selected in the Acceleration/deceleration method setting (Options (Options) bits 0 to 2) of the FB, set the acceleration/deceleration time in Acceleration (Acceleration). Deceleration (Deceleration) and Jerk (Jerk) are not used.

Calculates acceleration and deceleration from the acceleration/deceleration time at acceleration/deceleration. When a value smaller than one operation cycle other than 0.0000 is set as the acceleration/deceleration time, the target velocity is reached in one operation cycle.

○: Operation possible, ×: Operation not possible

Section		Process description	Operation	
			Acceleration	Deceleration
A	Acceleration section	Acceleration is performed so that the acceleration time from the set velocity to the target velocity is the acceleration/deceleration time.	○	×
B	Fixed speed section	Control is performed at the target velocity. (Acceleration = 0.0)	×	×
C	Deceleration section	Deceleration is performed so that the deceleration time from the set velocity to the target velocity is the acceleration/deceleration time.	×	○

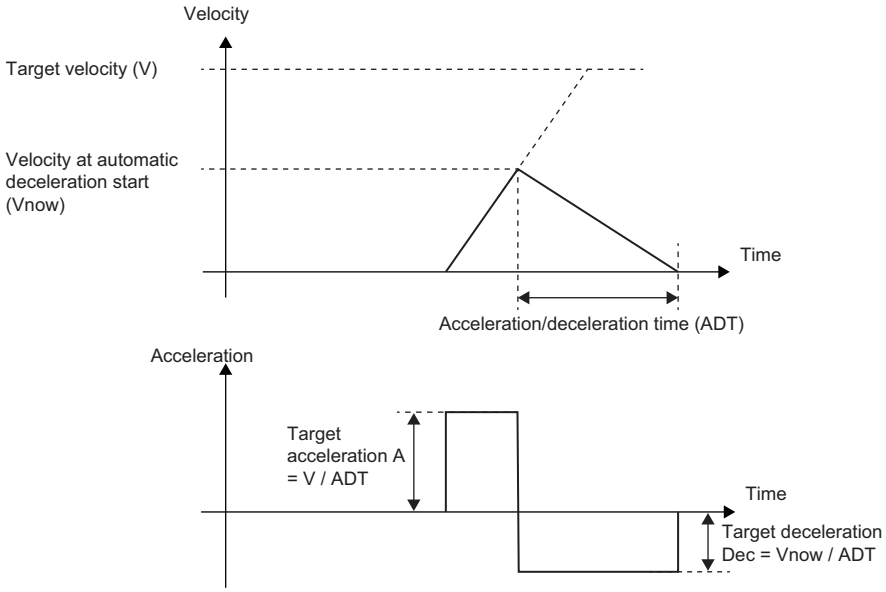
• Acceleration/deceleration parameter calculation

○: Operation possible, ×: Operation not possible

Type	Item	Abbreviation	Description	Calculation formula	Operation	
					Acceleration	Deceleration
Specified value	Target velocity	V	—	—	○	○
	Acceleration/ deceleration time*1	ADT	—	—	○	○
Calculation value	Current velocity	Vnow	The set velocity at target acceleration and target deceleration calculation	—	○	○
	Target acceleration*2	A	Acceleration from the current velocity to the target velocity*3	(V - Vnow) ÷ ADT*4	○	×
	Target deceleration*2	Dec	Deceleration to decelerate from the current velocity to the target velocity*3	(V - Vnow) ÷ ADT*4	×	○

*1 The deceleration time at automatic deceleration may be longer than the specified acceleration/deceleration time (ADT) due to the compensation of the remaining distance.

*2 It may exceed the acceleration limit value or the deceleration limit value. For details, refer to the following. If it exceeds the acceleration/deceleration range, it will be the upper limit value of the acceleration/deceleration.



☞ Page 1096 Acceleration limit value/deceleration limit value

*3 The target velocity will be 0 at stop.

*4 This is the calculation formula when the unit of V is [/s]. When other than [U/s], calculate by converting into [U/s].

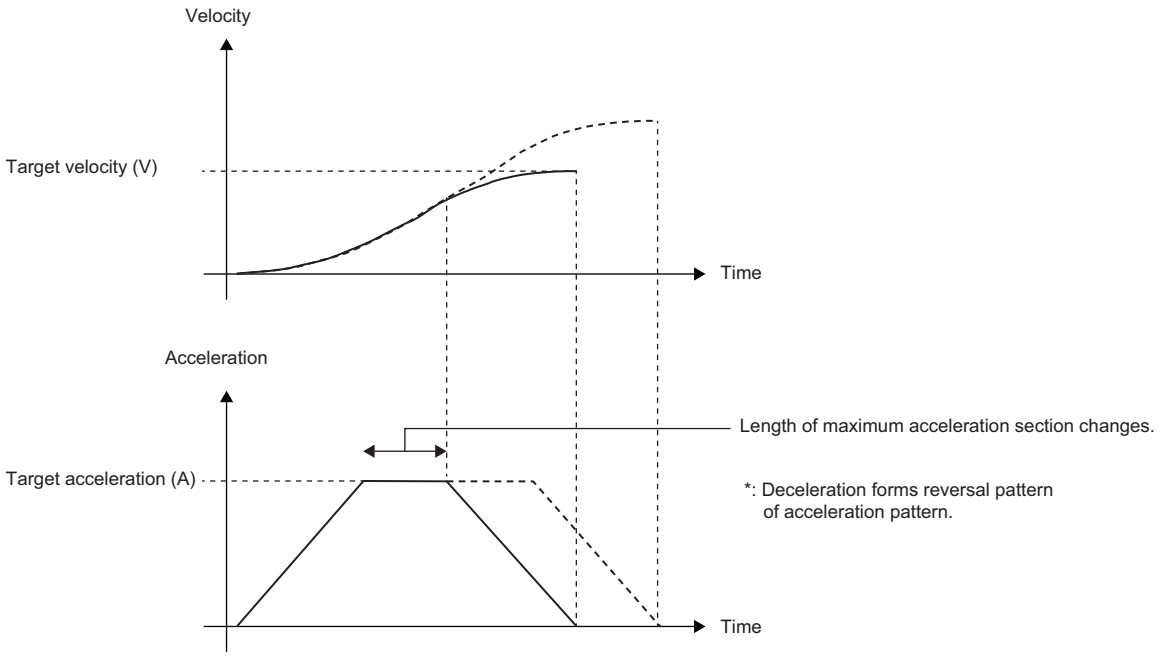
When the movement amount which does not allow acceleration up to the target velocity is specified at positioning operation, automatic deceleration will start to decelerate and stop at the target position while accelerating. In this case, deceleration is recalculated with the velocity at automatic deceleration start.

Set acceleration/deceleration specification method to set time-fixed acceleration/deceleration at acceleration/deceleration.

Acceleration/deceleration waveform adjustment when specifying jerk

When the jerk acceleration/deceleration (J ≠ 0.0) is specified, the acceleration waveform and the deceleration waveform are adjusted whether the values of the target velocity (V), the target acceleration (A), the target deceleration (Dec), and the jerk (J) satisfy the following condition or not.

Acceleration/deceleration	Condition
For acceleration	$V \geq \frac{A^2}{J}$
For deceleration	$V \geq \frac{Dec^2}{J}$



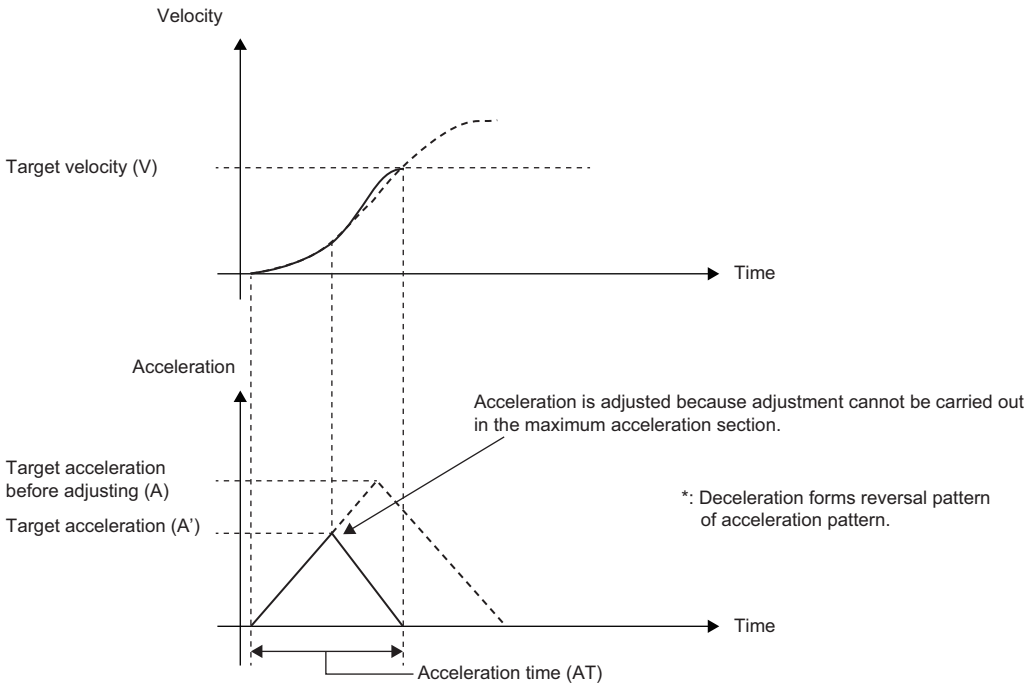
When the condition is satisfied

The target acceleration (deceleration) can be reached.

The maximum acceleration section time and the maximum deceleration section time are adjusted by the velocity, the acceleration, the deceleration, and the jerk, and the waveform changes to reach the target velocity at the end of acceleration.

For the acceleration time and the deceleration time, refer to the following.

☞ Page 1084 Acceleration/deceleration method



When the condition is not satisfied

When accelerating to the target acceleration, the velocity exceeds the target velocity during acceleration. Therefore, the acceleration is adjusted to reach the target velocity at the end of acceleration. (The velocity does not reach the specified target acceleration (deceleration).)

When the acceleration is adjusted, there is no maximum acceleration section, and the acceleration waveform becomes a triangle. Also, the same adjustment is applied to the deceleration.

Term	Abbreviation	Description
Target acceleration before adjustment	A	Target acceleration before acceleration adjustment
Target acceleration	A'	Target acceleration after acceleration adjustment
Target deceleration before adjustment	Dec	Target deceleration before deceleration adjustment
Target deceleration	Dec'	Target deceleration after deceleration adjustment

The target acceleration (A') and the target deceleration (Dec') can be calculated with the following formula.

$A' = \sqrt{V \times J}$

$Dec' = \sqrt{V \times J}$
